TO OUR READERS.

— x —

On a day early in the present century a little lad, son of a poor mechanic, was sitting on a bank in the small plot called a garden in an obscure street of London. He had "a fine rosy-checked Apple [we now use his own words], and as I cut it I observed the pips inside, and wondered what they were for. I asked, and was told that from them the Apple trees came. The desire to know was raised. I obtained a place in an orchard, and felt delight in watching the developments of nature. Then I aspired to learn about plants less familiar." He became part of the household of a nurseryman of strong religious convictions, and here was led to devote himself to missionary labours. He passed to the islands of the Pacific. He erected a residence.

"A garden was cleared and enclosed. A group of stately Chestnut trees that grew on the banks of the stream were left, as well as several Bread-fruit trees, to shade and adorn the homestead. Place was found for the newly-introduced plants and flowers, in addition to the most useful or beautiful indigenous productions of the soil. Orange trees were planted in front of the house, and a Citron hedge enclosed the whole. The writer, though scarcely five years old when removed from this home of his childhood, retains in his memory an indelible picture of the charming scene—the mountains, the beach, and the characteristic vegetation of the region—the plumed and towering Cocoa-nut, the spreading, loaded Bread-fruit, and the gigantic-leaved Banana; the bay, with its liquid crystal, the magnificent ocean beyond, and the mountains of Raiatou, like shadowy cloudland on the horizon."

The example was followed by the natives. "Plastered houses, neat gardening, and cultivated fields" accompanied conversion to the Christian faith. Ill health in the missionary's family compelled him to return to England, and he became one of her pastors. Around the residence

"The grounds were laid out in excellent taste, all formality being avoided; and the walks and planting so disposed as to increase apparently the space, and to retain some of the wild grace of nature with the order of a well-appointed garden. But the grand charm—the glory—of the scene was its Roses. They were evidently at home in the soil and locality, and as evidently the master spirit of the place loved them and knew how to grow them. The choicest varieties might be introduced without fear of failure. The endless diversity, the profusion, the beauty, and the delicious perfume which this queen of flowers diffused about the homestead—meeting the eye at every turn, climbing on walls or trellised arches, spreading a blaze of blossom over beds disposed among the turf, presenting here and there magnificent heads of exquisite bloom, or grouped or single standards, or nestling in unexpected nooks and corners—altogether gave to the comparatively narrow enclosure an attractive loveliness peculiarly home-like in its character. A small greenhouse, adjoining one end of the dwelling, was originally all the glass about the garden; but this was soon found insufficient, and it became necessary to build a house for their accommodation as well as for the exotic Ferns and other tropical plants that required a high temperature. The Orchids formed a marvellous assemblage of floral beauty. The missionary's name became familiar both among amateurs and professional horticulturists in connection with the new plants introduced by him from his new mission field, Madagascar, particularly that marvel among Orchids, the *Angræcum sesquipedale*, and the curious and delicate Lace-plant, *Ovibrandra fenestralis*. He was a frequent exhibitor at the flower shows of the Crystal Palace and Regent's Park, and never failed to carry off prizes. In thus indulging his taste for flowers he did not embarrass himself by an expensive luxury; but contrived by the sale of plants to make the conservatory pay at least its own expenses; so that there was never on this score an accusing conscience to upbraid him with extravagance."

Poultry, pets of various kinds, bees, were cherished by him and his wife. They each were distinguished literary characters, and at an age of nearly fourscore he ceased from his labours, and within a week she was resting by his side.

That missionary was the Reverend William Ellis; and we make this record because he is an example of many thousands, clerical and lay, who similar in acquirements and associated tastes from whom we gather information. They, like the missionary, are beneficial examples; they enrich our pages by their contributions; they lead improvements to their neighbours; and for them as well as for young professionals—aye, and old too—our staff strive to be useful. Their efforts are successful, as every day's post and from many lands tell us; and one quotation from a Victoria letter represents the whole—"My wife has said more than once, *that little Journal has taught us much, but it also brightens remembrances of home.*" Such testimony animates and invigorates your old friends

THE EDITORS.

INDEX.

ACACIA ARAMATA, 203; WHITE SCALE on, 203; grandis culture, 305
 Acinetas, 462
 Acorns in water, 426
 Adiantum, Capillus-Veneris culture, 14; Farleyense, 240, brown, 471, culture, 411, 505, soil, 319; culture and grouping, 272; not thriving, 471
 A-rides culture, 312
 Agave, hybrid, 369

From observations taken near London during forty-three years, the average day temperature of the week is 75.3; and its night temperature 59.2. The greatest heat was 97, on the 5th, 1852; and the lowest cold 35, on the 9th, 1862. The greatest fall of rain was 0.82 inch.

EVENING MUSINGS FOR PLAIN PEOPLE.—No. 6.
VINE CULTURE.

Continuation of the musings on the question of simplifying Grape-culture, so that all who have means may "grow their own Grapes," a sort of protectionist whisper suggests another matter. What are the trade-growers and fruiterers to do? First, the fruiterers sell but few Grapes to those who have gardens, and the trade-growers will find customers for all they can produce amongst those who have not gardens. I have always observed that those having gardens, and fruit happening to be scarce, are in the habit of purchasing a supply very begrudgingly. It is, after all, only natural that this should be so, as entering on a phase of housekeeping which had not been taken into account in their calculations. As a rule, a person having no garden will, according to his means, invest freely in all kinds of fruit, including Grapes, and eat and enjoy it without the slightest compunction; but depend upon it, if a person who might have a vineyard, and yet lacks this useful structure, happens to purchase a few Grapes, they may be remarkably good, but they are almost sure to have an unwelcome fruit-shop smack about them, and a nasty after-taste of perhaps 5s. to 10s. per pound to destroy their relish. No, this class will not buy Grapes, but scores may grow them who have not yet thought to do so, and if they have, they are only to be deterred by some subtle mysteries of culture, or haunted by pre-conceived or instilled notions of ruinous expense. Considering the mystery a myth, and the frightful cost non-existent, I with a clear conscience advise all who have the means of doing so to grow Grapes. It is urged on every point on the owner by possession of them for his own use, and a possible disposal of any surplus in his district market, and thus providing the public with that of which they will be glad to avail themselves at a reasonable cost, leaving the higher-class produce of skilled market-growers for the demands of those able and willing to supply themselves at its higher worth.

A more extensive adoption of plain simple Grape-growing would be benefit to many and injury to none. The tons of foreign produce imported every season are a sufficient proof that there is room for all that can be grown at home, and grown, too, at a cost remunerative to the vendor and reasonable to the purchaser. The practice is steadily growing for clergymen, professional men, and farmers to go into fruit-growing as a means of recreation and enjoyment, and it is all the more pleasurable if it pays its way. This is a hopeful sign. Some of them are turning their attention to Grapes, and the more who follow suit the better. A clergyman can preach no worse nor be less zealous in his important duties, a farmer farm no worse, a professional man be less active and useful, by engaging in a pursuit so pure and, shall I add, humanising? as any horticultural exercise. Experience, however, proves that such pursuits act beneficially as healthy

stimulants, assisting to a better and more cheerful fulfilment of the sterner duties and purposes of life.

There is one obstacle in the way of these pursuits being more freely and generally entered on. It is true it is only sentimental, but is yet in a certain degree formidable. We have the best authority as to one who could not dig, and to beg was ashamed; and there is not the slightest doubt, that in the matter of fruit, there are many who cannot give, and to sell they are ashamed; but strong-minded, clear-headed, and good-hearted men are breaking down such paltry barriers, and indeed it is time they did, and save the tons of fruit, that cannot be given, from rotting in the stores. There is nothing strained or imaginative here, but it is all hard and veritable fact; yet in saying this it is as freely admitted that there are many who can give and do give, many who have both the means and the will to do so. All honour to such men, and may their numbers increase; but of those who have the means to give or sell, and where selfishness forbids the one and pride the other, the sooner they are "educated" to a better and more reasonable course of action the better. Nothing can be more proper and legitimate, more reasonable and right, than that a clergyman, for instance, should turn to the best account the means at his disposal—that he should, if his inclination disposed him, cke out his, in many cases, scanty income by selling his surplus fruit. Many a one of his class would find a house of Grapes a source of profit and congenial occupation to himself, and would also confer a favour on his district by bringing this delicious home-grown fruit within the reach of his neighbours.

Not long ago a clergyman invited me to confer with him on his garden—a garden of fine soil. My advice was, Grow fruit freely. His reply was pertinent to the present subject. "That is just what I should like. I should enjoy it as a nice employment, but what am I to do with the fruit? I know what I should like to do, I should like to give some away—distribute it about where it might be needed or valued—and sell the rest to pay expenses. But, then, if I give to one I must give to all, not where I like, but where they like, or I shall not have peace, and if I sell it I shall get further wrong still, so am in a dilemma, and cannot decide what to do." I have given his words as literally as memory allows. Now, I have a very strong opinion, had the case been my own, that I should feel to have done ample justice to the position by considering it five minutes at the utmost, and then have gone on planting; but I am not a clergyman, being made, perhaps, of ruder stuff. However, he has planted, and I hope will live to eat, and give, and sell his fruit in peace. Amongst the rest he has planted Vines, and ought to plant more; he planted them just in the ordinary soil with evident misgivings, as he could not think they would grow in that way when everybody else carted soil and made borders; but he has had "proof of the pudding," and is satisfied now. The growth of these Vines is as perfect as one need wish to see, being remarkably stout and short-jointed, and with pith at a minimum. Not a vestige of turf, manure, bones, or other stimulant forms any part

of their feeding-ground, which is in all points similar to the rest of the garden, but, as before mentioned, the soil is good. Trees and shrubs grow with a healthy vigour, instead of exhibiting a plethora luxurians. Wherever this is the case Vines will grow, and are sure to produce a useful fruit, without the trouble and expense of a costly border or parterre, which is too often only an elaborate superfluity and a costly mistake.

This assertion, however, ought to be proved, and as one example is as good as ten, it shall be given. It will show how a border was spoiled, and this may possibly be as instructive as telling of the rectification of the error and how the new border was made. It will also show how to kill a house of Vines as well and as completely as a house of Cucumbers.

"I have made up my mind," said my pupil, "to build the viney, and want to know about the border, what I am to take out and what to put in without going to a great expense." In this case fair useful Grapes were required, and not grand exhibition specimens; indeed, with the best border in the world he could not have produced such. Being a plain man, and wanting only plain Grapes, he must have plain instructions. They proved too plain, and in trying to improve them surreptitiously he was driven to three things, and none of them particularly pleasant—viz., he nearly killed his Vines, begged my pardon for disobedience (of course as a bait to further aid), and incurred a cost of £20 in taking the spoiled border out and making a new one. The natural soil of the border's site was a brown loam inclined to be strong; it was a foot deep, rather rich by frequent manurings—just such a soil as would grow a capital crop of Wheat—and rested on a tenacious and nasty-looking marl. Would the Vine roots go into this subsoil; and if so, what then? Well, rather than incur the expense of removing it or concreting, I relied on the evidence of some Apricot trees growing alongside, which were perfectly clean, healthy, and fruitful, and simply counselled adding to the foot of good soil another foot of turf pared from the roadside, and all worked well together. No manure or other stimulant was judged necessary, but any given was to be applied entirely to the surface, leaving it to the Vines to choose between the hungry soil at the bottom and a rich feeding-ground at the top.

Now, for the carrying out these instructions, or rather the non-carrying out, and the penalty of disobedience. This was the commencement: "Now, my lads, for this border; get your barrows and tools. I've had Mr. Wright, but we can improve on him. He says, Work a foot of turf in. What's turf? I mean muck, and plenty of it. We will just top it with turf to take him in, and when he sees the Grapes he'll say, 'I told you the turf would do it, and muck was not necessary.' Then I shall have him with his manure only as a top-dressing; but I want muck at top, and bottom, and all through, and I mean to have it, and show the gardeners how to grow Grapes. They have about as many fancies as the doctors, who nearly killed my wife, and took me all my time to get her out again."

I advised, as the only way of saving the lives of the Vines, putting on 6 inches more of top-dressing, to be kept regularly moist, the top growth also to be kept moist and shaded. This was to induce the emission of roots round the collars of the Vines, and it succeeded. Every root that went into the border perfectly healthy in the spring was cut off in the autumn, and the new surface or stem roots encouraged to carry on the Vines.

Now to the future. Not many will triumph over the vanquished and leave them to their fate. But before a word of advice was given every spoonful of the spoilt border must come out. It was no small affair. It was entirely refilled with turf blackened with soot as it was put in, and mixed freely with lumpy charcoal. The owner has, in his abundance of Grapes, so far forgot his loss; and so far from the means of front ventilation being deficient, it has not been used to one-fourth of the extent it might have been, otherwise he would not produce such Grapes as he is now cutting. But this touches on another and distinct phase of Grape-culture, which must be deferred for another "evening's musing."—J. WRIGHT.

ROYAL HORTICULTURAL SOCIETY.

JULY 2ND.

The great Rose Show, which for some years past has been incorporated with the National Rose Show, closely followed Bath and the Crystal Palace, and was a decided success, the exhibitors being numerous, and the trusses shown of the highest merit. One unfortunate circumstance, however, threatened to mar the effect of the Show (which filled the two conservatory corridors),

and caused serious loss to the Society. We learned that the staging and green baize used at the Bath Show were dispatched from the Show ground at that city on Monday at one o'clock, and the railway company had not delivered the goods on Wednesday morning. The result was that staging had to be improvised, and much woodwork cut to waste, while in the morning trusses, tabling, and empty boxes were revealed in all their nakedness; but this was subsequently remedied before the public were admitted by the purchase of new baize, of course putting the Society to a heavy expense, which would not have been incurred had the goods arrived in reasonable time. Besides the Rose Show, the most liberal prizes offered by the Messrs. Veitch, amounting to £98, brought together, not the most extensive, but by far the best collection of fruits we have seen for years. Leaving these, however, for more particular notice further on, we will return to the Roses, taking the nurserymen's classes first.

In Class 1, seventy-two single trusses, Messrs. Paul & Son were first with splendid examples of Camille Bernardin, John Hopper, Louis Van Houtte, Etienne Levet, Ville de Lyon, Exposition de Brie, Marie Baumann, Alice Dureau, Duke of Edinburgh, Antoine Ducher, La France, Horace Vernet, Marquise de Gibot, Mlle. Marie Raly, Duc de Rohan, Marquise de Mortemart, Ferdinand de Lesseps, Leopold Hausburg, Dr. Andry, Vicomte Vigier, François Louvat, and Madame Thérèse Levet. These and others were very large and fine, but a trifle wanting in freshness. Second came Mr. Cranston, of King's Acre, Hereford, with fine trusses, mostly very fresh, among which we particularly noticed Madame Charles Wood, Marquise de Castellane, Exposition de Brie, Madame Laurcut, John Hopper, Victor Verdier, Le Rhone, François Michelon, Xavier Ohlo, Countess of Oxford, Etienne Levet, Duke of Edinburgh, Annie Laxton, Maurice Bernardin, Horace Vernet, Beauty of Waltham, Edward Morren, and Alfred Colomb. The third and fourth prize collections also contained many fine blooms of the above varieties, the exhibitors being Mr. B. R. Cant, of Colchester, and Messrs. Mitchell, of Pittdown. Mr. Keynes, of Salisbury, was likewise in the field. Mr. Cranston was more successful in the class for three trusses of forty-eight varieties, taking the first place with splendid trusses of La France, Prince Camille de Rohan, Edward Morren, Xavier Ohlo, Maréchal Niel, Duke of Edinburgh, Marie Baumann, Marquise de Castellane, Maurice Bernardin, Victor Verdier, Countess of Oxford, &c. Second came Messrs. Paul & Son; and third, Mr. Turner, of Slough, each with remarkably fine trusses; and fourth, Mr. Keynes.

For twenty-four varieties, three trusses of each, Mr. Turner was first with splendid examples of Ferdinand de Lesseps, Louis Van Houtte, and Prince Camille de Rohan; Messrs. Paul & Son second; Mr. J. Fraser, Lea Bridge Road, third, and Mr. Cant fourth. In the class for the same number, single trusses, the prizes went to Mr. Prince, Oxford, Mr. Cant, Mr. Turner, and Mr. Cranston.

Coming now to the amateurs' classes we found a remarkably good competition. First, for forty-eight single trusses, came T. Laxton, Esq., of Stamford, who had large and delightfully fresh trusses of Marquise de Castellane, Charles Lefebvre, Alfred Colomb, Mlle. Eugénie Verdier, Camille Bernardin, Dr. Andry, and these were only a few out of many equally good. Mr. Ingle, gardener to Mrs. Round, Birch Hall, Colchester, was an excellent second; Rev. G. Arkwright, Pencombe Rectory, third, and J. Hollingworth, Esq., Maidstone, fourth.

In the class for thirty-six trusses, Mr. Baker, Heavitree, Devon, maintained his Crystal Palace position by taking the first place with a stand of high quality. Mr. Ingle took the second place, showing very good trusses; the third and fourth prizes went to the Rev. G. Arkwright and J. Hollingworth, Esq. The last-named gentleman was first for twenty-four; Mr. Quennell, Brentwood, and J. E. Cavill, Esq., Walton Manor, Oxford, being also placed. The best twelve came from Mr. Tranter, Upper Assenden, the remaining prizetakers being Mr. Soder and Mr. Porter.

For twelve new Roses of 1871 or 1872, Messrs. Paul & Son were first, Mr. Cant second; third and fourth came Mr. Turner and Mr. Cranston. The most striking varieties in these stands were President Thiers, Madame Lacharme, Richard Wallace, Madame G. Schwartz, André Danand, Etienne Levet, Lyonnois, François Michelon, S. Reynolds Hole, and Annie Laxton. In the next class for six trusses of any new Rose of 1871-72, Messrs. Paul & Son were first with Etienne Levet, very fine; second, Mr. Cranston with Anguste Michelon; third, Mr. Cooling with Madame George Schwartz; and fourth, Mr. Keynes with Abbé Bramerel.

Tea-scented and Noisette Roses were shown in good force. The best collection of not less than twelve trusses of yellow Roses was that of Mr. Cant, which included Maréchal Niel, Gloire de Dijon, and Triomphe de Rennes, very fine; Mr. May, Stisted, was second, Mr. Chard third. In these were very fine examples of Céline Forestier, Triomphe de Rennes, and Maréchal Niel. For twelve Tea-scented and Noisette Roses the awards went to Messrs. Ingle, May, Wakeley, and Hollingworth

among amateurs; and to Mr. Cant, Messrs. Paul & Son, Mr. Turner, and Mr. Keynes among nurserymen. In these stands were beautiful trusses of Gloire de Dijon, Devoniensis, Madame Sertot, Rubens, Cheshunt Hybrid, Madame Willermoz, Maréchal Niel, Souvenir d'un Ami, and Niphetos. For six Tea-scented in bud, Mr. Cant was first, Mr. Bennett, gardener to W. W. Burrell, Esq., Cuckfield, second, and Mr. Turner third. There were classes also for Roses to be judged for their perfume. The prizes for six of any kind were adjudged to Messrs. Paul & Son, either for Abel Grand or La France; second came Mr. Turner with Abel Grand, and third Mr. Chard with Camille Bernardin. The next class was for six Tea or Noisette-Roses, flowers good of their kind, to be judged for perfume. Here Mr. Bennett was first, and Mr. Cooling second.

For twelve single blooms the prizes went to Mr. Turner, Mr. Keynes, and Mr. Cooling, the first two in particular having admirable examples.

The only two groups of pot Roses were from Messrs. Paul and Son and Messrs. Veitch, who each had plants beautifully flowered; those from the former firm were especially noticeable both for the size and freshness of their blooms.

Prizes were offered by Mr. W. Paul for six blooms of Princess Beatrice. Only one exhibitor—Mr. Farrow, gardener to G. Batters, Esq., Enfield, came forward, and he received a first prize, though his blooms did not do full justice to this truly fine variety.

Of other subjects Mr. Williams, of Holloway, sent a magnificent group of plants, many of which had already appeared at Bath. Messrs. Osborn, of Fulham, sent a group of Palms, Ferns, Lilium auratum, and Epiphyllum creatum with large white flowers. Messrs. E. G. Henderson contributed a large collection of Pelargoniums of the forcing type, hybrid Begonias, and Tree Carnations. Another collection consisted of Dr. Denny's splendid seedling Geraniums, the second set of which is in the hands of Mr. Copelin, Tyssen Street Nurseries, West Hackney. Mr. H. B. Smith, Ealing Dean Nurseries, sent a group of Petunias; Mr. Turner, of Slough, a collection of Pinks, Carnations, and Picotees which struck everyone with astonishment; also his fine new Show Pelargoniums, several of which had before been certificated, as well as Royal Standard Rose, globular, like Felix Genero in shape, but very much larger and of a bright rose colour. From Mr. Ware, Tottenham, came a fine group of Delphiniums, Pentstemons, and Antirrhinums; and from Mr. Forsyth, Brunswick Nurseries, Stoke Newington, Lobelia pumila grandiflora flore-pleno, a dwarf and compact double deep blue variety, which was exhibited some time ago by Mrs. Dixon and Co., of Moorgate Street, and then met with much approbation. Mr. Noble, of Sunningdale, again sent the beautiful Spiraea palmata; and lastly, Mr. Denning, gardener to Lord Londesborough, Norbiton, a group of Orchids, in which were extraordinary specimens of Anguloa Clowesii, Thunia Bensonii, and Epidendrum nemorosum.

MESSRS. J. VEITCH & SONS, of the Royal Exotic Nursery, King's Road, Chelsea, S.W., offered some handsome prizes for fruit. For the best collection in ten distinct kinds, three prizes of £20, £15, and £10 were offered; and one would almost fancy the large prizes had frightened exhibitors away, as the only collection was a poor one, and was disqualified through having an unripe fruit of *Musa Cavendishi*, although to it was awarded an extra prize of £5.

For the best dish of White Grapes, consisting of three bunches of one or more kinds, Mr. J. Douglas, gardener to Francis Whitbourn, Esq., of Loxford Hall, Ilford, took the first position with a very well-ripened dish of Muscat of Alexandria. The bunches were large, the berries large and well coloured. The second prize was awarded to Mr. W. Cole, gardener to J. S. Budgett, Esq., Ealing Park, W., for a very fair dish of Bowwood Muscat. Third, Mr. J. Woodbridge, gardener to the Duke of Northumberland, Lion House Gardens, Isleworth. Mr. M. Walker, gardener to H. J. Atkinson, Esq., Acton, had an extra prize for Muscat of Alexandria. And here we would remark on the shameful manner in which some of the Grapes had been cut. We noticed a dish of Canon Hall Muscat; the berries had not even swelled to their full size; they were positively green. A very good dish of Buckland Sweetwater was sent from Sir W. Farquhar's gardens, Polesden, Dorking. In Black Grapes the competition was very spirited, no less than thirteen dishes being exhibited, and the quality was excellent. The first prize went to Mr. J. Wakefield, Leamington, for a very well-ripened dish of Black Hamburgh, the berries even in size and splendid in colour. Second, Mr. J. Douglas, for a remarkably well-finished dish. Third, Mr. G. Sage, gardener to Earl Brownlow, Ashridge Park, Great Berkhamstead, also for a well finished dish of Black Hamburgh. Extra prizes were awarded to Mr. T. Rawbone, gardener to the Earl of Shrewsbury, Alton Towers, Cheddle, Stafford; and Mr. G. Holliday, gardener to J. Norris, Esq., Castle Hill, Blechingly, Surrey. Mr. A. Johnson, gardener to the Marquis of Ailesbury, Savernake Forest, Marlborough, showed three very large bunches.

The best three Fine Apples. In this class there was also a good competition, and all the exhibitors showed Queens. Mr. C. Rye, gardener to J. Deacon, Esq., Mableton Park, Tonbridge, Kent, had the first prize for three even-sized handsome fruit averaging 5½ or 6 lbs. Mr. G. Ward, gardener to T. N. Miller, Esq., Bishop Stortford, was second. He had a handsome Pley Queen of 6 lbs. Mr. G. T. Miles, gardener to Lord Carrington, Wycombe Abbey, had the third prize. Two other exhibitors took extra awards with good fruit.

Peaches.—For this prize eighteen exhibitors contested. Mr. G. Jackson, the Gardens, Tixall Hall, Stafford, was first with truly magnificent fruit of *Violette Hative*, the fruit of immense size and splendidly coloured; second, Mr. G. T. Miles with a good dish of what seemed to be Royal George; third, Mr. J. Barnett, the Gardens, Deepdene, Dorking. Two extra prizes were awarded.

Nectarines were not quite so high in quality as the Peaches, but seventeen good dishes were exhibited. The first prize went to Mr. W. Wallis, gardener to H. S. Thompson, Esq., Kirby Hall, York; the fruit was large but uneven in size and quality. Mr. G. Jackson, Tixall Hall, Stafford, had the second prize for Pitmaston Orange; the third went to Mr. Jack, gardener to the Duke of Cleveland, Battle Abbey, Sussex. Extra awards were given to Mr. W. Coleman, gardener to Earl Somers, Eastnor Castle, Ledbury, Hereford, and to Mr. G. B. Tillyard, gardener to the Earl of Yarborough, Brookesby Park, Lincoln. We do not question the awards of the Judges very often, but we would have placed the names of Mr. Jack and Mr. Coleman higher on the prize list. The Pitmaston Orange which received the second prize was not well finished, and the fruit itself is at best only second-rate, while the dishes of Elruge exhibited by Mr. Coleman and Mr. Jack were highly coloured and well finished.

Fruit-growers have to thank the Messrs. Veitch for the handsome prizes they have offered on this occasion, amounting to £98; and not only so, but we noticed that no less than ten extra prizes were awarded. And it was something new in fruit showing to see one of the firm with a handful of bank notes distributing the prizes as soon as they were awarded by the Judges. It is an old and true saying, *Bis dat qui cito dat*. We hope this will be an annual affair, and that next year collections will be exhibited worthy of the prizes offered.

Messrs. J. Carter & Co., offered prizes for the best six dishes of Peas, to include James's Prolific Marrow and Carter's G. F. Wilson. This prize brought out some excellent dishes of this useful vegetable. Mr. W. Cross, gardener to J. B. Lonsada, Esq., Sidmouth, Devon, had the first prize with Superlative, Omega, Popular, William I., James's Prolific, and G. F. Wilson. Mr. Moorman, gardener to the Misses Christy, Kingston-on-Thames, took a third prize. Mr. G. W. Bagnell, gardener to G. D. W. Digby, Esq., Sherborne Castle, Dorset, was fourth.

FRUIT COMMITTEE.—Alfred Smece, Esq., F.R.S., in the chair. Mr. Goldsmith, gardener to Sir Walter Farquhar, Bart., Polesden, Dorking, sent a fruit of a seedling Scarlet-flesh Melon called Improved Scarlet Gem. Mr. Bradley, gardener to W. Birch, Esq., Wretham Hall, Thetford, sent a new Melon called Wretham Hall. Mr. J. Cross, Gardens, Melchet Court, Romsey, sent a very handsome Melon called Read's Scarlet-flesh. It was remarkable as one of the richest flavoured red-fleshed Melons ever exhibited, and was awarded a first-class certificate. Mr. Sage, the Gardens, Ashridge Park, sent a dish of Pigs, which the Committee considered the same as Early Violet. Mr. Douglas, the Gardens, Loxford Hall, Ilford, sent a seedling Grape from the Black Hamburgh crossed by the White Frontignan, which was not in condition, and opinion was postponed to a subsequent meeting. Mr. Bunbury, the Gardens, Colham Hall, Gravesend, sent a brace of Cucumbers raised from crossing Luton Hoo and White Spine. Messrs. Veitch and Sons, of Chelsea, sent a large collection of twenty-six varieties of Cabbage Lettuce, and eighteen varieties of Cos Lettuce. They also exhibited a collection of twelve varieties of Garden Turnip, to which a cultural commendation was awarded.

The Committee met at Chiswick on the 21st of June to examine the Peas. They confirmed the decision of last year, that Emerald Gem is the same as Danecroft Rival. A first-class certificate was awarded to Dazuar, a white wrinkled Pea of dwarf habit, as early as Dillistone's, and which was raised by Mr. Laxton. A similar award was given to Mr. Laxton's The Slab, a white-wrinkled Marrow of medium growth, also very early. Another meeting was held on the 1st inst., when first-class certificates were awarded to The Baron, a blue Marrow, having pods nearly as large as Superlative, better filled, and ten days earlier; also to Laxton's Gem, a great improvement on Little Gem, being longer and more curved on the pods, and also much earlier than that variety.

FLORAL COMMITTEE.—W. R. Kellock, Esq., in the chair. The subjects submitted for adjudication on this occasion were far from numerous, and but few of them claim special notice. Messrs. Veitch sent a collection of Escallonias, of which *E. sanguinea* with deep red flowers and shining ovate leaves, had a first-class certificate. The same award was made to Mr. Muller,

Brunswick Nursery, Tottenham, for *Aristolochia floribunda*, more ornamental than most of the Birthworts; to Messrs. E. G. Henderson for Begonias *The Shah* and *Dr. Masters*; to Mr. Ware for light blue *Delphinium* Cambridge; and to Messrs. Stacey & Son, Great Dunmow, for *Verbenas* *Lady of Lorne* and *Countess of Rosslyn*; the latter bluish, with a purple centre, fine frass; the former bluish tinged with purple towards the centre, and the tips of large size.

Messrs. Paul & Son sent Cheshunt Hybrid and other new Roses which have been noticed before; Messrs. Cutbush, Tree Carnation Mrs. Robert Barclay, a showy scarlet kind, excellent for decorative purposes; Mr. Wilkinson, Guildford, Mr. Fraser, Lea Bridge Road, and Mr. G. Smith, Edmonton, seedling Zonal Pelargoniums, and Messrs. Osborn seedling Petunias. Messrs. Barr & Sugden, of Covent Garden, contributed a charming basket of Lilies, Irises, and Ixias; and Messrs. Teutschel, of Colchester, sent some varieties of *Lilium Thunbergianum*. From Mr. Pizzey, gardener to Sir E. Perry, Bart., Fulmer, came excellent stands of Pinks.

SHADES AND SHELTERS.—No. 1.

SHADING and sheltering are so combined and so essential as a means of protection against the many injuries which plants may receive, that the two subjects may be dealt with in one paper. It is not my intention to enter into the subject scientifically, but the main object of this paper is to impress upon the reader the great advantages to be derived from a general system of shading and sheltering.

The principal advantage of shading is to protect plants under glass from the fierce rays of the midday sun. When so used it does good, and it likewise favours the growth of plants by preventing rapid evaporation and consequent exhaustion. Plants in bloom are greatly prolonged in beauty and vigour by shading, but shades properly managed need as strict attention as air-giving; it is as possible to give too much shade as too much air, and very few would shade their plants in the absence of sun, neither ought they to allow shading to remain over their plants long enough to diminish the amount of light the particular class of plants stand in need of. Hence the objection, in many cases, to a permanent shading, such as lime-wash on the glass, &c., that it is there when often it is not wanted. The material which constitutes the shade should not be so thick as to darken the house and obstruct the free access of air and light; plants will not flourish under such treatment. An excellent material is to be found in a thin light canvas sold by all nurserymen; it is cheap and durable, and is sold in different widths to suit large or small houses, or it may be purchased as manufactured, and made-up by the person using it. There are other materials of a coarser texture frequently used for the purpose, also cotton bunting, and sometimes an article called *frigi domo*, which will be noticed hereafter, but none has been found to equal the thin canvas, which, with proper care, will last for several seasons.

Fig. 1 is part of a glazed roof and shows one of the first systems brought out for shading plant houses. Its only recommendation is, that it is effectual, but the plan of fixing and

Fig. 1.

working exhibits a need of improvement. This improvement is shown in *fig. 2*, where the wooden rod or pole upon which the blind is rolled has a wheel at each end instead of at one only, as in *fig. 1*. These wheels have a groove in which the cord works. One end of this is first nailed to the top of the house opposite the wheel, and supposing the blind to be down

the cord is brought down and inserted in the groove, then taken back and passed through an iron or brass roller fixed at the same place, leaving enough length of cord to come back over the roof of the house again. Having fixed the other end of the roller in the same way, to draw-up the blind we have only to pull the cord ends, and the canvas rolls round the rod in a very neat manner. This is done from the front of the

Fig. 2.

house. In letting down the blind it is only necessary to loosen the cord from its fastening, and the blind will run down of itself.

After accomplishing thus much it soon became obvious that still further improvements might be made in this system, by extending the length of the pole to 30 or 40 feet, or the length of a whole house instead of one light, or a small portion of the house, as shown in the illustrations. This was found to answer admirably, and to complete the whole arrangement it seems only to require a covering for the blind when rolled-up and not in use. This can be effected by a coping-board on the top of the house, under which the blind lies protected from all weather. I ought to mention that after making the canvas of the required size to cover the roof, one side of it is nailed to the woodwork under the coping, or permanent hooks may be inserted in this part at equal distances, and the blind provided with rings at similar distances and thus made fast. After this the other side is nailed to the wooden pole, and when the blind is rolled-up it may be held in its position by making the cord fast to an iron bracket inserted in the place where the operator stands. At many places the wheels at each end of the pole are dispensed with, and the cord put round the

Fig. 3.

pole instead. There is a disadvantage in this, for the cord working over the canvas soon wears it in holes, and without a wheel to clear the pole from the roof of the house, propelling it up and down will soon wear it out. The above system of shading can without difficulty be applied to houses of any length. On small pits and frames, which generally stand at a much lower elevation, a thinner and lighter material such as patent cotton-netting creates enough shade, but whatever be used it will be found best to adopt the same system or nearly

so of applying it, excepting that no cords or pulleys are required; each frame should have its length of shading nailed to a small, round, deal pole on one side, and the other side ought to have rings at equal distances corresponding with small hooks in the top of the frame lights. The rings being fastened to these, the blind will run down by its own weight. When not wanted it can be rolled up by the hand and put away under cover. Each blind, or shading, should have a number attached corresponding to one on the frame to which it belongs.

Next to house-shading comes that of shading individual plants or flowers. *Fig. 3* is a very simple and useful contrivance for that purpose. A piece of cardboard, thin tin, or even thick brown paper is shaped-out as at 1, and half of one of the longest sides is fastened to the stick as at 2, and tied at the top, then the upper corner of the narrowest end has a string attached, which when pulled and tied at the bottom forms the shape as shown at 3. This, with a stake of the proper length, is ready to place over any flower that it is wished to shade.

Fig. 4 is another form of shade, and, I think, an improvement on *fig. 3*. It is a circular one about a foot in diameter,

Fig. 4.

made of tin, and in the form of a dish-cover. A socket is attached to it at *a*, fastened to the top of the cover at *b*. In this socket the handle is inserted which supports it in the ground. Those who have tried this prefer it to any other for Roses, Dahlias, &c.

Although it is not expensive yet there is a cheaper way of making such covers. I call them home-spun ones, for I have set the men to make them in the winter. It is this, a frame is shaped-out with small wire to which painted canvas is stitched; the socket which holds the stake is in the centre at top instead of at the side, as in *fig. 4*, and is merely a stout piece of elder wood with the pith taken out; this is also painted, and the canvas is bound round it with small wire. I do not advocate this in preference to the former one, but because of its cheapness it is worth recommending. When out of use a lot of them can be stored away by stringing them on a rope run through the socket-eye, and the stakes put away for another year; they will last many years.—THOMAS RECOMB.

SHORTCOMINGS AT THE BATH EXHIBITION.

MAY I, with due deference to the Royal Horticultural Society and its executive, call attention to certain things at the late Show at Bath, which struck me as exceedingly poor and deficient? First, I may remark on the narrowness of the tents put up for the fruit and cut flowers, the vegetables, and the table decorations. These were supposed to be 30 feet wide, but were considerably under that mark. They were low and ill-ventilated. No barriers were erected to separate the crowd at the entrance and exit, so that when wishing to get out of a tent one had to face a mob wishing to get into it. Only light ropes on iron stays, screwed into the boards which formed the staging, were used to keep the crowd back; these ropes were so weak and pliable, and the stays so far apart, that the crowds were forced nearly on to the flowers. There was far too little space in the first instance in these tents for the exhibitors and attendants when staging the plants and flowers, and far less for the crowd. Then, in the centre tent, no attempt was made to hide the hideous forest of wooden posts made of

rough deals screwed together. There was neither paint, nor distemper, nor anything whatever done to relieve their naked ugliness; even a few wreaths of evergreens, or a flag or two, or anything, in fact, would have been better than nothing. Then what few large plants there were—and the fine specimens exhibited by Messrs. Cole and Baines were worthy of all praise—were not made the most of; instead of being arranged in two centre masses in the middle of the tent, where persons might have admired them from all sides, they were placed on one side the tent. The only *coin d'arrantage* from which a general effect of the tent might be seen was blocked by specimen plants. The Fuchsias, which were exceedingly good, were arranged at one end, and all the small plants were put into the centre, which, being depressed, and having a feeble fountain in the middle (which, with the taps here and there, wetted the walks and made all in a puddle), had on the whole a very meagre appearance.

But I have a still worse complaint to make. No arrangements whatever seem to have been made for the gardeners and exhibitors; no congress, no conversazione, unless we except the microscopic *soirée*, to which no gardener had any special invitation, but to which one could go by the payment of 2s. 6d.; no tent set apart in the ground, no place reserved for the Judges, exhibitors, Fruit and Floral Committees to dine together the first day of the Show under the auspices of the Council; no attempt, in short, that I could see whatever to make the Provincial Exhibition of the Royal Horticultural Society what it might be, not only the first and finest exhibition in England, but a place of *réunion* for horticulturists, where the working bees of the gardening world might feel that something was being done to encourage them and to elevate them. The worthy Director of floral shows has not sufficient authority placed in his hands, nor efficient workers under him to carry out the arrangements of a great show. If the number of classes, and the number of prizes given in each class, were somewhat reduced, the Exhibition would not be injured, and money might be forthcoming to put up additional accommodation for the Floral and Fruit Committees, the Judges, exhibitors, and Fellows of the Society. Parsimony in the direction I have alluded to is no true policy, and if these provincial exhibitions of the Royal Horticultural Society are to be looked upon in any other light than the means of getting money to defray home expenses, or as advertising mediums for nurserymen and makers of horticultural appliances, the sooner the present state of things is remedied the better. When no one is to blame everybody is to blame, and I think the error only arises from there being no committee of management appointed from the officers of the parent Society, and the Local Committee having, as a general rule, no official status, so that no one thinks it his duty to stir in the matter. I have heard, however, complaints both just and deep, and I think what can be done at Manchester, York, Leeds, Bishop Auckland, and elsewhere might also be achieved by the Royal Horticultural Society, and I hope another year may see a real improvement in this matter.—C. P. PEACH.

ROYAL HORTICULTURAL SOCIETY'S BATH SHOW.

ROSE SHOW.—As I supposed, the prizes offered on Thursday, June 26th, brought together a large number of exhibitors and some remarkably fine stands of Roses, the western growers having, probably, the advantage, inasmuch as the season being backward, and their climate more forward, they had the better chance of cutting blooms for so early a date; and it was not surprising to see Mr. Crauston come out so strongly as he did, and take the foremost place, beating easily Messrs. Paul & Son and Turner, who were his principal competitors; while the excellent blooms of Mr. Baker and Mr. Cann, and the Teas of the Rev. J. Handley showed how well private growers have studied and practised the cultivation of the queen of flowers.

A great deal of dissatisfaction was expressed at the non-admission of the public at the time specified. This arises from two causes—first, that exhibitors are so long in staging, and in this case the railway trains were disappointing; and second, from the paucity of Judges. Why in the world it should be considered necessary to have only two sets of Judges I cannot say, except that the Royal Horticultural Society can always only move in the same groove unless some pressure is put on. There were numbers of persons there who were thoroughly qualified to act as judges, and by the expenditure of a few pounds the evil might have been remedied. I daresay some kind friend will say, "Oh! he wanted to be judge himself," but that was simply impossible. I had to leave by twelve, and was too fully

occupied in getting notes to attend to anything else; but I felt those in the tent who were quite competent to have judged, and a good deal of annoyance might have been spared. But I suppose it is something like what was told me when I urged that it would be as well to publish the certificates with the list of prizes. "It is simply impossible." And yet the Royal Botanic Society does it after every show! I am sure of this, that the classes for nurserymen are quite enough for any two judges, and that the smaller classes for Teas, new Roses, &c., ought to be deputed to another set, different from those who judge amateurs; in fact, if the Royal Horticultural Society would condescend to take a lesson from the Crystal Palace it might be well for them.

Roses in pots were only contributed by Messrs. Paul & Son, who had nicely-bloomed dwarf plants of Anna Alexieff, Général Jacqueminot, Gloire de Dijon, Sénateur Vaisse, Elie Morel, Mons. Noman, Beauty of Waltham. Exposition de Brie, John Hopper, Marquise de Gibot, Horace Vernet, Duke of Edinburgh, Claude Million, Camille de Roban, Ferdinand de Lesseps, Madame Fillon, and Victor Verdier.

In the class for seventy-two, Mr. Cranston, of Hereford, easily took the first prize with some very fine blooms, amongst the best of which were Marquise de Gibot, a Rose of 1870, but which has, as far as I know, been rarely seen before this season; it is of a fine clear rose colour, and half-globular in form. Dupuy-Jamain, Marquise de Mortemart, Lelia, Princess Beatrice, Auguste Neumann, Dr. André, Horace Vernet, Comtesse d'Oxford, too large and coarse to please me; Catherine Mermet, Jean Cherpin, John Hopper, Marguerite Dombraïn, Esmeralda, Edouard Morren, Princess Mary of Cambridge, Baroness Rothschild, Niphotos, Duke of Wellington, Duke of Edinburgh, Henri Ledebaux, François Lacharme, Henri Pages, large but dull in colour; Marie Baumann, Louisa Wood, very bright; Maréchal Niel, Julie Touvais, an immense Rose; Maurice Bernardin, Charles Rouillard, Caroline de Sansal, Niphotos, La France, and Madame Margottin. Messrs. Paul & Son were second with Mdlle. Eugénie Verdier, remarkable in colour; Madame Rivers, Madame Clert, Madame Clémence Joigneaux, Abel Grand, Jean Cherpin, Duchess d'Orléans, Sénateur Vaisse, Madame Boll, Exposition de Brie, Annie Laxton, a remarkably pretty flower and of good quality; Alba rosea, Vicomtesse de Vesins, François Louvat, Maréchal Niel, La Fontaine, Alba rosea, Marguerite Dombraïn, &c. Mr. Charles Turner was third with Camille de Roban, La France, Fisher Holmes, La Fontaine, &c. In the class for forty-eight trebles, the same exhibitors occupied the same positions, and in twenty-four trebles also. Mr. Cranston has Niphotos, Duke of Edinburgh, Marguerite de St. Amand, Louisa Wood, Madame Knorr, and Lord Clyde. In the class for twenty-four single blooms, Hybrid Perpetuals only, Mr. Cranston was again first with Edouard Morren, Horace Vernet, Marguerite de St. Amand, Princess Mary of Cambridge, Julie Touvais, Marquise de Castellane, Charles Lefebvre, Nardy Frères, Dr. André, Comtesse de Chabrillant, Baroness Rothschild, John Hopper, La France, Victor Verdier, &c. Mr. Turner was second, and Mr. Cooling, of Bath, third.

Amateurs exhibited in strong force. The Rev. J. B. Camm was first with Marguerite de St. Amand, Souvenir d'Elise, a most lovely bloom; Narcisse, Duchesse de Caylus, Reine d'Or, very lovely; Triomphe de Rennes, Marquise de Castellane, Pierre Notting, Edouard Morren—I have never seen this variety so well shown as by Mr. Camm—Fisher Holmes, Boule de Niece, a very grand bloom, Prince Camille de Roban, Elie Morel, Maréchal Niel, Dr. André, Duke of Edinburgh, Abel Grand, Charles Lefebvre, Centifolia rosea, Marquise de Mortemart, Camille Bernardin, Souvenir d'un Ami, Marie Baumann, Madame Clémence Joigneaux, Madame Vidot, Madame Charles Wood, &c. Mr. Baker, of Exeter, had a fine box in which the flowers were, however, a little too coarse, containing Henri Ledebaux, Baron Gonella, Madame Haussmann, Charles Lefebvre, La France, Maréchal Niel, and others. Mr. Laxton, of Stamford, was third. In the class for thirty-six, Mr. Baker was first with Marguerite Dombraïn, Souvenir d'un Ami, Lord Macaulay, Lyonais, &c.—D., Deal. [Remainder of notes on Roses next week.]

HARDY TREES AND SHRUBS.—One of the most notable features at Birmingham last year proved to be the splendid collections of these exhibited in the grounds by Messrs. Barron, of Elvaston, and others. There were on this occasion no entries in the large classes; and in that for single specimens Mr. Cooling, of Bath, sent *Piota orientalis elegantissima*; Mr. R. T. Veitch, of Exeter, *Taxus elegantissima*; and Messrs. Maule & Son, a specimen of *Thuja aurea*. But worthy of special notice in this class of plants was the collection sent by Mr. Maurice Young, of Godalming. He had, at considerable expense, sent a quantity of old stumps and other materials to form a roofery at the entrance to the large tent. The outer margin was formed of low-growing plants and hardy Ferns, the other portion of the space being very judiciously and effectively planted, mostly with Japanese evergreens and Maples. *Euonymus elegantissimus* was very pretty in its white variegation; *Piota semper-aurea*, a fine dwarf golden

species, which Mr. Young thinks superior in effect to *Thuja aurea*; *Raphiolepis ovata*, a handsome evergreen shrub with white flowers and glossy deep green leaves, it has black berries in winter; *Retinospora plumosa aurea*; Young's Golden Chinese Juniper, *Juniperus chinensis aurea*; *Ligustrum coriaceum*, a handsome Privet; *Cryptomeria spiralis falcata*; and to add to the effect some improved seedling *Acubas*, one of them with thick, leathery, deep green leaves, which will be well adapted for planting in exposed positions. Mr. Young must be congratulated on the success of his exhibition. His plants are thoroughly well grown, and as far as we are aware he has been the first to hit upon this plan, which shows these extremely pretty Japanese plants to the best advantage. Mr. Fowler's Castle Kennedy, sent a basket of small plants of his *Abies Douglasii Stairii*, the young growths of which are creamy white, and are said to change to a green colour in winter.

SUPPLEMENTARY FRUIT SHOW.—On June 26th there was a supplementary exhibition, the same exhibitors staging in nearly every case inferior examples to those put up on the first day of the Show. Mr. W. Coleman, Eastnor Castle, sent a collection of very good fruit—Black Hamburg Grapes, excellent Peaches, Brown Turkey Pigs, Elruge Nectarines, and a Melon. Mr. W. Cox, of Madresfield Court Gardens, came in second with a nice collection. Mr. Coleman and Mr. Cox also exhibited the best Grapes. Prizes were offered by Messrs. Carter for examples of the new Melon, Little Heath, sent out by them for the first time this season. The best came from Mr. Gilbert, gardener to the Marquis of Exeter, Lurghley, Stamford.

TABLE DECORATIONS.—In our remarks on the Royal Horticultural Society's Show at Bath last week, we only cursorily noticed the table decorations. We intend now to call attention to them rather more fully, for, though they did not make so decided a feature of the Show this year as they did at Birmingham in the last, yet there were some especial features with regard to those exhibited this year to which we wish to allude.

There were only five exhibits this year, and these may be divided into two classes, two that were utterly meagre, poor, and thin, and three that were overloaded with decorations. One of these last was exceedingly meritorious if it had not been for the napkins. Even though many persons might object that even without the napkins, and the loose flowers stuck into them, the rest of the table was crowded, yet the arrangement of the flowers was exceedingly good, their quality unexceptionable, and the fault of redundancy is certainly on the right side. One which received no prize at all had certainly nothing to recommend it, either with regard to the arrangement of the flowers or the fruit; the glass vases laden with glass balls set on a centre of reflecting glass were decidedly meretricious in their glare. There was one redeeming feature in this table, which was exhibited by Mrs. Beck, of Milsom Street, Bath, and that was the carafes for water of a classic Pompeian or Egyptian pattern, standing in a light silver stand, supported by silver wire, having glass heads as pendants. These were certainly good, but the rest of the adornments of the table, which we shall refer to again, were decidedly of the shabby showy order. After these preliminary remarks we will go more into detail with regard to each of the different entries, and will take them in the order in which the prizes were awarded.

The first prize was adjudged to Miss C. Harris, Clarendon Park, Salisbury. There were three centre vases; and by the way we may remark, that all the exhibits, except Miss Blair's, had three vases for centres, as prominent features—one central, and two sides ones balancing. On Miss Harris's table the three vases were similar in height and design, though the ornamentation was somewhat different. This we consider a mistake in the first instance, as in no case should the two side-centre vases be so tall as the centre one. Miss Harris's vases were a flat glass on the table, with a tall slender glass rising from it, and three small side glasses hanging on bent wires, standing out at right angles from the centre of the stem of the tall glass. The principal vase had a spray of *Bougainvillea glabra* in the centre, with a little *Dielytra spectabilis* and *Verbascum*, and three tall common field Grasses, standing out above it, mixed below with Quaking Grass; the three little side glasses had each a spray of poor *Fuchsia* with a bit of the flower of *Cerastium tomentosum* and a little Maidenhair Fern. The base of the vase had heavy masses of *Adiantum farleyense* splayed flat on the table, a Fern which we hardly thought before could be used with bad taste; *Oncidium flexuosum*, purple Iris, a little hardy yellow *Azalea*, and flowers of the common Laurel put in to imitate Lily of the Valley. The two side vases had white Everlastings and *Acroclonium roseum* mixed with grass; the side pendant glasses, *Cerastium* and *Fuchsia*, the same as the other, and the base rather better arranged, as it had some pretty flowers of *Kalmia latifolia* to help to set it off. There were four small glasses with Iris and Fern, and buttonhole bouquets, which were neatly made up for each of the guests. With regard to the Iris we may remark that they were of that particular shade of colour which turns nearly black by gaslight. There were eight dishes of fruit, top and

bottom Melons and Pines, which looked fairly good. The rest of the fruit was utterly bad; two dishes of Grapes both unripe; Strawberry-bird; Apricots small and unripe; Oranges, and Apples. If simplicity and privacy of idea with meanness of fruit was what was to be aimed at, then the first prize was justly awarded to the first prize, even if it is not the best. But, which we describe next, was a very good one; but in this case there was something for the guests to eat.

The second-prize table, exhibited by Miss Blair, 50, Upper Bedford Street, Russell Square, London, is soon described. In the centre was a March stand flat on the table for a base, a small flat glass, about 18 inches in all, with a taller vase rising out of it—in fact, an ordinary March stand with a vase rising out of the top one. The centre was nicely decorated, having at the base white Water Lilies alternately with Cactus, and relieved with white Gloxinia, mixed with Ferns and Grasses. On each side of the centre vases there were two small Palms put through the table—a practice which we hope will soon be exploded—with two small segmental glasses put round the Palm to hide the folds of the tablecloth, filled alternately with blue Centaurea and white Pinks; there were twelve tall glasses holding single flowers, or buttonhole bouquets for the guests, set in finger-glasses, in which were floating a few odd flowers of Borage and sprays of Lycopodium. On the whole, though there was a decided paucity of decoration, yet the arrangement was more tasteful than that we have before described; the fruit was better, and we do not think we should have been so tired of the decorations at the end of the dinner as we should have been in the previous case in looking at bad Fuchsias, Grass, and Cerastium.

The next in order of merit (according to the Judges' award) was that of Mr. W. C. Armstrong, Cheltenham. In the centre was a tall vase rising from a flat dish, having six cornucopia-shaped vases extending as branches from the middle, three taller, three intermediate. This was standing on a silvered glass having eight segmental glasses arranged like a double quatrefoil to encircle it; in each of the quatrefoils were figures alternately of a little Cupid, each holding a basket in which were single Peaches, and swans in the alternate quatrefoils, floating apparently on the glass mirrors. The upper vase had *Spirea japonica*, *Paneratium*, *Begonia boliviensis*, all good, with pieces of rather poor scarlet Geranium mixed with them, which might easily have been dispensed with. The cornucopia suspended glasses were dressed alternately with pink and scarlet Geraniums, mixed with *Adiantum*, *Spirea*, and *Begonia fuchsoides*. The flat vases had *Ixora*, *Dipladenia*, *Eucharis amazonica*, *Roses*, *Lælia purpurata*, with an edging of Fern, the flowers though good being rather too crowded; and with the swans and boyish Cupids, segmental glasses, &c., this centre piece was overdone. The two side pieces were somewhat similar in point of shape to Miss Blair's central one—*i.e.*, a March stand with an additional tall vase rising from the centre. The flowers were arranged somewhat in the same way as the other, though not quite so overcrowded. There were eight flat glass baskets with glass handles, containing *Roses*, *Geraniums*, and other flowers, and eight tall glasses filled with Grasses. These were arranged four-and-four—*i.e.*, four flat and four tall alternately round each side-centre. The napkins were arranged very tastefully to represent Water Lilies or Lotus, with a buttonhole bouquet in a small glass in the centre of each. When all the small glasses, fourteen in number, the baskets eight, tall glasses with Grasses eight, segmental glasses eight, centre vase eight, and two side vases six, come to be reckoned up, there were according to our computation fifty-two glasses or vases of flowers to be arranged. The fruit was good. Top and bottom, Melon and Pine, two; White and Black Grapes, two; Strawberries, two; Nectarines, two; one Cherry, one Orange, and a Peach in the centre of each of the small vases, supported by the boy Cupids. The table was no doubt on the whole overdone and crowded, though in many respects meritorious, especially in napkins.

The fourth we come to, the fourth prize, was exhibited by Mr. Cypher, of Queen's Road Nurseries, Cheltenham, who, if our memory does not deceive us, easily carried off the prize at Birmingham, and must have done so here, if some evil fate had had not made him put up some extraordinary napkins, looking rather like sugared sponge cakes decorated with louse flowers. If these could have been removed the rest of the decorations were very good; indeed, we have hardly ever seen three better centre vases than those which he showed here. The centre was composed of three tiers of glasses, the base a flat glass but elevated about 4 or 5 inches from the table, standing on a mirror with segments of glass surrounding it. The base was beautifully arranged with a fringe of Ferns drooping gracefully so as to reflect their fronds from the mirror. The flowers were *Ixoras Colci* and *Javanica*, *Eucharis amazonica*, *Roses*, *Dipladenia amabilis*, *Allamanda grandiflora*, with Fern, and *Anthelia gracilis*, having sprays of *Cyperas alternifolius* rising out of it, veiling without hiding the flowers. The next tier of flowers had *Phalænopsis grandiflora*, *Justicia*, *Ixora*, and other flowers mixed with Quaking Grass, and the top was tastefully arranged

with *Paneratium*, *Gloriosa Plantæ*, *Spirea japonica*, and Ferns. The two side centres were somewhat similar, but smaller and not so tall. The flowers in each were very choice, and, though they were not crowded, maidenhair being used more than the Quaking Grass, the upper vases having rich sprays of *Orchidium flexuosum*. There were four oblong vases arranged at each end in the shape of raised glasses, with a taller one emerging from them. These had flat segmental glasses surrounding them, set in the form of a double S, having a fruit dish in the centre. These glasses were filled with choice flowers, but rather overfilled, and the segments were overdone. The fruit, which was decorated with loose flowers and Ferns, was good. Top and bottom Pine and Melon, two Grapes—*i.e.*, black and white, Peaches, Oranges, Figs, two Strawberries, and three Nectarines. The napkins we have already alluded to upon. We could not help regretting that owing to these napkins and also a redundancy of flowers, Mr. Cypher did not gain the first prize which his centre vases richly deserved.

The other exhibit of Mrs. Hick, Milsom Street, Bath, we have already alluded to. There were three similar glass vases differing only in size, made of silvered glass, with a large, light, ruby-coloured ball on which they stood; then stood a large silvered mirror in the form of three circles, connected together with longer pieces, on which were long glass prisms filled with flowers, the circular glass mirrors having imitation glass Water Lilies. The vases had heavy glass balls depending from the upper rim. The flowers in these though good were heavily arranged. There were good flat glasses in which the buttonhole bouquets were placed, and the water carafes which we have already alluded to were good, but, on the whole, we should say the table arrangements were of the shop, shabby.

We may remark, in conclusion, that the tables for fourteen were far too small and too narrow, giving those who wished to decorate highly too small a space, and not sufficient scope for their inventive powers. It was this, no doubt, that led the Judges to give the first prize to one essentially poor and weak. In fact we may conclude that, with the exception of Mr. Cypher's three vases and some of his other decorations, the Bath Exhibition of dinner-table decorations somewhat taught us what to avoid, and we hope that another time the happy mean may be reached between under-paucity and over-decoration; the one tending to poverty and meagreness, the other to an overcrowding which is wearisome to the eye.

Our remarks have taken more space than we had anticipated, and we will pass over the single vases, hand bouquets, and other decorations, to which we may, perhaps, be induced to allude at another time. We intend also, in another notice, to call attention to some of the leading exhibits in the horticultural implement department, though our notes, which we published last year of the boilers and greenhouses at Birmingham, were so full as to preclude the necessity for any lengthened observations this time, as so many of the exhibits were in many respects the same.

CRYSTAL PALACE ROSE SHOW.

JUNE 28TH.

The great Rose Show which is yearly held at the Crystal Palace always attracts thousands of visitors, all of whom appear to be lovers of the Rose, and numbers of them are rosarians. This year the arrangement of the tables was more pleasing than usual, the flat appearance which long rows of stands of cut blooms are wont to present being relieved by the introduction of a variety of plants; indeed, this almost became a necessity owing to several exhibitors, from various causes, not having come forward—a circumstance which must ever interfere with any predetermined plan.

In the nurseryman's class for seventy-two single trusses Messrs. Paul & Son, of Cheshunt, were first with splendid examples of *Barones Rothschild*, *Olivier De-Juanne*, *Miss Poole*, *Général Jacqueminot*, *Madame Boll*, *Mme. Baumann*, *De-Vienne Lamy*, *Aurore Boréale*, *François Louvat*, *Madame Vidot*, *Abel Grand*, *President*, *Gloire de Dijon*, *Camille Bonnard*, *John Hopper*, *Borce Vernet*, *Exposition de Brice*, *Mlle. Eugénie Verdier*, extremely beautiful, *Xavier Olibo*, very fine, *W. Wilson Saunders* (new), *Rev. St. Reynolds Hole*, *Comtesse d'Oxford*, *André Dumand*, *Christine Nilsson*, *Duke of Edinburgh*, *Monsieur Noman*, *Madame Willencoz*, *Ferdinand de Lesseps*, *Edward Morren*, *Louis Van Houtte*, *Lord Macaulay*, and *Marquise de Mortemart*. In the second prize stand, that shown by Mr. J. Cranston, King's Acre, Hereford, the trusses were also of high merit, particularly *Edward Morren*, *Dupuy-Jamain*, *Etienne Levet*, very bright; *Dr. Andry*, *Impératrice Charlotte*, with a fine glow in the centre; *Elic Morel*, *Marquise de Castellane*, *Victor Verdier*, *Prince Camille de Rohan*, *Marguerite de St. Amand*, *La Esmeralda*, *Mons. Noman*; a seedling of the *Madame Moreau* form, but crimson; *Duke of Edinburgh*, *Comtesse d'Oxford*, very fine; *Marquise de Gabot*, *John Hopper*, *La France*, and *Madame Entabé*. Third came Messrs. Mitchell & Sons, Pittdown, with *Barones Rothschild*, *Ferdinand de Lesseps*,

Charles Lefebvre, Triomphe de Rennes, Anna de Diesbach, Madame Lacharme, Comtesse d'Oxford, Henri Ledechaux, Louise de Savoie, Napoleon III., Horace Vernet, Adam, Duke of Edinburgh, splendid; Souvenir de Charles Montault, Richard Wallace, Souvenir d'Elise, and Edward Morren. Mr. Turner, of Slough, took the fourth prize.

The next class, that for forty-eight varieties, three trusses, is always very effective, and so it was on this occasion. Messrs. Paul & Son were again first; Mr. Keynes, of Salisbury, second; and the remaining prizes went to Mr. Cranston, Mr. Turner, and Messrs. Mitchell. Among the varieties best represented were Victor Verdier, Duke of Edinburgh, Louisa Wood, Alba rosea, Marquise de Castellane, Maréchal Niel, John Hopper, Edward Morren, Devonensis, Comtesse d'Oxford, Mdle. Eugénie Verdier, Xavier Olibo, Louis Van Houtte, La France, Catherine Mermet, Prince Camille de Rohan, André Dunand, Marquise de Gibot, Marie Baumann, Lyonnais, Baroness Rothschild, Ferdinand de Lesseps, Dupuy-Jamain, and Triomphe de Rennes.

For twenty-four trebles the honours went to Mr. Cranston, Messrs. Paul & Son, Mr. Keynes, and Mr. Turner; and for the same number of single blooms to Mr. Walters, Mount Radford, Exeter; Mr. Cooling, Bath; Mr. Lee, Lyonslall, Herefordshire; and Mr. Parker, Victoria Nursery, Rugby.

The amateurs' classes were unusually good as regards quality, though the number of competitors was not so great as generally the case at this Show. R. N. G. Baker, Esq., of Heavitree, Devon, who has been successful at the shows of previous years, again took the lead, sweeping off the first prizes for forty-eight, thirty-six, and twenty-four, also an equal first for twelve trusses of any single variety, with stands in which were superb examples of Xavier Olibo, Comtesse d'Oxford, Exposition de Brie, Marquise de Mortemart, Duke of Edinburgh, Maréchal Niel, Louis Van Houtte, Annie Laxton, Marguerite de St. Amant, Louisa Wood, Camille Bernardin, Baroness Rothschild, Marie Baumann, Mdle. Louise Uxkull, John Hopper, François Louvat, Alfred Colomb, and Duke of Edinburgh. Mr. W. Farren, Crescent, Colbridge; the Rev. J. B. Cunn; Mr. Davies, Wilton, Salisbury; and Mr. Ingle, gardener to Mrs. Round, Colchester, took the remaining prizes for forty-eights with excellent trusses.

For thirty-six trusses the Revs. G. Arkwright and J. B. Cunn came in second and third, with Mr. J. Davies fourth. The principal prizes for twenty-four and for twelve trusses went to Messrs. Prince, Ingle, Bennett, J. L. Curtis, Rev. A. Cheales, and W. Soder.

In the open class for twelve trusses of any new Rose of 1872, Messrs. Paul & Son were first with Annie Laxton, bright rose; Messrs. Curtis & Co., Devon Rosery, Torquay, second with Bessie Johnson, large, bluish, a very pretty and fragrant Rose, which was certificated last year. Messrs. Curtis also staged a fine twenty-four of the same variety, but, unfortunately, they were wrongly entered.

In collections of twenty-four new Roses of 1871 and 1872, the prizetakers were Messrs. Paul & Son, Cranston, and Turner. The most conspicuous for quality were Madame Lacharme, white; Lyonnais, Mrs. Veitch, W. Wilson Saunders, President Thiers, Etienne Levet, Auguste Rigotard, S. Reynolds Hole, Bessie Johnson, Richard Wallace, Madame George Schwartz, and André Dunand.

For twelve blooms of any single variety of Rose, equal first prizes were awarded to Mr. R. N. G. Baker and the Rev. G. Arkwright; to the former for Baroness Rothschild, to the latter for Souvenir d'un Ami, both very fine. Mr. Walters had a second prize, and equal thirds went to the Rev. J. B. Cunn and Messrs. Paul for Marie Baumann and Baroness Rothschild.

The best collection of yellow Roses was that shown by R. Webb, Esq., of Calcot, who had, among others, fine blooms of Maréchal Niel, as well as the double Persian. The other prizetakers were Mr. F. May, Braintree, and Mr. Quennell, Brentwood.

Vases and épergnes of Roses arranged for effect were successfully shown by Miss A. Hyder, Messrs. Soder, Rose, and others; Fern cases by Messrs. Dick Radcliffe & Co., and Mr. Jones, Epsom; and there was a host of table decorations, in which Mr. Buster, Mr. T. Wilkinson, and Miss Hudson took the lead. Messrs. Paul exhibited a fine group of Roses in pots; Messrs. Downe, miscellaneous groups; Mr. Turner, Pinks; Mr. Parker, blooms of Paeonies; and the Rev. H. H. Dombain, Ranunculuses.

GREENHOUSE GLAZING.

I MET with a method of glazing the other day which was new to me, as it may be to many of your subscribers, and as I was assured it was perfectly successful, I send you a short account of it. I could see for myself that it looked well, and was a great saving in putty.

The rafter and rabbit are made as usual, but the glass is cut slightly narrower, leaving nearly one-eighth of an inch play on

each side. The putty is put on the rafter as usual, and the glass pressed down, and on the putty rising on each side, a knife is passed along the face of the glass, removing the whole of the putty which bulges up. The rafter then receives three coats

of paint, allowing the paint to come slightly on to the glass. The effect of this method is that there is no putty to crack away from the rafter, as usually happens; there is only a quarter of the putty used, and when kept painted no water gets in and rots the wood. In the old method you found the putty cracking and coming away in long strips, and when once it had begun to crack there was no use painting, as the putty came away paint and all. The panes of glass are kept in their place by a small half-inch tack at the upper corner.—J. P., of York.

NOTES AND GLEANINGS.

THE following are THE RESULTS OF THE ROYAL HORTICULTURAL SOCIETY'S SHOW AT BATH, as far as can be ascertained at present. The number of visitors and the receipts at the gates were on

	Visitors.	Receipts at the Gates.
		£ s. d.
June 24th	2530	69 17 6
" 25th	10,238	509 16 11
" 26th	20,100	867 16 2

Total	54,011	£2154 1 5

In addition there was a considerable sum derived from the sale of tickets before the opening day, which will greatly swell the amount, besides a sum of £16 19s. 6d. derived from Bath chairs.

— In the *Yorkshire Gazette* we see it is stated that the POTATO DISEASE is reported to have appeared in various places in North Yorkshire. The early American varieties seem mostly affected.

IMPORTS OF POTATOES AND GUANO.—The importation of Potatoes still increases. In the last month the value was £232,396, and in five months £1,546,426, and in the same period last year £145,709. In the last five months the increase of guano imported was considerable compared with the same period in the preceding year. In 1872 the amount was £315,652, and this year £712,500.

GARDENING IN THE WEST.*—No. 4.

WARMINSTER.

FROM Trowbridge to Warminster is a short run by rail; and at Warminster the great attraction is the nursery of Mr. George Wheeler, one of the best in the west of England, as it is also one of the most interesting. All nurseries are interesting more or less to someone, however small and however special the cultivation may be; but the nursery of Mr. Wheeler is one which must be interesting to everybody, as it has preserved all the characteristics of the olden time while it has kept well in front with the present. Here we meet with every novelty worth cultivating, and here, too, we find such a collection of herbaceous plants and ornamental trees and shrubs as would amaze and puzzle the modern gardener—even modern nurserymen would be lost here. It is quite refreshing to spend even one day in this nursery, and especially if you are fortunate enough to have Mr. Wheeler himself as your companion. Though eighty-two years of age he possesses all the energy and activity of mind he ever had, and there is not a plant or tree in his vast collection of which he cannot readily tell the name. May his bow long abide in strength! This nursery consists of several

Our view of Wood Ashton in last week's number was from a photograph taken by Mr. Wilkinson, of Trowbridge. Our view of the entrance to the Victoria Park, Bath, was from a photograph by Messrs. Dutton, the eminent photographers of Kenrietta Villas, Bath.

detached portions, necessitated from the difficulty of securing a sufficient area in a ring fence. In all it measures over forty acres. In an establishment of this extent we expect to find a great deal. There is, of course, the ordinary nursery stock of forest trees, hedge plants, and such shrubs and flowering trees as are usually planted for the ornamentation of grounds; but besides these there is a very full collection of trees and shrubs such as are used to form arboretums, and what is more surprising in the present day, Mr. Wheeler has preserved and added to his long-existing collection of herbaceous plants, which cannot be less in number than two thousand species and varieties. These he continues to cultivate with all his wonted assiduity—not starved things in No. 60-pots, but large masses planted out in the open borders after the fashion of botanical collections, whereby the habit and full character of the plants can be easily judged of. The glass houses contain the ordinary stove and greenhouse plants, but there is a specialty in the *Calcarias* grown by Mr. Wheeler which must be seen to be appreciated. The strain he has succeeded in obtaining is a very dwarf-habited plant not more than 6 to 9 inches high, producing a mass of flowers like a head of Cauliflower, remarkable in the size of the flowers, in their colours, and markings. This is the finest strain of *Calcarias* we have ever seen. We cannot undertake to mention, far less to describe, all we saw at Mr. Wheeler's; but we can promise those who have a love for plants, and who are not "bedders-out" only, if they pay a visit to Warminster and call on Mr. Wheeler they will be amply repaid, however far they may have journeyed.

There is a good healthy gardening spirit of emulation about Warminster. Roses and Rhododendrons are here in the ascendant, and here, too, resides our excellent friend and correspondent, Mr. Hinton, who, while he is not engaged in ministering to the physical and sanitary well-being of the population, may be found tending his choice collection of Roses, and otherwise storing his mind with gardening lore to be dispersed for the benefit of all living through the pages of our Journal.

The private garden of Mr. Smith, a resident in the town, is well worth seeing at this season of the year. In acreage it is not extensive, but is of good size for a villa garden. The great feature here is a bank of Rhododendrons and Azaleas, which even Knaphill and Bagshot could not surpass. There are also some good specimens of Conifers and other ornamental trees, and especially a handsome Purple Beech. Mr. Smith's specialty is Roses, and these he cultivates to perfection. Such flowers of *Maréchal Niel* must be seen and not described. No wonder that in the "election of Roses" so skilfully conducted by Mr. Hinton, Mr. Smith should have placed the *Maréchal* at the head of the poll, for we never saw such Roses. Mr. Scott has also a good little garden upon which he bestows great care, and in which, besides a nice collection of stove and greenhouse plants, he cultivates very successfully a choice collection of Roses.

HEYTESBURY.

While at Warminster we took the opportunity of running down to Heytesbury, a quiet, secluded, pretty, little village, nestling under one of the southern slopes of Salisbury Plain, and a quondam borough disfranchised at the first Reform Bill. Here, at Heytesbury House, is the residence of Lord Heytesbury, situated in a beautifully wooded park, which, like that at Rood Ashton and other parks in the county, would be improved if some of the trees were thinned-out, and those left were thrown more into groups. The fact is that some of these parks assume more the aspect of forests than parks, through a judicious arrangement of the trees having been unattended to. At Heytesbury there is ample material to work upon, and beautiful as the park is, a judicious thinning would add still more to its beauty.

Gardening at Heytesbury is at present in a transition state. The old garden, which was an extensive walled-in space, was situated on the north side of the house; but the present lord being desirous of including this in the park, and removing the garden farther from the house, a new one is in the course of formation on the opposite side of the turnpike road which passes through the estate from Warminster to Salisbury, and as yet little progress has been made with it. We have therefore little to say about the gardening of Heytesbury, which has for the last thirty-eight years been well presided over by Mr. Rose.

Returning to Warminster by rail, the next attraction which commands attention is

LONGLEAT.

Longleat, or Langlate, is the princely residence of the Marquis

of Bath. It is in the parish of Horningsham, and is the domain once belonging to a St. Augustine Priory, dedicated to St. Radegund. The Priory was dissolved by Henry VIII., and the estate granted to John Horsey, and in the year following he conveyed it to Sir John Thynne, ancestor of the family whose property it has continued. He built Longleat, beginning it in 1567, and nearly finishing it in 1580, in which year he died. Details of all he accomplished are in Hoare's "Modern Wiltshire," but we must only record here that "he made a garden and orchard where part of the present garden is, and planted an orchard and Hop yard where the Chestnut grove now is."

It is said that the drawings of the mansion were furnished by an Italian architect, and that John de Padua, "Devisor of his Majesty's buildings" to Henry VIII., was Clerk of the Works. The Elm avenue to Frome was formed by one of his successors, murdered in 1682, but the mansion was completed by his successor. The planting of the park was confided to "Capability Brown," and 50,000 trees are said to have been planted annually during several years.

It is five miles from Warminster, and about the same distance from Frome. Approaching it from the former, the park gates are reached less than two miles from the town, and from the gates to the house is rather over three miles, through woods of fine timber, the road winding and undulating so as to command the splendid views which, from the elevated position of this part of the park, are to be seen from various points. This road is wide with broad margins of grass on either side, from which green glades occasionally penetrate the woods, relieving the dull monotony of the continuous margin of trees. If a little more were done in this way, the approach on the Warminster side might be very much improved. Here and there, and at certain distances along the route, large masses of Rhododendron ponticum have been planted. These extend far away among the timber, and on the occasion of our visit they were in their greatest beauty. Lord Bath appears to take much pleasure in this mode of decorative planting, to which are added at intervals single specimens of the most ornamental Conifers. Within a mile of the house the road begins to descend abruptly till it enters a wide richly-timbered valley intersected by a stream, on the farther side of which the house is seen in all its stately grandeur. As we approach it we find there are no dressed grounds to pass through in order to reach the entrance front, for the park comes close up to the house, and the road, which from its appearance and the freedom with which Lord Bath permits the public to use it, is more like a highway. And here we take this opportunity of testifying to the self-denying liberality of this estimable nobleman; possessed as he is of one of those grand ancestral domains of which Great Britain only can boast, and which he has a perfect right to reserve to his exclusive private use, he nevertheless throws the roads and the park open for the public benefit, that they may roam about and enjoy the amenities of the locality as much as he does himself. Some, we were told, not unfrequently have the bad taste to picnic under the trees immediately in front of the principal entrance, and such is the courteous bearing of the family towards these intruders that they are never interfered with. In short, the inhabitants of Frome and Warminster and the surrounding country have this magnificent park kept up for the public benefit, and we trust they duly appreciate the boon.

Having now met Mr. Taylor, the competent head of the gardening department, we were conducted over the principal parts of the grounds.

When we visited Longleat thirty years ago, there was on the north side of the house a flower garden of elaborate pattern, designed by the then Marchioness of Bath. It might have been regarded as the forerunner of all the modern styles of flower gardening, and it showed an originality of invention and a skill of adaptation which the garden-designers of our own day have not surpassed. This, however, has been cleared away, and a new arrangement has been adopted, which is being carried out by Mr. Gibson, jun., in conformity with the views of the Marquis, who is taking great personal interest in the new works. Other great changes are being made in this part of the grounds, which when completed will be highly ornamental. Bounding the flower garden on the north is an old orangery of the original type, a substantial structure with a slated roof and windows only in front, such as were erected from the beginning to the middle of the last century. In this there are some very large Camellias of the older time which

are the pictures of rude health, and being annually covered with a profusion of bloom seem to luxuriate in their location. The light being only on one side of the trees—for trees they are—have grown all in that direction. They are planted in slate tubs, the soil being loam and peat. It is a pity that a house of this size and substantial character should not be made more useful by having the present roof removed and a glazed one substituted. It might in this way be transformed into a handsome conservatory, for which its ample dimensions and sufficient height fully qualify it.

Between this flower garden and the water is a lawn, on which are planted some fine specimens of ornamental trees. Among these our attention was attracted to noble Tulip Trees, Cut-leaved Beech, *Robinia viscosa*, *Ptelea trifoliata*, and other species, while at some distance from these there is perhaps as fine a

specimen of *Abies Canadensis* as is to be found in the country. We measured it, and found it was 37 yards in circumference, forming a perfectly round ball.

The kitchen gardens are a mile from the house, and the path leading to them is through the woods, from which picturesque peeps of the valley and the richly wooded park beyond are here and there obtained. Since Mr. Taylor was appointed to the management of the gardens great alterations and improvements have been made in this part of the grounds. At intervals along the course of this walk the original underwood has been cleared and the space occupied by specimen Conifers and other ornamental trees, while in places where the ground is suitable wide clearings are made, and deep glades which lose themselves in the shady vegetation make a pleasing variety in the scenery. In these alterations we were told the Marquis takes a lively in-

LONGLEAT.

terest, and the effective manner in which they are carried out testify to his lordship's good taste and appreciation of artistic design. As we near the kitchen garden these clearings become more extensive, and between the woods and the entrance the walk leads through an extensive lawn, planted with fine specimens of ornamental trees, some of which are of great age and size, and among them a *Salisburia adiantifolia* 65 feet high. On the way from the house through the woods are some fine trees of Purple Beech, and a noble specimen of Tulip Tree 100 feet high.

The kitchen garden within the walls seems larger than it really is, Mr. Taylor having given the extent as four acres and a half. The glass is extensive, and is devoted to plant and fruit-growing, much in the proportions that are expected in an establishment of the size of Longleat. For internal decoration Mr. Taylor sends in fourteen hand-barrowloads of plants at a time, from which one may gather to what extent plants are grown, and they are well grown, as everything else in the garden is. In the range of old houses we saw one division of it, 40 feet long, entirely filled with an old Vine in the best of health. The new houses which have been built in the upper garden are very commodious and useful; they consist of three ranges standing parallel to each other, each of which is 35 yards long by 18 feet wide. Though skilful in all the branches of gardening, Mr. Taylor is especially so as a fruit-grower; his Cucumbers, Melons, and Vines are a sight worth seeing. Like

a judicious man, he never grows more than one sort of Cucumber and Melon, and consequently he has always a pure stock of each, instead of the mongrel varieties which those must necessarily have who grow more than one variety. These he grows trained under the glass like Vines; and like Vines they are in more than one respect, for the strength and vigour of the stems and branches are marvellous, though each plant has not a bushel of soil to grow in. The Melon to which Mr. Taylor gives the preference is Cashmere, a valuable old variety, the only defect of which is its liability to crack in ripening. This he obviates by strangling the stalk of the fruit and checking the excessive flow of sap.

The great feature in the garden at Longleat is the large viney which has been recently erected. It is 216 feet long by 30 feet wide, span-roofed with a lantern ridge, and 18 feet from the floor to the ridge. It is a fine structure, and, with the exception of the large conservatory at Chiswick, we should suppose this is the finest viney in the kingdom. The Vines are all planted inside, and we never saw plants growing with greater luxuriance. The Vines are yet young and have not produced fruit, but we expect to hear of their doings some day. This house, the design of Mr. Taylor and built under his direction, is worthy of his ability; and constructed as it is according to his ideas of the requirements of good Vine-growing, we can see already in the state of the Vines that his conception has been a true one.

There are very many things of which we could have written to be seen in this fine place, but our space is limited. We hope to have future opportunities of returning to the subject, and every year will add to the interest of it; for the Marquis of Bath being himself possessed of great taste, we have no doubt that, under his direction and the practical experience of Mr. Taylor, Longleat will become one of the most interesting as it is one of the grandest places in the kingdom.

A CENTURY OF ORCHIDS FOR AMATEUR GROWERS.—No. 12.

ONCIDIUM.

An extensive genus, the species of which, like the *Odontoglossums*, are found luxuriating in high mountain regions of the western hemisphere, although unlike the last-named genus, they are not exclusively mountain plants, for many of them are found in the islands of the West Indies, and at low elevations on the mainland. The following, however, will thrive well under cool treatment:—

O. BIPOLOM MANS.—This beautiful plant is a wonderfully profuse bloomer. It is a compact, free-growing plant. The flowers are large and very bright yellow. It blooms during early summer. This variety succeeds best when grown upon a block of wood or in a basket. Native of Monte Video.

O. FLEXUOSUM.—In the days when so many new kinds are being introduced, many of my readers who are already advanced in Orchid culture may smile at seeing such an ancient recommended, nevertheless I confidently recommend it to general notice. It grows freely, produces its brilliant yellow flowers in great abundance, and is simply invaluable for setting for dressing vases, &c. I have heard it makes a fine ornament for embellishing a lady's hair, but I do not think yellow should be used for such a purpose if seen by daylight, whilst by gas-light yellows always appear white. It should be grown in a pot. Native of Brazil.

O. INCURVUM. A very elegant and distinct plant, added to which it blooms from the month of August into midwinter. Pot-culture suits it best, as this species is a somewhat robust grower. The flower-spikes are much branched, and about 2 feet high; flowers very numerous; sepals and petals rosy pink, freckled towards the ends with white dots; lip white in front, rosy pink at the base; crest yellow. Native of Mexico.

O. LEXOCURVUM.—This is a very fine, robust old plant, discarded by many cultivators, but really a beautiful subject when well grown. It produces much-branched spikes some 8 or 10 feet long, clothed with numberless flowers; sepals and petals yellowish green, with a large pure white lip. It blooms nearly all the year round. Native of Mexico.

O. PSEUDOCALYPTUM MANS. Like the preceding, this is an old Orchid, but a valuable one where cut flowers are in request. It produces very long branched spikes of flowers, which are bright yellow, barred with brown. It blooms at various times, but usually about the end of spring or the beginning of sum-

mer, and the flowers last a month or five weeks in full beauty. Native of Mexico.

O. PHALANOPSIS.—This beautiful species is dwarf and compact in habit. The scape usually bears some five or six flowers; the sepals and petals are creamy white, barred and spotted with reddish violet; lip large, of the same colour as the perianth, and furnished in addition with a beautiful golden yellow crest. It likes an abundance of water, and should be grown in a pot, but a very little peat and sphagnum must be placed over its roots. Native of the high mountain regions of Peru.

CATTLEYA CITRINA.—This has always appeared to me a most interesting plant, and I would advise all amateurs to add it to their collections. Many Orchid-cultivators do not succeed with this species, but if two rules be observed little difficulty will be found. First, the plant must be grown upon a block

of wood, and always hung with the leaves pointing downwards; next it must be grown in the cool house with *Odontoglossums*, and should never be subjected to the drying system. The plant has small, oval, pseudo-bulbs, which, together with the leaves, are glaucous green; the flowers are usually solitary, sometimes, however, they are produced in pairs; they are very large for the size of the plant, thick, and waxy-looking, whilst the colour is rich deep yellow. The blooms last about a fortnight in perfection, and are very sweet-scented. Native of Mexico.

PHAIUS GRANDIFOLIUS.—In this plant we have a very old inhabitant of our gardens; it is a terrestrial plant, growing about 3 feet high. The leaves are broad, plicate, and dark green; flower-spike longer than the leaves, erect, and many-flowered; the blooms are large, and curiously mottled with reddish brown and white. They are produced early in spring, and remain long in full beauty. It comes from China, where it is a cultivated plant. — **ERBERTO CRUDE.**

Oncidium incurvum (Bot. Mag.).

HEREFORDSHIRE (WEST OF ENGLAND) ROSE SHOW.—In our advertising columns will be found a notice of this Show, which will be held in the Shire Hall, Hereford, on Tuesday, July 8th. If the sample of Roses shown by Mr. J. Cranston at Bath on

June 21th and 26th may be taken as a type of what Herefordshire can produce this year, the Show should be an exceptionally good one and a treat to all rosarians. It certainly deserves all encouragement, as it is one of the few instances where a district show has been carried on with merely the Rose (the queen of flowers) as the object of attraction. We have rarely hitherto seen better Roses exhibited by amateurs than those which on different occasions have been shown in the Shire Hall at Hereford; and we especially noticed at the Rose Show on the third day of the Royal Horticultural Society's Exhibition at Bath, that the west-of-England amateurs—Mr. Canon, Mr. Baker, Mr. Scott, and others, carried all before them. We prophesy, therefore, that there will be a more than ordinarily good show.

BIRMINGHAM ROSE SHOW.—I know that a great many of those who have hitherto supported our Show will not do so again,

unless the Committee go back to the old times. The Show must be kept special, or it will utterly collapse, and more common sense must be exercised in selecting the date. An exhibition of Roses for the midlands in the middle of June is simply an impossibility; no Rose Show can or should be held here earlier than the first week of July. Until this year our Rose Show has been equal to anything achieved even in London. I sincerely trust that the Committee will seriously consider its present condition and quality, and do something to restore it to its old prestige.—Z. O., Birmingham.

WORK FOR THE WEEK.

KITCHEN GARDEN.

IMMEDIATELY a crop is done with, either remove or dig it in. In either case sprinkle the ground with lime to destroy slugs, but more abundantly in the latter than in the former case. In all cases of earthing-up crops in dry weather give them a good soaking with water previously. A few Mazagan Beans may yet be put in, which will produce late in the season if the weather prove favourable. *Cape Broccoli* and Grange's may now be planted where the early Peas have been removed. The main crop of the other sorts must be got-in as early as possible. If the weather continue dry they will require an abundant supply of water. Sow a little more *Cabbage* seed immediately, if the sowing we recommended last month has failed. Another sowing of *Chervil* should now be made for succession. Put in a few cuttings of *Cucumbers*. Sow a little seed so as to have a few plants to plant-out for a succession till Christmas. Continue to pay every attention to those in frames; they must have a liberal supply of water twice a-week, and should be sprinkled every afternoon. Continue to plant-out a few *Endive* about once a fortnight to keep up a succession; another sowing should be made. The last principal sowing of *Dwarf Kidney Beans* should now be made. Earth-up the advancing crops. Those in flower will be greatly benefited by a good watering. Those *Leeks* sown in drills should be thinned to a foot apart in rich ground; the thinnings will do to plant out. Make a sowing of *Parsley* so as to get strong plants by the winter. Earth-up and stick the advancing crops of *Peas*, water those that are in bearing. A few more may yet be sown, which will come into bearing if the autumn is favourable. Make a sowing of the various sorts of *Radishes*. The Turnip-rooted, however, are generally preferred at this season. *Vegetable Marrow* plants will require a pretty liberal supply of water during the continuance of dry weather. Stop the main shoots to cause them to throw out laterals.

FRUIT GARDEN.

Grape Vines against walls now require unremitting attention. Train up young shoots from the lower part of the wall for bearing next year. Stop the bearing shoots at two joints above the fruit; remove all useless and superfluous shoots. Wash wall trees to free them from dirt and insects. Thin the summer shoots of Gooseberries and Currants. Protect fruit from birds. Hang up bottles of sugar and beer to entice and catch wasps. Encourage the growth of Strawberry runners. The packing of fruit to be sent to a distance is a very important matter, and one that is deserving of more attention than is usually paid to it; at least, if I may judge from what I have lately seen, I do not think it necessary to pack Grapes in bran, or Peaches in cotton, to insure their safe carriage. The former can scarcely be freed from the bran, and the cotton sticks to the skin of the latter, which is with difficulty removed. Experience leads me to believe that the best method of packing Grapes is to put a layer of moss or dry short grass at the bottom of a shallow box, which is afterwards covered with a sheet or two of silver paper; a layer of Grapes is then placed in, and over them a few more sheets of paper and a more moss, so as to keep them tightly packed when the cover is on. Peaches and Nectarines should be wrapped up separately in silver paper, and then packed in cotton, moss, or dry short grass. If a box is to take more than one layer, a false bottom should be placed between each one. The usual fault in packing is giving the fruit too much spring. The tighter they can be packed in any soft material without injury to the fruit the less liable are they to sustain injury by carriage. The boxes should afterwards be placed in a hamper, which gives more spring than they otherwise have.

FLOWER GARDEN.

Remove suckers from Roses, and clear the stems of wild shoots. Strong shoots of Chrysanthemums may now be layered in pots to produce dwarf compact bushes. Those in pots may soon receive their final shift. Carnations and Picotees will soon be in bloom; let plants in pots be moved under an awning like that used for Tulips. Here they may be arranged on a raised platform or not, according to taste. Picotees may be grouped on one side and Carnations on the other, taking care that the tallest plants are behind, and at the same time contrasting the colours as much as possible. Pippings may be put in on a slight bed; layering may also now or very soon be pro-

ceeded with. Much of next year's success depends on this matter. All seedlings should be marked, noticing their various properties as to form, colour, substance, &c. Ranunculuses may be taken up as soon as the foliage has turned yellow, for should wet weather ensue they might emit fresh fibres, and if taken up then they are likely to be worthless.

GREENHOUSE AND CONSERVATORY.

There is a scarcity of flowers generally in the conservatory now. The usual routine of training the climbers and keeping the other plants in order, together with neatness, is all that is immediately wanted, but keep a good eye to your winter stock. Camellias that have formed their flower-buds may now be potted; those of them that are to flower early should be kept in-doors all summer, but the spring-flowering ones may be turned out soon. Attend to Violets and Chrysanthemums. The China Rose, called *Cramoie Supérieure*, is the best of them all for winter forcing, and takes the place of the old *Sanguinea* in the bouquets at Christmas. Anne Boleyn Pinks for forcing ought to be now in a forward state, and if they show symptoms of flowering, pinch off the stems as they appear. In short, this is just the time to attend diligently to such plants as will flower from October to May. All but the very best specimens are now removed from the greenhouse; you will have room to introduce annuals, planting three or four of them in large pots; with a little care they will come in useful for the conservatory.

STOVE.

If you imagine that any of your established stove plants will require another shift this summer, let it be done soon, but avoid shifting large specimens so late if you can; rather encourage them with a little liquid manure occasionally. Your young plants may be potted as they require it for the next two months. Do not neglect to make cuttings of *Justicias*, *Clerodendrons*, and such useful plants early in July for flowering next year; these will form beautiful plants before the end of October. *Pentas carnea* belongs to this class; it is a very useful plant in winter, and may be had in flower all the year round. Air, moisture, and cleanliness, as usual, are requisite.

PITS.

For growing a stock of young plants in summer no structures are so good or economical as good pits. Place the pots on a bed of sifted coal ashes, and if you can procure clean moss free from slugs, &c., it is an excellent plan to place a thin layer of it between the pots after it is well damped. You have thus a source of constant moisture, which, passing up among the foliage, is very beneficial to all plants in summer, and they require less shading when they are thus managed. The pits and frames used for propagation must be kept shaded throughout the day; give little or no air; where bell-glasses are used, wipe them occasionally. Cuttings of Roses and many Heaths may now be put in with every prospect of success; shade them and keep them moderately moist. Pay strict attention to young seedling exotics. Continue to put in cuttings of all plants required which can be propagated at this season; pot-off those cuttings that are rooted.—W. KEANE.

DOINGS OF THE LAST WEEK.

No rain, but a week of high winds, which have been very injurious to vegetation by tearing-off and lacerating the leaves of tender plants. Such weather is also injurious in another form, as it brings hordes of aphides into the garden. So much is this the case, that many persons argue for spontaneous generation; of course we believe in no such thing; what we do believe is that certain states of the atmosphere are more favourable to the increase of this pest than others, and the wind carries them hither and thither until they find a suitable breeding-ground. We had some hand-lights filled with plants perfectly free from green fly; they were carefully watched every day, and it was found that this pest was blown on to them very often from some Roses about eighteen paces from the hand-lights—at least there was no other apparent cause of their presence.

KITCHEN GARDEN.

Notwithstanding the dry weather, the *Peas* are doing very well, and are continuing to bear abundantly; it would be as well to note that the best early Pea for flavour is Laxton's Alpha; and the best-looking pod, which fills very early, and is of a very deep green colour, is William I. The later Marrow Peas are coming in; one of the very earliest and best is G. F. Wilson; it is very near to Veitch's Perfection, but comes in much earlier.

Celery.—We have been planting successional crops of *Celery* in trenches not so deep as usual. We have much difficulty to keep *Celery* from rotting in the winter, but we never so careful in earthing-up; whether it is the climate or soil we know not, but all sorts are alike; cocoa-nut fibre refuse was tried, but we did not succeed with this, and only tried it once. Lettuces and other small salads are grown on the ridge between the trenches. After this Cauliflowers will not succeed with us; they become club-rooted, and have never yet been worth the ground and labour bestowed upon them. We beat the gardeners

who have clay soils with early vegetables, but for late summer crops we have no chance against them.

FRUIT AND FORCING HOUSES.

Pine Houses.—Except to attend to ventilation, only one matter requires to be mentioned; it is apparently a small one, but in reality it is not so. Under the back wall is a staging for plants, and occasionally specimens are taken out of the plant stove and placed here, and notwithstanding the utmost precautions being taken to keep them free from mealy bug, this pest has on two occasions appeared on the Pines. As soon as it was observed, the plants infested were taken out and destroyed. We had to adopt the same radical cure on a plant last week. The only way to keep clear of the enemy will be to confine the stove plants in the house devoted to them. On one other occasion we had some trouble with its appearing in the early viney, the bunch or two affected were removed, and the others carefully watched for its re-appearance. This hint may act as a caution to others. There are few plant stoves free from this mealyascal, and when the house is too full of plants it is better to throw them away than it is to risk spreading the enemy in Vine and Pine houses.

Vinerias.—In the early houses little or no attention is required; the houses are looked over once a-week or so, and any decayed berries removed from the bunches. When the berries showed signs of shrivelling we gave the roots a very moderate application of water. In late houses, except damping the borders and paths twice a-day to produce a moist atmosphere, and pinching-back all growing shoots where the houses are already well furnished with leaves, our work for the season is pretty well over until the crops be gathered.

ORCHARD HOUSE.

As there are now plenty of excellent *Strawberries* to be gathered out of doors, there is no need to trouble in watering those in pots, although *British Queen*, *La Constante*, and *Frogmore Late Pine* are just ripe. Owing to a press of other matters the *Strawberries* in pots were not watched so carefully as they ought to have been, and the berries in an early stage of their development were attacked by mildew; the weather being favourable to its spread it increased with singular rapidity. On its first appearance a dusting with sulphur would have arrested its growth, and the warm pipes painted with sulphur would have effectually cleared the plants. This was not done, and the result was that much fine fruit was spoiled. Some of the varieties are much more liable to be attacked than other.—Amateur the most, and *La Constante* the least. A head gardener should be Argus-eyed to notice everything himself. The young gardeners who have the charge of departments ought to be specially watchful for the first appearance of any enemy—insect, fungus, parasite, or otherwise, and lose not an instant in having it conquered.

Peach and Nectarine trees in pots require much attention. We have surface-dressed, and the fresh rootlets are ramifying into the rich material; fresh dressings will be applied as the others disappear. The growing shoots are stopped as often as they require it.

FLOWER GARDEN.

Our garden is not a large one, nor is the accommodation for bedding plants extensive; but if there is one thing in which we take a pride more than another, it is to see the flower-beds well filled early in the season. They are now a mass of bloom, and being filled with continuous-flowering plants they will remain so until the end of the season. Many of the beds had been previously planted with spring-flowering plants, and the way the *Hyacinth* and *Tulip* beds are managed is this: When the bulbs are planted the beds are first deeply trenched and plenty of manure added, so that the ground is in good condition at the time the bedding plants are put out. Instead of lifting the bulbs, the plants are planted amongst them without removing the leaves and stalks. These, as far as our observation has yet gone, afford some slight protection from frost and winds; when they decay they are removed. Next season the same bulbs will give a good display of flowers without being removed, and when they are done flowering will be lifted and planted out in a spare piece of ground, or given away amongst the cottagers. By this plan we only require to purchase imported bulbs once in two years.

We have been cutting the grass edgings, and hoeing and weeding all beds and borders. All Roses over-blow and faded are picked-off, removing the seed-vessels at the same time. All suckers are removed with a sharp spud.—J. DOUGLAS.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Book.—*H. O. T.*—In addition to those you have there are the Rev. S. B. Peck's "Book about Boses," Mr. W. Paul's "Rose Garden," with coloured illustrations, and the Rev. R. W. Thom-son's "Amateur's Rosarium."

ELMS DESTROYED BY SPIDER MITE.—Loosen the bands that have injured the bark, and mix over the wounds a thick mixture of cow dung, clay, and

water. Support each tree by a hoop bound round with straw to prevent the bark being chafed, and have three wires attached on three opposite points of the hoop, and fastened to stakes driven into the ground at about 3 feet from the tree stem.

JAPANESE HONEYSUCKLE (*Alicia*).—It very commonly blooms in England. You are correct in naming *Geraanium lucidum*, but we cannot identify the other from the specimen enclosed.

LIGHT MANURE FOR WINDOW PLANTS (*H. L.*).—Guanoo 1 oz. to the gallon of water, thoroughly dissolved and strained before use, applying it at every alternate watering.

SUPPENDING HARD WATER (*Idem*).—Place it in an open tub or cistern exposed to the sun for a few days, and it will lose much of its hardness.

TRAINING AND PRUNING CLEMATIS STANDESHII (*E. R. O.*).—It may be pegged down so as to form a bed quite as well as *C. Jackmanni*. Both should be pruned early in spring just when the buds are swelling. Cut-out the old, and leave the young shoots of last year.

CACTUS SPECIOSISSIMUS PRUNING (*Fudge*).—We do not see what you want in pruning this plant as you propose. Leave it as it is, and put in heat stakes so as to bring it into form. No pinning is needed beyond cutting out, immediately after flowering, the old stems close to the point whence they proceed. Let the plant grow and flower.

VINE IN GREENHOUSE (*Idem*).—The shoots that come from the bases of the leaves are laterals; they should be repeatedly pinched to one leaf as they grow. Stop the canes when they reach the top of the house. The wires should be 15 inches or 16 inches from the glass, and the Vines ought to be trained in the same way as the runners run. The rods or canes in a greenhouse should be trained 3 feet 6 inches or 4 feet apart, so as not shade the plants too much. One Vine with three canes will be sufficient for your house.

DESTROYING APHIS IN CONSERVATORY (*Stainchly*).—The only means we know, without resorting to fumigation with tobacco, or using tobacco water or other solution likely to cause coloration, is to dust the plants with tobacco powder, but as that has to be syringed off it will leave its mark. Our correspondent has been told that some decoction in which quassia forms a part, has been found useful. We should be obliged by particulars of a solution that will destroy aphid and not discolour the woodwork, &c.

MELONS WITH FRUIT FLOWERS ONLY (*Hard Times*).—Your Melons must be very vigorous, in which state alone we have known them produce female flowers only, or but few males. Could you not bring male flowers from other plants, or those of a neighbour who wish to improve their female flowers? It is not necessary that they should be of the same kind or plant, only it will not do to save seed from them unless they are impregnated with the same kind. We should secure the male flowers from some friend or neighbour's plant to insure fertilisation. Your treatment, so far as we have it explained to us, is right. Give a little more air and keep rather dry whilst the fruit is setting.

BARREN STRAWBERRY PLANTS (*E. C. H.*).—We do not know of any means of distinguishing the barren from the fertile plants. The method we adopt is to take runners from plants that have fruited, and from none other. We have not any barren plants, but some go blind. Why not remove the barren plants now? They only impoverish the ground, and the unfruitful are grosser feeders than the fruitful.

PEACH TREES OUT OF DOORS SHEDDING LEAVES (*T. J.*).—We think the leaves are shed from the cold and the effects of an attack of insects. The mulching with half-rotten manure and giving a good watering will do good if your trees are not vigorous. If they are very vigorous the manure would be injurious. The mulching of straw only prevents evaporation from the soil, which in seasons like the present is not great.

CAULIFLOWERS DESTROYED BY GRUBS (*Euphorbia*).—There is no specific against club or ambury. Probably the best remedy is to dress with gas-lime at the rate of twelve bushels per acre, pointing it in with a fork before planting. A good dressing of soot, also lime and salt, is good. Of the last use twenty bushels per acre, and of soot enough to make the surface quite black, pointing in before planting. Apply the salt as a dressing to the surface. Before planting dip the stems and roots in a composition formed of soot, lime, and cowdung in equal parts brought to the consistency of thin paint. The best preventive is to plant in ground not recently cropped with any of the Cabbage tribe.

BUSKIDEE GRAPE (*J. Lovell*).—We remember the Grape well—the *Hubscher unguis*. It is our Black Muscadine, and may be obtained in most English nurseries. We will keep in mind your request about the back volumes.

GRAPES FAILING WHEN COLORING (*C. F.*).—Your account is not very clear, but we think your Grapes must be badly mildewed. Such attacks are very rapid and often unexpected, and the remedy or prevention difficult. We have checked the evil at times by sulphur applied to the vines on a dull day, a brisk fire being kept up both then and at night, so as to fill the house with a strong sulphurous vapour, but not by any means to burn the sulphur, as that destroys the foliage. Even the milder emanations from dry sulphur alone plentifully scattered over the house will sometimes check this pest. In dull seasons like the present it is advisable to sulphur as a precautionary measure, as it unfortunately sometimes happens that the too liberal use of sulphur on pipes or lines, heated so as to give off a strong vapour unpleasant to breathe, is hurtful to the stalks that support the berries, and slauking takes place. Considerable caution is required in using sulphur, but if the case is very bad it is indispensable, and we know of no other remedy. It may be some consolation for you to know that mildew has been very prevalent this season, and many promising crops of Grapes have fallen a prey to it. Of course we know that mildew is a fungus which attacks the berry, generally on one side; and the part that is attacked is so injured that its further growth is prevented and the berry continuing to swell, the skin, not yielding to the expansion, cracks, and decay sets in. If, therefore, you have not already tried sulphur, do so at once. It may, perhaps, be of some service; but we fear if the disease has run some days it will be of little avail.

SHAWBILLS (*Sudworth*).—The varieties are so numerous, so nearly alike, and are so liable to damage during their carriage, that we cannot undertake to name them.

ESPALEER PEAR AND PLUM TREES NOT FRUITFUL (*Bird-song*).—We believe the crops are only indifferent in the districts where these fruits are extensively grown to supply the London and other markets, although Apples and the small fruits are plentiful enough; but if it has always been so in former years, then there must be something wrong. We have more faith in the season and situation influencing the crop than any particular mode of pruning either the tops or roots; but the latter operation would seem the more necessary in your case, as you say the trees make long rampant shoots which

are destitute of fruit buds. It is not of much use to shorten them at present, as doing so would cause the production of a host of laterals. But some time in July, when the shoots are partially ripened at their base, they may be stopped, or rather one-half their length should be cut away, first tying in what new wood is wanted. When the shoots are cut off, they should be dried in a hot air stove, or in a dry place, and then be used for grafting. It may be still further shortened, and in the winter the trees may be stopped. Root-pruning is more necessary than in other cases, and should be done in an open standard, as the roots will be more exposed to frost. A first balance kept up between top and bottom, which is not the case when the top is severely pruned in each season. These means may, perhaps, cause fruitfulness, but if the soil or situation be unfavourable it is not so likely to be so. We presume your ground is well drained, for a dry situation promotes fruit-bearing. Near to a manufacturing town, where noxious vapours and other impurities render a healthy vegetation next to an impossibility, fruitfulness in Pear and Plum trees is altogether out of the question.

SHOWS (W. M. Ball).—We cannot make out what you wish to know. The shows of the Royal Horticultural Society, Royal Botanic, and Crystal Palace are advertised in our columns when approaching.

MAGGOTS IN WINTER ONIONS (A Subscriber).—This complaint is more frequent amongst the spring-sown than the autumn onions, but the evil is the same in both. In some seasons and in some grounds it is very destructive. The best remedy that we know is to give the bed a good watering with rather strong soot water—*i.e.*, water in which soot has remained some hours. The strong acid taste the water afterwards has is unpalatable to the maggots, or kills them. Lime is sometimes used in a similar way, but it is not so effective. But when the disease has run to some length remedial measures are of little use, as the evil is done. In soils where this disease is of frequent occurrence, it is thought good practice to dip in a quantity of soot before the seed is sown. This, and a full exposure of the soil to the frosts of winter, will usually insure immunity from this pest.

FUNGI (C. J. S.).—Your Fungi are both abnormal. That resembling fingers is an arrested growth of *Lentium lepidum*; and the Agaric is some species of *Pholota* very much drawn up, from its peculiar habitat near the ram-water eistern. Neither is admissible for the table.

CAMERA (Anxious Learner).—We cannot give you the information, and the gentleman who wrote on the subject is dead.

ASPARAGUS SELF-SOWN—SOWING SEED VERSUS PLANTING (Herbert).—It is desirable to strip-off the berries at the time of clearing-off the haub in autumn, strew them on the bed, and then cover with manure, &c.; but this is only necessary when the beds are thin of plants. For well-furnished beds it is quite unnecessary. In sowing seed to remain permanently, as compared with planting one or two-year-old plants, we have a case in point. In 1871 we sowed beds with seeds, and we planted others with one-year-old plants. The seedlings were thinned out to 1 foot apart, and otherwise treated the same as the transplanted plants. This year on the beds sown we have Asparagus fit to cut, but on the planted beds it is very far from it. The planted beds are fully a year behind the sown beds. Both are full of plants. The beds for sowing the seed are all well prepared as for planting.

DRIVING ROSES (J. B. F.).—The shoots of the Briar in which the buds are inserted should be shortened to about 1 foot above the bud if strong, to 9 inches if of medium vigour, and to 6 inches if weak.

CAMELLIA CUTTINGS AND GRAFTING (Idem).—The cuttings should be entirely of this year's growth, and should be 4 or 5 inches long or less, removing the lower, but retaining two or three of the upper leaves. Pull them in July or August when they are ripe at the base. Grafting is best done in spring, just before the plants begin to grow. The best stocks are those of about the same thickness as the scion, a little larger rather than less. On an old plant the scions should be placed on the side shoots rather than on the stem. All growths at grafting should be stopped, so to cause the sap to flow into the scions, for if shoots are left they would appropriate to themselves what should be forced up to the scion. The scions should be of last year's wood, well ripened.

VINE LEAVES BROWNED (G. S.).—The leaf you sent us was infested with red spider, the under side completely covered with the insect's webs. We should have the Vines thoroughly syringed twice daily, directing the water forcibly against the under sides of the leaves. When the Grapes change colour the syringing should be discontinued. We should also give the border a good dressing of guano, making the soil quite yellow, and wash it in by watering now and then when the Grapes are changing colour. The water used for syringing should be soft and clear.

PRUNING-DOWNS ROSE SHOOTS (C. B. A.).—The shoots should not be finally pegged down until they are ripe, or before autumn, as on their being well ripened depends their surviving the winter. We presume that you mean the summer pegging, to take away the straggling appearance which would otherwise be apparent. Commence to do this as soon as the shoots become firm and will bend without "snapping." It is best done in dry hot weather. The Strawberry, we think, is a small specimen of Keens' Seedling.

DESTROYING WOOD-lice (A. F.).—The best way to destroy wood-lice is to place a little hay all round close to the wall or side of the Mushroom bed, leaving the bed uncovered, and on the removal of this in the morning they will be congregated in the angle formed by the wall and side of the bed; on this pour boiling water. The hay, as removed, should be plunged in boiling water. This repeated a few times will thin their numbers more than anything we know, and applied with care need not destroy more than a very small portion of the bed. It is about the only effective means where they are very numerous.

ADIANTUM CAPILLIS-VENERIS CULTURE (F. H.).—Grow it in well-drained pots 6 or 7 inches in diameter, filled with a compost of three parts sandy fibrous peat, half a part fibrous loam, and half a part in equal proportions of crocks, or pots broken small, and silver sand. Put so that the rhizomes may be only just covered with soil. Water as required to keep the soil always moist, and sprinkle overhead twice daily in summer, then water abundantly, but do not sodden the soil. Afford shade from bright sun. It will succeed in a shady part of the greenhouse, and luxuriate in the stove, but out of doors we have not found it succeed, though it may do so in warm sheltered spots.

STRAWBERRIES FOR EARLY FORCING (D. J.).—Of the Strawberries you enumerated—*viz.*, De Bourg, Sir Joseph Paxton, Oscar, President, and Sir C. Napier, the best for early forcing is Sir J. Paxton, and after it President.

EGGS NOT RIPENING (Maria Hankinson).—Your district is too cold to ripen Eggs away from a wall. By all means cover with glass, and if convenient cover the pots with glass, but under such circumstances they must be artificially watered. The fruit would ripen better if the plants were trained to the wall. From what you say in your letter we do not think it will be

necessary to renew the soil. An angle of 15 will be sufficient pitch for the roof.

SCALE ON PEACH TREES (H. N. O.).—The Peach branch you sent is infested with the Vine scale. *Coccin. Vitis*, occasionally found on the Peach and Nectarine. Now that the scales are in leaf, the best remedy is to brush the branches over with a strong solution of lime, and allow it to remain on for a week or ten days. After the scales have gone the trees with a comparatively mild dose of 250 ft soap to a gallon of water, avoiding washing sulphur to bring it to the consistency of thin putty. Apply with a brush, taking care not to dislocate the buds.

TOWARD FRUIT TREES UNPRODUCTIVE (Idem).—The cause of the trees not bearing well is not but in consequence of their making too much wood. We should advise you to dig round them next November at a yard, less the width of a spade, from the stem, work under the ball to the centre, and cut any roots that may be going down the trench. We would fill up again with the soil taken from it, thoroughly mixing with it an equal quantity of old mortar rubbish. This will check the growth of the trees, and cause them to make short-jointed wood, as well as to ripen it better. Let us know if you have not fruit in a year or two. Be careful to leave the ball of soil to each tree undisturbed, only cutting off the roots in the trench, and those that go down say at 18 inches from the setting-on of the roots.

CERCOUS SPITTLE (N. S. R.).—All its popular names refer either to the saliva-like froth in which it buries itself; to its jumping powers when full grown, for it is closely allied to the grasshopper; or to its appearance at the same time as the cuckoo. It is the *Tettigonia spumaria* of some entomologists, and the *Cercopis, Cicada*, or *Aphrophora spumaria* of others. Its larva enveloped in its froth is especially prevalent upon the young shoots of the White Thorn or Quick; but it also infests the stems of Pinks, Carnations, Lilacs, and many other plants. If the froth be removed, one and sometimes two small, pale green, aphid-like insects are detected. These are the larva or young of the Froth-fly, and appear like the figure marked c in the annexed

woodcut, b representing the froth it emits. By means of its sharp rostrum or beak it extracts the sap of the plant, and voids it as an excrement in the frothy form which is its characteristic. About the end of July it sheds its skin, leaving t in the froth, and comes forth the perfect insect, as represented by the figure marked a, which magnified, and in another attitude, is represented in our second woodcut. About the beginning of August the

males and females may be found in pairs numerous on the plants they frequent. They are of a dirty white color, thickly dotted and clothed with short hairs; head broad and bluntly triangular, with black lines down its centre and sides; eyes, one on each side, near the base of the head; rostrum long, bent underneath its body when not in use; antennae ending in a fine bristle; thorax and shield (scutellum) adjoining the back of the head, brownish. The wing-cases are brown, mottled with ochre, with four whitish patches on the margin; the under wings are transparent and iridescent. The legs, six in number, short, but two hind-legs longest, and formed for leaping. It is not ascertained where the eggs of this insect are deposited, but probably on the stems of the plants on the shoots of which the larvae feed. It appears, however, that they can travel after hatching, for seedlings and plants raised from root-cuttings are often affected. We know of no better plan for destroying the insect than drawing the affected shoots between the fingers, and then dipping these into a bowl of water after each grasp. In the case of Carnation stems and other flowers requiring more tender treatment, all the froth may be taken from the infested branches by means of a piece of sponge, and itself then removed by a camel's-hair brush. It is probable that dusting each froth with Scotch snuff would destroy the insects.

MANNER FOR STRAWBERRIES (Smolton).—It is not good practice to have Strawberries on the same piece of ground twice without a change of crop. We should not be at the trouble to remove the old plants and runners, but would trench them in, placing them at the bottom of the trench along with the first spit. On this give a good dressing of hotbed, stable, or farmyard manure, and then place the bottom spit on the dung, so that your ground will be trenched two spits deep, and the manure will be between the bottom and top spit. We should go further and give a dressing of well-decayed manure on the surface, and fork it in before planting. We have no doubt you would succeed better were you to give the plants a change of ground.

TAN AROUND CURRANT AND GOOSEBERRY BUSHES (Idem).—We should remove the tan in the autumn, and give a good dressing of manure. The tan dug-in is apt to foster fungus in the soil, especially the rougher portions. That indeed it is used need not be removed.

NAMES OF PLANTS (Roberts).—We cannot name florists' varieties. There are regions of *Begonia*, (*J. W.*)—If you send a specimen in flower we will endeavour to name it. (*Euphorbia*).—The leaf with its tendrils is, we think, *Ampelopsis heterophylla* (var. *quinquefolia*), Virginia Creeper, and the frond of Fern probably that of *Adiantum setulosum*, but we cannot be certain from such small fragments.

POULTRY, BEE, AND PIGEON CHRONICLE.

DONCASTER POULTRY SHOW.

The annual Show of the Doncaster Agricultural Society was held on June 26th and 27th. The park in which the Meeting took place is within easy reach of the station, and is well adapted for such a purpose. The poultry and Pigeons, shown in Turner's pens, were placed under a large tent, in which the light was uncommonly good, and the birds seemed very comfortable. Three silver cups were offered for poultry, one being for Game, one for Bantams, and the other for Any other variety. As no cup was offered for Pigeons, the entries were not so numerous as in the first named section.

There were five classes for *Game*, and the birds were unusually good for the time of year. The first class was for single cocks, and the prizes were awarded to Brown Red, Duckwing, and Black-breasted Red, all three being capital in shape and sound in hand. In Black Reds the birds were mostly out of feather, but the cock in the first prize pen was in high order though badly matched. The hens were rather large and broody, though otherwise good. Brown Reds were a grand class, the competition being close; and the cup was awarded here to a perfect pair of close-feathered birds. Duckwings, with the exception of the first and second-prize pens, were not good as regards the cocks, but the hens to which they were matched were very good in colour. Game any other variety were all Piles, most of the best birds being much out of feather. The prizes were awarded more to quality for Game purposes than feather, and in this respect the birds would compare favourably with the rest of the Game classes. Of *Dorkings* the Silver-Grey were large and very good in colour, but the Dark Greys were more particularly good in feet and size rather than colour. In *Spanish* there were four pens, all of which were good, and, with the exception of the first-prize pen, great difficulty was felt in awarding the prizes, so close was the contest, and the cup for their section was awarded here. *Cochins* were more numerous, but with the exception of the three winning pens, which were all Buffs, were not in good order. *Brahmas* (Dark), were a large class and the quality very high, the shape and size of some of the hens being very striking, as also the lacing on the plumage. Light Brahmas were but poor in all respects. *Silver-spangled Hamburgs* were all good and the prizes keenly contested, the first-prize pen being very even in spangling, though the second contained a splendid hen. *Silver-pencilled* were good in point of marking and plumage, and also very neat and good in style. *Gold-spangled* were a very bright lot, the shade of light being exactly suited to the variety, and showing off the birds to great advantage. *Gold-pencilled* were failing in colour and getting somewhat shabby, though in point of quality the birds were good, although the second-prize cock was somewhat darker than it is advisable to breed them. In Black Hamburgs there were but three pens, but these were all very good, the first-prize pen taking precedence on account of brilliancy of plumage only. *Polands* were all Golden and of fair quality, and in nice plumage. Of *Bantams* there were not heavy entries, and, with the exception of the winners, there were no good birds shown. In single cocks the winners were Black-breasted Red, and the cup for the section was won by the first-prize bird, which in our opinion is the embodiment of quality as a Black Red Game fowl, and it is to be regretted there are no such birds of this colour among large Game fowls at the shows this season. The second was a fair kind of bird, but large in body and wing, and thin in chest and shoulder. In the class for a Red cock and hen of any age, the first-prize birds were very forward chickens in full feather, in fact the second and third being adult birds which do not require special notice. In the Variety class the first prize went to Piles and the second to Duckwings of fair quality. Black Bantams were a nice lot and in good feather, and, there being a class for Whites, six entries were the result, the winners being good specimens.

Turkeys and *Geese* did not show to advantage on account of the loss of plumage, but they were very large; and in the latter, Toulouse were first and White Emblen second. *Aylesbury Ducks* were a good lot, although failing in feather to a great extent, but size and quality of bill were extremely good.

Pigeons came next, and in Carriers and Tumblers there was only one entry in each class, but the birds were worthy of high competition. Pouters had two pairs of Whites, and both good. In Doves a pretty pair of foreign Whites were first, and a very good pair of Blue English second. Except the first in Barbs, the others were very poor. *Jacobins*, all Red, were very good and in nice order. *Trumpeters* had but one good pen, these being of the newly imported variety; and Nuns only one pair, which was very good. *Dragoons* were fair birds and all Blues; and in Antwerps all were Duns and very good. The first-prize Magpie was Red and the second Yellow, the former pair being almost perfect in colour. In the Variety class the first-prize

birds were Buff Isabelle and the second Ice Pigeons, both pairs being all that can be desired; in Fantails only the first-prize pair were noteworthy, but they were perfect specimens. In the Selling class Ice Pigeons won both prizes, and both pairs were extremely good and cheap.

Game.—*Cock*.—1, C. W. Brierley, Middleton. 2, F. Sales & Bentley, Crowle. 3, C. Chaloner, Whitwell. 4, T. Mason, Lancaster. *Black-breasted Red*.—1, C. Chaloner. 2, T. Bottomley, Shelf. 3 and 4, T. Wood, Scotton. *Brown and other Reds, except Black-breasted*.—1, C. W. Brierley. 2, T. Mason. 3, F. Sales and Bentley. c. C. Chaloner.

Game.—*Duckwings and other Greys and Blues*.—1, C. Chaloner. 2, E. Windwood, Worcester. 3, F. Sales & Bentley. *Any other variety*.—1, C. W. Brierley. 2, H. C. & W. J. Mason, Drighlington. 3, H. Walker, Gomersal. c, F. Sales and Bentley.

Dorkings.—*Silver-Grey*.—1, J. Robinson, Garstang. 2, W. Roe, Newark. 3, O. E. Crosswell, Bagshot. *Any variety*.—1, J. Newall, York. 2, W. Harvey, Sheffield. 3, J. Robinson. c, W. G. Lysley, Rawtry Hall.

Spanish.—1 and Cup, J. Powell, Bradford. 2, Burch & Boulter, Sheffield. 3, J. Boulton, Bristol. *the E. Brown, Sheffield.*

Cochins.—1, F. E. Ansell, Cowley Mount, St. Helens. 2, W. Harvey. 3, H. C. and W. J. Mason, Drighlington. *hc, W. Whiteley, Clough.*

FANTAILS.—1, J. F. Loverside, Newark. 2, W. W. Fowler.

ANY OTHER VARIETY.—1, H. Yardley. 2, W. Harvey. *hc, J. E. Crofts (2).*

SELLING CLASS.—1, W. Harvey. 2, J. E. Crofts. *hc, W. W. Fowler.*

JUDGES.—Mr. James Dixon, North Park, Bradford; Mr. E. Hutton, Pudsey.

THE CHATTERS POULTRY AND PIGEON SHOW.

THERE cannot be a doubt that the entries made this year for the Chatters Show were considerably lessened in numbers by so many other shows being held simultaneously; still, it was most gratifying to find the majority of both poultry and Pigeons shown were of unusual excellence. It proved to be a very largely attended meeting, as the weather was not only fine, but the railway companies, by liberal fares and special trains, aided the success in no slight degree. The arrangements of the tent and general fittings were excellent, and every attention was given to the birds exhibited.

The entry of *Dorkings* was extraordinarily small, the best-shown varieties being the Silver-Greys and the White Dorkings. As to the *Game* fowls, they were in quality much beyond those to be met with at ordinary poultry shows, Messrs. Hall and Matthews exhibiting first-rate pens, though some of the birds were about moulting, consequently were not in the best of show trim. *Cochins* comprised a few good Whites, and a pen of dark Cinnamon-coloured that were worthy of favourable mention, but most of the pens were matched badly. Some early Dark *Brahma* chickens took the lead on the award list, pressed by some adults that were entered by the same exhibitor. An extraordinarily well-plumaged pen of Golden-spangled *Hamburgs* were winners of the highest premium in their appointed class, and also the extra prize as being the best pen of any variety of poultry in the show-tent. The other extra prize, given to the best pen shown by a local exhibitor, was secured by Crève-Coeurs. In *Hamburgs*, also, the Silvers-spangled and Golden-pencilled were the best kinds shown. Of *Spanish*, not even a single pen was entered—a quite unexpected result, as heretofore the competition has been good; it appears, however, that this breed is not constitutionally suitable for the district, and they are therefore not local favourites. *French* breeds were a fine class, and the *Game Bantams* were very far beyond any hitherto seen in this neighbourhood, nor were the Black Bantams less worthy of the attention bestowed on them by visitors. The *Geese* and *Turkeys* were very fine large birds, well shown too, considering the lateness of the season.

point of view. Mr. J. G. Dru, 2, Gloucester Terrace, New-castle-upon-Tyne, is the Secretary.

DUCKS WITHOUT WATER.

A CORRESPONDENT of the American "Country Gentleman" says—The question is often asked, Can Ducks be reared with profit without the accommodation of a pond? I answer, They can. I have raised the Rouens two years without any water except what was given to them. When young I used a common pie-tin, and as they grew a milk-pail was placed in its stead, thus saving any from being drowned. I have had good success, seldom losing one.

Rouens, under ordinary circumstances, will be found as profitable as any variety, for the following reasons: First, the rapidity with which the young Ducks grow. It is not uncommon to see them in full feather and weighing 4 lbs. when eight or ten weeks old, yielding very fine flesh for the table, which makes them valuable for early market. Second, when full grown they often weigh 9 to 10 lbs. each. Third, as egg-producers they rank the best, laying in the full a good number of eggs. Then, with a little cessation in midwinter, they recommence in spring, when other varieties have only just begun. They make a nest and are zealous of keeping it, avoiding the trouble of shutting them up at night. Fourth, the eggs are large and rich, making them valuable for culinary purposes. Fifth, they are the most determined stay-at-home birds imaginable, seldom if ever rambling beyond sight of home, never troubling the neighbour's crops, or keeping you travelling nights to bring them home. This breed is highly esteemed by breeders for their size and deliciousness of flesh. It may be imagined from their large size, that they must consume more food than our smaller varieties. On the contrary, they are remarkable easy keepers, and require less food than the common Duck.

[The above is perfectly correct as regards ducklings, but old birds must have a swim and a depth of 18 inches at least in the breeding season. It is because they are better without water that we always advise rearing ducklings in a pigsty. We have never found Rouens very early layers, and 9 to 10 lbs. are the top and an exceptional weight.—EDS.]

A HORNED CANARY.

AT No. 30, Mill Street, Ludlow, Salop, a Canary may be seen with horns. It is ten years old, yellow, a hen bird, fairly proportioned. Six months since, the owner noticed an excrescence on the bill, which gradually became a horn, and has attained the length of five-sixteenths of an inch, inclines backward and a little outward; appears to be of the same material as the beak, but is somewhat transparent and rather flat than round. Three to four months since, the second horn began to appear, and is now three-sixteenths of an inch in length. The first one appears to have attained maturity, the second to be in progress. The position of the horns is between the breathing orifices and feather-growth, in a line with the eyes and the point of the bill. The bird was, some time back, in bad health, as a child when cutting teeth, but is now quite well and tunes better than in any previous year. It is of average note-power.—S. R. J.—(*English Mechanic*.)

BEE SUPERSTITIONS.

LAST August I purchased a swarm, for which I paid 10s. So far as I could judge from my limited experience with bees, for the first fortnight they appeared to be doing well, but one night, about eight o'clock, I found they had deserted the hive, and were on the ground in a cluster the size of a large plate. I gently lifted the hive and placed it over the cluster. About ten o'clock I found most of the bees had gone up into the hive, which I then returned to its stand. For a short time the bees appeared to work, but one day, thinking they appeared very quiet, I lifted the hive, and discovered that it was quite empty of bees. There were three nice pieces of empty comb. I think the bees were teased by wasps. Our parishioners tell me that I did two things wrong, and that in consequence my bees could not thrive. One was to give money for them, which is always unlucky; the other was that I did not have them at the right time of the year. I ought to have had them on old Christmas-day. Is there anything in these ideas? How had I better make a fresh start, and what little handy-book would you recommend? What do you think of Mr. Edwards's pamphlet, and the hive he recommends?—A CLERGYMAN'S WIFE.

[The truth is that you were taken in; we hope not, however, by any one of your own parishioners, who might chuckle over having "done the parson's wife." A swarm bought in August, that had only three small pieces of comb built when it died, was not worth half a crown. The bees could not get enough to live on, and deserted their hive in the forlorn hope of falling into better quarters. We can hardly suppose that you can give any credence to the absurd superstitions of villagers respecting the

purchase of bees, or the time at which they ought to be procured. The idea as to giving money being unlucky is not at all uncommon, though, perhaps, not so prevalent as it used to be; but the second idea advanced by your parishioners we have never heard before.

Your proper method of procedure is to purchase a swarm at the end of May or very early in June, making an imperative stipulation to have it brought to your garden on the day of its swarming; or to purchase a good strong established stock in the autumn or early spring. If you wish to stock any of the improved hives, you had better wait until next year, and on having a swarm brought to you, knock out the bees the same evening, and place your hive over them, lifting it up on to its stand as soon as the bees seem to have gone up, either that night or very early the next morning.

Probably our little publication, "Bee-keeping for the Many," which can be had at our office by sending five stamps, would suit your purpose. We have but little acquaintance with the pamphlet published by Mr. Edwards, and none whatever with the hives he advocates.]

DEATH OF THE TRICK TERRIER BILL JOHNSON—HIS FEATS.

THERE are no doubt hundreds of our readers who have seen or heard of the famous trick terrier Bill, owned by Captain H. W. Johnson, of this city. Bill was a great favourite wherever he was known, on account of the remarkable feats which he could perform, and the wonderful intelligence he possessed. It seemed at times that he had the reasoning faculties of a human being instead of the brute instinct generally attributed to canines. The animal died yesterday at Captain Johnson's country residence, Yang-tse Villa, Stamford, Connecticut.

There are comparatively few men who are so well known in New York as was this dog, and his death will be regretted by all who have witnessed his performances. Only a few days ago James Gordon Bennett, jun., of the *Herald*, offered a fabulous sum for Bill, but Captain Johnson would not sell him at any price, although he valued him at \$10,000. He was almost as great a traveller as his master, and had visited nearly every quarter of the civilised, and some parts of the half-civilised globe. In fact, Bill had a world-wide reputation.

While in China he delighted the "pig-tails," who regarded his performances with wonder akin to awe. In Paris he attracted universal attention wherever he went. Although his master might have sold him to Barnum or other curiosity-hunters for a fabulous sum, the animal was not to be disposed of for money. Among the feats performed by this dog, was one never attempted by any canine quadruped. He would stand upon one foot, and balance himself on the nozzle of a champagne bottle.

Whenever his master entertained friends at dinner Bill was always present. The dog would occupy a seat beside his master, and when the wine had been passed round would place his fore paw upon the cork, and hold it there, as much as to say, "Gentlemen, you have had enough." While at sea, and when the vessel was pitching about at a violent rate, Bill would balance himself upon four champagne bottles, standing with a foot on the nozzle of each. He could stand upon his fore or hind legs, and maintain his position steadily enough to have his photograph taken. The feats of bringing articles for which he was sent, watching his master's property, &c., were very common-place matters for Bill.

Bill was ten years old, weighed 12 lbs., and was a full-blooded black-and-tan. Captain Johnson purchased him when six months old of Mr. Charles Kimball, new agent of Colonel James Pisk's line of steamers. Bill's cold corpse is now in the hands of a skilful taxidermist.—(*Poultry Bulletin*.)

THE HOMING PIGEONS AT SOUTHAMPTON SHOW.—In your report of the Hunts and Berks Agricultural Society's poultry Show at Southampton, you refer to the Homing Pigeons as a new and interesting class, and state you will be curious to know the result of their flight. The birds from Reading all returned, and flew a sweep like race home from the showyard; the conditions of the sweep being, the birds to be caught and conveyed to the club house for satisfaction. The result was as follows:—Mr. C. H. Buckland's bird first; Mr. J. W. Barker's second; Mr. J. Albury's jun., third; my five birds taking two hours three minutes to complete the journey, although they had flown from Southampton railway station on the previous Friday in one hour forty-two minutes.—I. W. BARKER, *Hon. Sec., Reading Pigeon Society*.

FECUNDITY OF THE TAME RABBIT.—The *Aigle du Midi* states: "A farmer named Pinel, of Revel, in the department of the Haute-Garonne, France, has lately commenced breeding Rabbits on an extensive scale for consumption, and that he expects the operation to be successful in a commercial point of view. In the space of five months, from May last, he, with fifty female

and five male Rabbits, obtained 1300 young, and he now intend to have 200 females. By allowing these latter to produce only every two months, instead of every month, as they can do, he calculates that he can procure 500 Rabbits a-month, or 6000 a-year. He has had constructed a large shed, 30 yards long by 20 wide and 40 feet high, and in it are 140 compartments, of which ten are set apart for young Rabbits separated from their dams, fourteen for the adults, twelve for the males, and the rest for the doe Rabbits and other purposes. Pinel makes this calculation: Out of 270 Rabbits born every month, the average number of deaths is twelve, so that there remain for sale 258, which can be disposed of for 12 cents each, making \$56.76, or \$681.12 a-year. This sum is increased to \$931 by the sale of the manure. The expense of producing 258 Rabbits is estimated at \$274, so that a clear profit remains of \$657. As Rabbits can be fed in great part on the refuse of the farmhouse and farmyard, it is thought that they might in many localities be bred to advantage."

OUR LETTER BOX.

Books (*Apiry*).—"The Bee-keepers' Manual," you can have it free by post from our office if you enclose five postage stamps with your address.

CHICKENS ILL AND DYING (*C. Holt*).—We are at a loss to know why your chicken died. It seemed to have had all that was necessary for health and comfort, but we do not think your feeding is as judicious as it might be. Indian corn is not good for chickens. Change your diet. Give them ground oats or barley-meal for the first meal in the morning; give them bread crumbs and table scraps afterwards; at mid-day then some whole barley, and wind up with a feed like the morning. Discontinue wheat, Indian corn, and the cooked meat. If the discharge continues, give a small teaspoonful of castor-oil.

BRABMA CHICKEN DYING SUDDENLY (*J. Evans*).—Where a well-fed and healthy chicken (as yours was before it died) becomes suddenly ill, and dies spite of remedy, we always attribute death to some poisonous food. We are careful in hunting at anything of the sort, because it opens a wide door, and causes an uneasy feeling which may have no real foundation. The chicken arrived in a very decomposed state, rendering all examination impossible. Poisonous food may be picked up accidentally, without evil act or feeling on the part of anyone. Death may be the result of injury either to the head or the spine, and it is more than probable, as two were taken and the others remain in health, that some such accident was the cause of death. The evacuations from healthy birds should be brown and white. A few birds must die, and we will hope these are the two, and that the others are going on well. We are always happy to answer any questions. Should you have any more to ask about these chickens, give us more detailed information about their feeding.

PLANTS SUPPOSED TO INJURE FOWLS (*T. T.*).—The flower is hemlock; the leaf is a fern, which is certainly harmless. The chickens may eat the hemlock, which may cause the mortality. There is nothing among the other plants you name that would kill poultry, and there is no reason why chickens should always die in May, nor do we think they would eat hemlock.

BONE-DUST FOR FOWLS—LEG WEAKNESS (*R. E. H.*).—We took the chemical part of your question to one who is learned in such matters. He said:—"The sulphuric acid will not harm the fowls; it is only added to convert the phosphate of the bones into super-phosphate." Of course, we said, how came we to forget that? We feel more at home about Light Brahmas and leg weakness, and so, instead of telling you where the crushed bone can be had unadulterated, we tell you you ought not to want it at all. We cry out continually to follow nature. We do it with our own birds, and we have no leg weakness or anything of the sort. Eschew all modern inventions, and try to feed your fowls as Pheasants and Partridges feed in a state of nature. You never see them with leg weakness—an entirely modern disorder. They get nothing that you cannot give. Avoid stimulating and spiced foods. If you can get ground bones, give them, they possess all the material for bone; if you cannot, give barley-meal. The husks of oats and barley contain chalk. Vary the mid-day meal with bread—scraps from table and kitchen. Be sure that weakness is not the result of inter-breeding, and consequent weak constitutions. If it is, no feeding will cure it.

TROUBLE POULTRY SHOW.—In Silver-Grey Rabbits we are informed that A. H. Eastern took the first, and S. Ball second.

PARROT SUFFERING FROM SORES (*L. M. S. P.*).—The best treatment is to have a sort of enameled male, such as one sometimes sees round the necks of horses which have sore places. It should be made of pieces of wood, each about 2 inches long; the wood to be round, like a black-lead pencil, the ends rounded to prevent their hurting the bird, and each strip should have two holes made in it a little way from each end, through which holes a piece of string should be passed, but a knot must be tied on both sides of each piece of wood, so as to keep them from slipping out of place. The accompanying sketch will give a clear idea of what we mean. We would also recommend a very small quantity of magnesia to be put into the drinking water of the bird now and then.

WOODEN HIVES (*Wallaston*).—If wood is so very unsuitable a material for bee hives, why is it so largely used by American, German, and English bee-keepers, to say nothing of those of other countries having, with those mentioned, every extreme of temperature? We have, for many years, had colonies in both wooden and straw hives, and have generally found our strongest and most forward stocks in the spring to be in wood. There is frequently more or less of moisture, which may collect on the under side of the cover, but we have never found it to be very injurious, provided the stocks are strong and well-provisioned, and that the floor-boards are changed or cleaned in the spring. There is no objection to your proposed plan of boring four holes through each side of your boxes, and covering the

whole with lead-bands. These holes must not, however, be covered with zinc or the bees will soon show their appreciation of your efforts to provide them with ventilation, by effectually stopping up every hole in it. The best mode of effecting your object is to have mats of straw, the bands of about 1 1/2 inch thick, not too tightly twisted together, substituted in October for the usual wooden cover. They may be kept down by slips of wood at the two sides of each hive, projecting a little beyond the cover, and tied with strong cord passing under the floor-board.

DISTILLING ROSE WATER (*A. S. J. M.*).—Put 4 lbs. of rose petals into a pan with three quarts of river water, and leave the mixture four-and-twenty hours; then put it into the still, and distil from it as much odoriferous water as you can. Take off the still, throw away its contents, and rinse it out well. After this fill it to two-thirds with fresh-gathered rose petals, on which pour the above drawn rose water; distil this, and when you have procured as much good rose water as it will yield, let the fire go out gradually. Do not continue the distillation until the petals scorch. To avoid this danger the still may be plunged in a water bath, and the bath placed over the fire. A temperature between 200° and 212° will be enough for the distillation.

REMARKS.

- 23rd.—Fine day, very hot sun.
- 24th.—Fine day throughout.
- A fine week of warm June weather, especially the last few days.
- 25th.—Rather dull morning but beautiful afternoon, evening, and night.
- 26th.—Moderately fine all day, but with one or two sprinkles of rain.
- 27th.—A very fine day, bright and sunshiny with a pleasant breeze, though sometimes rather strong.
- 28th.—Rather dull in the morning, but fine afterwards.
- 29th.—Fine and warm in the morning, rather dull after 2 P.M., rain in the evening, at times very heavy.
- 30th.—Rather dull morning, but no rain till about 4 P.M., after which time it rained more or less all the day.
- July 1st.—Fine pleasant day, rather warm, but by no means oppressive.
- Very similar to the previous week, except that on Sunday and Monday there was heavy rain. The temperature in sun has also been lower. The total rainfall for the first six months of 1873 (10.20 in.), is 1.63 in. below the average of the six years, 1860-65.—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 2.

Very little alteration to make, except that out-door Strawberries have come in with a glut, growers finding a difficulty in making a clearance, and prices ranging from 3d. to 1s. 6d. per punnet.

From observations taken near London during forty-three years, the average day temperature of the week is 75.6; and its night temperature 59.6. The greatest heat was 94°, on the 14th, 1847; and the lowest cold 31°, on the 10th, 1853. The greatest fall of rain was 1.69 inch.

ORNAMENTAL PLANTING.—No. 5.

In mixed groups and borders of shrubs we have a feature of such interest and importance that it merits the most careful attention and study. The effect of one form with another is here fully realised, and the peculiarities of each plant are turned to the best account; those of sombre hue and heavy mould forming admirable foils to others possessing the sprightly grace which slender growth, upspringing or pendulous, and light-coloured or variegated foliage, impart. Those shrubs retaining healthy foliage throughout the winter,

and hence termed evergreens, afford the most pleasing variety when associated with deciduous forms, imparting an air of warmth and fulness to what would otherwise appear naked and sterile in a very great degree during that cold period of the year; and when the warm skies of spring and early summer clothe the bare death-like deciduous forms with fresh foliage, crowning many, too, with gay flowers, an air of freshness, life, and animation pervades the group, which thus changing in its aspect with the seasons at no time appears heavy or monotonous, but contains within itself that charming variety so justly admired and sought after.

In the following arrangements of trees and shrubs I have excluded any of an uncertain or doubtful character,

Plan of a Portion of a Mixed Border of Shrubs, with a Sheltering Belt of Two Rows of Trees behind.

naming only such sterling kinds as are to be depended upon. The four detached groups are arranged in the form of a circle. That being the simplest and most elegant of all forms, is, I think, the best for general purposes. Moreover, by studying the most prominent characteristics of the plants named, the circular arrangement may very easily be modified or extended to adapt it to beds of more complex or irregular outline.

Group of flowering deciduous shrubs (see accompanying figure):—

1. Ribes sanguineum. Crimson.
2. Philadelphus grandiflorus. White.
3. Dentzia crenata flore-pleno. Rose.
4. Spiraea arifolia. White.
5. Cytisus hirsutus. Yellow.
6. Spiraea Douglasii. Pink.
7. Ribes aureum. Yellow.
8. Cytisus pallidus. Cream-coloured.
9. English Laburnum. Yellow.
10. Double Crimson Thorn. Crimson.
11. Syringa (Jaloe) Dr. Lindley. Deep crimson.
12. Anagallis communis. Pink.
13. Magnolia conspicua superba. Wht.

Evergreen group:—

1. Berberis Darwinii.
2. Viburnum Tinus.
3. Cotoneaster Simonsii.
4. Ulex europaea flore-pleno.
5. Kalmia latifolia.
6. Ligustrum japonicum.
7. Rhododendron Breganzium.
8. Cistus ladaniferus (Gum Cistus).
9. Ilex Aquifolium.
10. Rhododendron Barclayanum.
11. Cerasus lusitana.
12. Arbutus Unedo.
13. Cupressus macrocarpa.

Mixed evergreen and deciduous group:—

1. Pernettya angustifolia.
2. Ribes aureum.
3. Weigela rosea variegata, grafted and trained to the form of a cone.
4. Mahonia Aquifolium.
5. Erica medieterranea.
6. Berberis Darwinii.
7. Kalmia latifolia.

8. *Cytisus albus*.
9. *Laurus nobilis*.
10. *Acer Negundo variegatum*.

11. *Phillyrea latifolia*.
12. Golden Queen Holly.
13. *Betula incisa pendula*.

Mixed evergreen and deciduous group with plants of bolder type:—

1. *Juglans laciniata*.
2. *Garrya elliptica*.
3. *Sambucus argenteo-variegata*.
4. *Cupressus Lawsoniana*.
5. *Crataegus Oxyacantha flore-plena*.
6. *Ilex Aquifolium*.
7. *Pyrus Malus floribunda*.

8. *Juniperus chinensis*.
9. *Rubra Pseudo-Acacia*.
10. *Rosa Nordmanniana*.
11. *Betula alba*.
12. *Picea Finsappa*.
13. *Picea pectinata*.

There are two methods which may be followed in the culture of such mixed groups and borders. The first is to plant the shrubs so far apart that each may eventually be brought to its fullest development of form and size; and the other is to plant more thickly, so that the growth of each shrub may soon meet and become merged in that of the others near it; thus forming a picturesque thicket, which, while it is in some degree ornamental, and is very suitable for certain positions, notably where a thick low screen is required, yet has no features of sufficient interest to attract more than a passing glance. But when the first method is followed, the plants individually and collectively are constantly growing in beauty and interest. It is true that by planting sufficiently distant to afford each shrub space for this full development, the bare surface of the soil is exposed to view for a longer period than is the case when a thicker system of planting is followed; but even this trifling objection may be overcome by filling the intermediate spaces with low-growing plants, to be gradually removed as the growth or training of the permanent occupants may require, taking care constantly to replace the exhausted soil with that which is perfectly fresh and sound.

I have given the colours of the deciduous flowering group, but refrain from descriptive notes of any of the kinds named, as a future paper will be specially devoted to a subject of so much importance.—EDWARD LUCKHURST.

THE PROVINCIAL SHOWS OF THE ROYAL HORTICULTURAL SOCIETY.

THESE annual meetings are so important to the Royal Horticultural Society, and to the interests of horticulture generally, that I venture to offer a few suggestions, based, as I think you will testify, on experience, and calculated as I believe to assist in promoting a more satisfactory state of things as regards the harmonious working of the arrangements.

Most of the shortcomings and insufficient organisation which almost yearly form subject of complaint in reference to the management of the provincial shows, arise, as I believe, from the want of a clear and definite understanding between the Council of the Society and the Local Committee for the time being as to what are their several duties and obligations. I would therefore suggest the desirability of this doubt and uncertainty being once for all removed, by the Council considering itself, as it is unquestionably regarded by outsiders, responsible for all arrangements during the show week. It possesses, or ought to possess, a staff of officers familiar with the requirements and exigencies of these great shows: experience must have taught them what plans work well, and in what respect past shows have been deficient in organisation; it is peculiarly and permanently interested in the smooth working and success of the arrangements. It is the Council, then, and not the local committees that the horticultural public justly hold responsible for defects and omissions, and it is the Council which is in duty bound to foresee and prevent them in future.

The local committee has its natural and proper duties, and they are clearly defined in practice if not formally set forth in any official document, and they consist chiefly in raising sufficient funds to enable the issuing of a liberal and special schedule of prizes complementary to that of the Society; also in working-up local interest in the show, the sale of admission tickets beforehand, and the adoption of such means as shall, as far as possible, insure such a large attendance of visitors during the continuance of the show as to raise a sum of money sufficient to cover all expenses, and leave a handsome balance of profit for the Society.

There are many other things which a good local committee can, and doubtless will do. They can invariably give advice on local circumstances of the utmost value to the Council, and their opinion on such matters ought to be always sought and carefully weighed; and they can frequently secure the support and influence of important residents in their neighbourhood.

In the event of the local secretary being an energetic man of business, and especially if he be an enthusiast in horticulture and experienced in the details of show management, he can render the Council invaluable assistance in numerous ways; but the more thoroughly he performs the duties of his office the smaller will be the time at his disposal for anything else, and he ought certainly not to be held responsible for those general arrangements which it is the duty of the Council to make, and which for the comfort and convenience of exhibitors it is essential should be made. As, however, it frequently happens that the local secretary is not experienced in the details of show management, and can rarely or never be familiar with the requirements of such extensive gatherings as the provincial shows of the Royal Horticultural Society, I think it is tolerably clear that it is not either reasonable or judicious to trust to him for such arrangements. The Council, then, with its officers, must be the responsible body. Their accumulating stores of experience should render the annually recurring work a less laborious and more successful one year by year. With all diffidence I would offer for their consideration the following suggestions:—

First, That the Council should appoint as an executive committee for the management of the provincial shows not less than two of their body, who must be first-class men of business, able and willing to do real work, with the addition, perhaps, of the local secretary or some other member of the local committee selected for his fitness by that body; these, aided by the Assistant Secretary and the Superintendent of Shows, should have full power to make the necessary arrangements, and should be held responsible for all defects. This executive body ought to take up its abode in the show town a few days before the show, in order to make the members of it familiar with the exact state of things and the condition of the arrangements; to see that all needful preparations have been made, or, if not already made, to make them. The details are so multifarious and so varying from time to time that I will make no attempt at specifying them. I will simply add that to defer going to the show town to the day before the opening—and I know this has been the case—is almost to insure unsatisfactory results.

Second. Among the arrangements I should consider the following essential:—(a), To ascertain what lodgings, plain, clean, and as inexpensive as possible, may be secured for exhibitors and their assistants during the show week. Advertisements in the local journals stating what is required would generally elicit abundance of replies. From these a register might be compiled which, with a map of the locality, should be kept in the superintendent's office ready for reference on the arrival of exhibitors, &c. (b), To provide (but of course not to pay) for the horsing of exhibitors' vans. In towns where there are two or more lines of railway this is extremely necessary. The railway officials, if applied to soon enough, will invariably find the necessary supply of horses, &c. But exhibitors ought to know before leaving home that this has been done. (c), To issue a programme of the arrangements, giving exhibitors, *inter alia*, the names and addresses of the officials of the various railways to whom they must give notice in order to ensure the attendance of horses, &c. A copy of this programme should be sent to every person who has entered to exhibit; and it should be inserted in all the horticultural journals issued in the week preceding the show. The horticultural world would thus have published to it what it always desires to know, while much correspondence would be rendered needless, at the same time that mistakes would be prevented.

Third. I commence a fresh paragraph with a suggestion which I trust will receive due consideration. It is well known that exhibitors and horticulturists, as a body, have for years past been asking for the accommodation of a room at the provincial shows where they may have a chance of intercourse with their friends and with other horticulturists who, known to them only by name, are among those whom they desire to know better; a horticultural club-room, it has been called. Surely the Royal Horticultural Society cannot think it beneath its dignity to extend its influence to foster social intercourse among the votaries of the pursuit, the progress and development of which was one of the primary reasons which called it into existence. Now for my suggestion: Let the Council at once provide a moveable structure, so made that when not in use it may be packed up and stowed away, but which shall be used at all forthcoming provincial exhibitions. It need not be very expensive, but it should be made of durable materials and of ample size. Let it contain three rooms, one being as large as the other two. The two smaller rooms to be occupied, one

by the Superintendent of the show as his office, and the other by the Local Secretary; the largest room being reserved for the club room. The latter should be under the charge of a trusty and well-informed attendant, who might receive all letters addressed to exhibitors at the show ground and distribute them to their owners on application; he might also be the depository of messages, &c. A large room would not be needed, but it should be furnished with a long table and chairs, writing materials, &c., and might be used for letter-writing, interviews, &c. The building would in reality be the official head-quarters, and, having been seen once, would be recognised readily enough on all future occasions. Frequenters of these shows know too well the bewilderment they are always in as to where the officials are to be met with. With such a structure placed conveniently near the tents, this source of annoyance, loss of time, and inconvenience would be entirely removed, and a desideratum would be supplied by the club room. If expense be a consideration, then I venture to think that exhibitors will cheerfully contribute their share of the cost in order to secure such a great addition to their comfort.

Fourth. But now suppose the executive committee to be on the ground in advance, the official head-quarters to be duly inaugurated, the machinery of the show perfect, there yet remains a lubricating agent wanting to insure the smooth working of the machine. Need I say that courtesy is the lubricator? I mean, let the Council and their officials then insure a good stock of courtesy to keep things smooth; let them show a fair consideration to those who alone make these shows a possibility—not a fussy condescension, but a thoughtful gentlemanly bearing towards their fellow horticulturists, and the future of the provincial shows will be more flourishing than has been their past.—LOCAL COMMITTEEMAN.

I ENTIRELY concur in the pertinent remarks of Mr. Peach relative to the shortcomings of the Royal Horticultural Society, with one exception—his exonerating of the director of floral shows, as he calls him, from any blame. Now, in many of the points I believe the blame to be mainly due to him. He had a *carte blanche* for the arrangement of the tent, the Local Committee were willing to allow him whatever he needed, and what was the result? First of all the tent. This and the arrangement are simply a reduced copy of the International Exhibition tent designed by Mr. Gibson, and yet show after show we get the same—the same bare poles and beams, the same insignificant cascade, the same absurd fountain. And then the disposition of the plants. Who is accountable for the mal-arrangement of them if it be not the director of the floral shows? Who but he placed Mr. Baines's and Messrs. Cole's plants where they were, or hid the splendid *Fuchsias* out of sight, or filled up the centre with plants?—interesting, no doubt, but that made no show. He is evidently no originator. That he is no artist one can at once see. Let the difference between the gardens at South Kensington now and what they were bear me out.

And then the arrangement (?) for the luncheon. Surely it was left to him, and he could have at least arranged that those who were engaged in hard work should have had a quiet meal instead of being mixed up with any who chose to come in. Could not the Council make some change, and place the direction of this provincial show either in the hands of the local committee, or in that of some one who has some taste, and who can combine the *suaviter in modo* with the *fortiter in re*?—IGNORAMUS.

THE Secretary, W. H. Lindsay, Esq., has consulted some of the leading exhibitors and others of sound judgment to ascertain what measures should be adopted to render the country exhibitions of the Society far more satisfactory than was that recently held at Bath. After much discussion it was unanimously agreed that each Show should be of four days' duration, commencing on Tuesday, opening each day at 2, and closing at 6 p.m. on the Friday, and that articles for exhibition should be received not later than 9 a.m. of the first day. The desirability was fully recognised of having a tent or room on the exhibition ground where the committees and exhibitors can meet. It was unanimously recommended that the Council should consult competent persons relative to persons desirable to act as judges, and that the judges should be in threes to each division assigned to them; also that there should be a manager appointed to each tent to give information and to see that care be taken to facilitate the inspection of the exhibits.

Moreover, very strong opinions were expressed that exhibitors should be shown more attention and courtesy.

THE GLADIOLUS.

It was somewhat curious that the week before Mr. Witherspoon's letter appeared in the Journal I had been talking to one or two persons as to the probability of nitrate of soda being good for the Gladiolus. I had noticed the remarkable difference in some fields of Wheat near me where the nitrate had been used, and admired the wonderful glaucous character of the blades; and although I believe there is no analogy between the Wheat and the Gladiolus, yet it had occurred to me that perhaps what was good for one might be beneficial to the other, and Mr. Witherspoon's letter clearly establishes the fact. He does not say how he uses it, or in what proportions, and as he has found it so beneficial, it would be a boon to many to know more about it. By-the-by, in writing about the advice given by some to plant in new ground and deepening it, I had not Mr. Witherspoon in my thoughts, but, notwithstanding what he says about the wireworms not liking the nitrate, I am not quite convinced; they seem so impenetrable to anything that I have ever tried, that I should be delighted to hear that anything was too much for them.

As far as we have gone this season I can say my Gladiolus look well; but, then, I never like to rely on their appearance, as so many things come in to mar one's hopes and prospects. I hardly think that the spikes will be quite so large, but there is a good deal of health in the shoots, which makes me hopeful. My friend, Mr. Banks, complains of his having suffered by the dry weather; from other growers the accounts vary, but probably in a week or two we shall hear more about them.—D., Deal.

THE ROYAL VINEYARD GRAPE.

In the Journal of June 26th (page 507), "J. T." holds up this as "a first-class late white Grape," but does it set freely? A few years since I gave the result of my experience of this, the worst-setting Grape I know, and how I succeeded in setting every berry by simply drawing the hand over the bunch when in flower, charging the hand with pollen from Lady Downe's, which is in flower at the same time. I agree with "J. T." that it is of vigorous constitution and a good bearer, producing splendid bunches and berries with a Muscat flavour. What few berries can be kept remain plump up to February. I have never, however, succeeded in sending a presentable bunch to table; more than half the bunch has to be cut during the ripening of the part which remains, being so much affected with spot, or something in appearance more like a scorch, but scorch it cannot be, as the foliage is so dense. This spot, as I shall call it, commences just as the fruit is swelled-off to its full size, and goes on more or less until fully half the bunch is gone. I tried the Vine pots, and had good bunches and berries, but the result was the same as in the case of the Vine which is planted in the border. I have it planted on a south-east wall outside, where it is equally vigorous and prolific; but our summers have not been so warm during the last two years. In 1870 I had one tolerable bunch from outside, which was nearly ripe and quite eatable.

I would not recommend this Grape to anyone. We retain it simply because we can make up a dish of the bits of bunches to go along with Lady Downe's for very late use. Muscat of Alexandria, if properly managed, will keep to go with Lady Downe's, and for size of bunch and berry we have no Grape to equal it. Like Mr. Douglas, I cannot see any improvement in our new late Grapes. Give me Black Hamburgh, true, and a Muscat of Alexandria; I would grow nothing else to any extent. I could enumerate many meritorious Grapes; but if I only had space for two Vines, the Black Hamburgh and Muscat of Alexandria would be the two.—C. M. McCrow, *The Gardens, Nash Court, near Faversham, Kent.*

METROPOLITAN FLORAL SOCIETY.—Will you allow me to announce to our members, and to florists generally, that the autumn Show of this Society will be held in one of the oldest haunts of the older generation of florists now rapidly passing away—the Royal Surrey Zoological Gardens, and that the schedule will be more liberal than we have been enabled to offer for the last three years, that the competition will be exclusively for flowers, and that every effort will be made to make it a success. The days fixed for it are August 26th and

27th. Schedules will be ready in a few days, and I shall be happy to answer any inquiries directed to me on the subject.—D., Deal.

A VISIT TO THE ROSES AT CHESHUNT.

HAVING often been invited to pay a visit to Cheshunt, I have at last been able to accomplish this, and found the last week of June very favourable to my purpose. Shoreditch Station is not a palace of crystal, nor is the Lea Valley the perfection of the picture-que; however, the happy owners of land, generally rented at £5 an acre, are probably able to view this latter with considerable complacency; as the Scotch sometimes say, "She is better than bonnie." Cheshunt is advertised as thirteen miles north of London; it is certainly a good half-hour off by the Great Eastern Railway. The Cheshunt Station is a mile from the nurseries, but the lover of antiquity will do well to stop at the Waltham Station just before it. The lovely Eleanor's Cross, very near to the Waltham Station, both for its exquisite beauty and good preservation, would of itself well justify and repay a pilgrimage. Passing the ancient "Hostellerie of y^e Foure Swannes," dating from 1260, as its quaint old signboard, stretched across the road, informs all men, and leaving on the right Mr. W. Paul's well-known and famous nurseries, Paul & Son's at Cheshunt is reached in about one mile and a half.

The first sight on entering is singularly interesting to a rosarian beginning to advance in years; there is the original guinea plant of Maréchal Niel as first sent out, and, as a companion plant, the first Charles Lefebvre; grand old Briar stocks they have, but are evidently beginning to feel their years and hard service. After this, seventy acres under spade are more or less open to the footsteps of the inquiring visitor. It will only be possible to mention what, perhaps, is the most striking in the Rose districts. Having been sent by the courteous proprietor to the principal nursery ground, appropriately called Roselands, I found myself at once in a bewilderment of beauties. Such growth and such grandeur are not often to be witnessed. The Manettis were hardly out, but the plants appeared of extraordinary vigour; while, as for those on Briars, they were enough to send the amateur home despairing for ever! It was, however, some consolation to reflect that if Roses did not do well in the rich loam of the Lea Valley, on the banks of the New River, and with any quantity of manure at their service, they would be little likely to prosper on any other portion of our planet. But there they are, and will soon be telling their own tale in "the boxes." A Rose is not really understood until it has been seen growing in some quantity, all the best are found under these conditions at Roselands: the dignified and fastidious Marie Baumann appears there in the very rudest health, and really not much smaller than that monster Paul Neron. It might be invidious to mention names where all are so magnificent, but I may remark that Etienne Levet, President Thiers, and Annie Laxton (the last a considerably improved Jules Margottin) are fully bearing out the good opinions of last season.

Having returned, and partaken of Mrs. Paul's graceful hospitalities, I was conducted by the proprietor himself through the home garden, and especially over the seedling beds, a part interesting above all else to the experimentalist. The number of seedling Roses is very considerable. It was impossible not to look with deep interest on the collection of possible glories and beauties before us. Here, too, we moralised, how many embryo Maréchal Niels and Devoniensises may have perished, victims of too severe winters! As Gray remarks of another place—

"Some village Hampden, that with dauntless breast
The little tyrant of his fields withstood;
Some mute inglorious Milton here may rest,
Some Cromwell guiltless of his country's blood."

However, the actualities are sufficiently striking. Several still unnamed seedlings were shown to me of robust growth and most brilliant colouring, and which will probably be hereafter heard of; but the three that have been lately named and selected are unquestionably the present pride of the garden. Reynolds Hole and Wilson Saunders are both very good reds, the latter a seedling from Charles Lefebvre, but of sufficiently distinct foliage, and likely to be very valuable in its class; the former is evidently a great favourite with its owner; I did not see blooms which could supply an opinion. But the Rose of the season will certainly be the Cheshunt Hybrid. It has already received high commendation in your Journal, and is every way calculated to win golden opinions. It is very hardy,

very vigorous, large, of a brilliant colour—in fact, almost a Maréchal Niel among the red Teas, and a Rose which, I suspect, soon no Rose garden will be without.

Passing on through the new Rhododendron garden, which would excite high admiration, had the Roses any to spare to it, we then visited the Roses plunged-out in their pots, and a wonderful blaze of colour and brightness they afforded; the pegged-down Roses are also in very fine order. The Roses under glass had been brilliant, and in one instance showed a Rose hep of Madame Falcot, which had been fertilised from a bloom of Camille de Rohan, a combination which, if it succeed, will be one of rare excellence.

Returning home the happy owner of an instantly purchased Cheshunt Hybrid, even at the formidable price at which alone, for the present, it leaves Cheshunt, taking one mere lingering look at the sweet Queen Eleanor, and returning with rather more rapidity to Shoreditch, I escaped the varied perils of that peculiar locality, some day to tell again of rosarian rambles.—A. C.

VERONICA RUPESTRIS.

A REALLY good blue is a colour more frequently met with among the flowers of hardy herbaceous plants than those of tender exotics. Even bedders-out are not over-well supplied with good clear blues; it is true Lobelias come in very well, but Verbenas do not approach the true tint, and exhibition plants are very deficient in this colour. Hardy herbaceous plants, however, present us with many examples. The Campanulas, Veronicas, Delphiniums, Aconitums, Violas, and others give us many splendid blues, and a good clear blue, like a bright scarlet or a clear yellow, is at all times acceptable. Such an one is the subject of the present short notice.

Veronica rupestris, a trailing plant of low growth but compact habit, is certainly one of the most showy of its family, and as hardy as a Buttercup. It has not been so long amongst us as many neglected hardy plants, having been introduced during the last twenty years, and it is a most desirable addition. Its foliage is small and willow-shaped; habit spreading, and the branches all disposed to root as they lie upon the ground. Each shoot as it points upwards is divided into innumerable spikes of bloom, rising 6 inches or more high, while their bases are within an inch or so of the ground. The thickly-set spike of blossom is of a very bright blue with a small spot of white in the centre, which becomes larger as the bloom advances, being but little seen at first, so that the impression is that we are looking upon a clear bright blue-flowered plant; but I do not think the presence of white an objection, as it, perhaps, imparts brightness. The number of flower-spikes is such as to completely cover the space the plants occupy, and masses nearly a yard in width have a gay appearance in May and June.

Veronica rupestris is, perhaps, a little too late for spring bedding, yet old plants of it are in full bloom before *Viola cornuta* growing under similar circumstances, while it is much more dwarf. I have been thinking of trying it in beds for late spring decoration, as it can be so successfully transplanted, and is so accommodating as to site, &c. Perhaps, however, the best of all places for it is the rockery, to which its spreading habit seems so well adapted, and in such a position it cannot be otherwise than at home. Certainly no more becoming plant could be employed either there or in the mixed herbaceous border, to which a few plants near the front give a brightness which it is difficult to equal, even in the flowery month of May.—J. Roxson.

ROSE BARONNE DE MAYNARD.

I AM pleased to see the Rev. W. F. Radclyffe speak so well of this pure and useful variety. As a general garden decorative Rose it quite heads the list, in my opinion, amongst whites. It is an easy and free grower, is less susceptible of Rose ailments than many of its neighbours, and is an exceedingly free bloomer. It ought to be in every garden where Roses, and especially white ones, are cherished; and who would not cherish them, and who does not covet them, both to tone down and bring out the richer colours by the force of innate purity and vivid contrast?

My attention was first drawn to this variety by my employer, who takes the opportunity of seeing all old and new Roses both at the principal exhibitions and in many gardens. He has long pronounced it the best white Rose, and up to the

present time stands by it firmly, and I as firmly believe he is right. It is not, however, an exhibition Rose. It lacks the build and cup-like contour to take a place amidst a group of perfect cut blooms. Plant it, however, in the garden, and a lady armed with a pair of scissors, and engaged in decorating her room, will never pass it by. On that recommendation I am content to leave it, because it shows as plainly as anything can do, that a garden is incomplete without a plant or plants of Baronne de Maynard, the best early and late white Rose. I should like to see a large bed or hedge of this and, say, Général Jacqueminot alternately planted. The effect could not fail to be exceedingly fine.—J. WRIGHT.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY'S SHOW.

THE Edinburgh Midsummer Show is always an interesting one, and on this occasion the display in the Music Hall, George Street, on July 2nd, was general and excellent. Plants were somewhat deficient, but the shortcomings in this respect were amply compensated for by the rich assortment of fruit. At no corresponding show have we had the pleasure of seeing such fine collections of Grapes; the highly-finished, well-ripened bunches were superb.

For the collection of six sorts of fruit, Mr. P. Stewart, gardener to Charles Tennant, Esq., The Glen, was first with two fine Queen Pine Apples, two splendid bunches of Black Hamburgh, some excellent Peaches, Nectarines, Plums, and Figs. Mr. Fortune, gardener to J. Jardine, Esq., Castlemilk, Dumfries, was second with some Pines inferior to those in the first-prize collection, good Peaches and Black Hamburgh Grapes, a dish of the fruit of *Musa Cavendishii*, Garibaldi Strawberry, and Munro's Little Heath Melon; of the latter Mr. Fortune showed four fruit weighing 22 lbs.

For two bunches of Black Hamburgh Grapes Mr. Stewart was first with perfect examples. The second-prize bunches, from Mr. Neil, gardener to Mrs. Erskine Wemyss, Wemyss Castle, Fife, were much larger in the berry, but not up in colour. For two bunches of Muscats, Mr. McConochie, gardener to A. Smollet, Esq., Cameron House, Dumbarton, was first with fine bunches rather unripe. A fine bunch of Muscat Hamburgh and one of Black Prince from Mr. Stewart were first for two of any variety; Mr. Laing, Pitcairrie, Fife, coming second with Madresfield Court, small in bunch, but large and plump in berry. For two of any sort, white, Mr. McConochie was first with fine Buckland Sweetwater; Mr. Laing second with Golden Champion. These were not quite ripe, but otherwise perfect, exhibiting no defects whatever. Mr. Stewart was first for a single bunch of Black Hamburgh, and Mr. Laing second. In the class for flavour Mr. Neil was awarded the first prize for a thoroughly-ripened bunch of Black Hamburgh. Mr. Fortune being second with the same variety. Chasselas Musqué from Mr. McConochie, and the same from Mr. Laing, took the prizes for white Grapes.

Some fine Queen Pines were exhibited by Mr. Stewart, who also obtained the first prize for a single fruit. Melons were numerous. Mr. Laing came first with a fine Queen Emma, Mr. Shaw, Donisla, Newington, second. For six Nectarines Mr. Gibson, Vogrie House, showed some finely-coloured fruit of the Newington. The first-prize Bellegarde Peaches, from Mr. Tait, Calder House, were also fine. Excellent Prince of Wales Strawberries came from Mr. Fairgrieve, gardener to the Duke of Athole, Dunkeld, and from Mr. Smeal, Meadow House.

On the two principal tables in the centre of the Hall were staged the twelve stove or greenhouse plants in competition for the ten-guinea prize given by Messrs. T. Methven & Sons, nurserymen, Edinburgh. Only two lots were shown, the first coming from Mr. Paterson, Milbank, and the second from Mr. Currie, Salisbury. Mr. Paterson's group contained a magnificent specimen of *Onidium sphaclatum*, the pretty *Erica Bothwelliana*, *E. Bothwelliana alba*, *E. tricolor Wilsoni*, *E. Antoniana*, *E. Paxtoni*, *Dracophyllum gracile*, a large plant of *Latania borbonica*, and a beautifully-flowered plant of *Disa grandiflora*. Mr. Currie's collection contained a unique specimen of *Anthurium Scherzerianum* with forty-five fully-expanded spathes, *Cypripedium barbatum* with an immense number of blooms, a fine plant with six spikes of bloom of *Dendrobium densiflorum*, *Lælia purpurata*, *L. purpurata var.*, a large plant of *Statico profusa*, and the curious spiny *Astrocarum mexicanum*.

Ferns, British and exotic, were well represented from the fine collection of P. N. Fraser, Esq., Cannonmills Lodge, trees from Mr. Currie, others from Mr. Paul, Gilmore Place, and Mr. Weatherston, Restalrig. Pelargoniums were not up to the mark in form and profusion of bloom. Some good Tricolor and white-edged *Geraniums* were shown by Mr. Kennedy, St. Margaret's Tower, who had the first prize in both classes.

The nurserymen's collections filled the greater part of the Hall; that from Messrs. T. Methven & Sons contained some lovely *Begonias*, *Marantas*, *Crotoms*, *Dracenas*, *Ericas*, *Azaleas*,

&c. Messrs. Dickson & Co., Waterloo Place, had also a fine collection of stove and greenhouse plants, among which were some beautiful *Caladiums*, *Agaves*, *Pandanuses*, a magnificent plant of *Statico Clarkii*, &c. The Lawson Seed and Nursery Company (limited) had the orchestra tastefully adorned with large specimens of *Coniferæ*, *Palms*, *Picuses*, and probably the finest plant of the lovely *Adiantum farleyense* that has ever been shown in Edinburgh. A large and varied group of succulents from the same firm was a great centre of attraction and note-taking. These plants are quite admissible in the choicest collections, and we hope to find a special prize offered for them in the Society's next arrangements.

Cut Roses were shown in high condition, such as we would have looked in vain for in the memorable 1872. The finest blooms in the Hall came from Mr. Hugh Dickson, Belmont Nurseries, Belfast. His stand, containing forty-eight, was magnificent; Duke of Wellington, Alfred Colomb, La France, Baroness Rothschild, Camille Bernardin, Duke of Edinburgh, François Fontaine, Lyonnais, and Marquis de Castellane were gorgeous, though not exceptional. Second to these in merit, but first for the stand of twenty-four, were those shown by Mr. McMillan, Broadmeadows, Berwick; especially fine amongst these were *Souvenir d'Elise*, *Adam*, *Alba Rosea*, and *Devoniensis*, all Teas. Amongst Hybrid Perpetuals were *Marquise de Castellane*, *Vicomtesse de Vesins*, and *Jules Margottin*. For twelve, Mr. McMillan secured the first prize, Mr. Armour was second, and Mr. Fairgrieve, Dunkeld, third. Mr. McMillan was first for six cut blooms, also for twelve splendid Teas of the following varieties: *Madame Willermoz*, *Madame de Tartas*, *Madame Gaillard*, *Comtesse de Brossard*, *Madame Falcot*, and *Niphotos*. These blooms, as well as all the others shown by Mr. McMillan, were very much superior to any exhibited in these classes.

Messrs. Downie, Laird, & Laing exhibited a very large fruit of a new Cucumber named Birthright, said to be very prolific, and a fine winter sort. Nothing could have been possibly finer than the half-dozen fruit of this variety shown by them at the show in December last.

First-class certificates were awarded to Mr. William Young, 33, South Bridge, Edinburgh, the enterprising acting Secretary to the Society, for two new Carnations of the *Souvenir de Malmaison* kind. That named Young's Rival is a massive bloom of a beautiful rich pink colour; the other, Young's Beauty, is of equal form, with a light ground distinctly striped with deep pink. Both are highly fragrant, and quite acquisitions.

SCOTTISH PANSY SOCIETY.

THE annual competition was held in connection with that of the Royal Caledonian Society. Much interest was manifested in this department, especially by amateurs. Hundreds of unnamed blooms of all known shades and markings were shown by nurserymen, gardeners, and amateurs. Messrs. Dickson & Co., Waterloo Place, Edinburgh, who have done much to improve and popularise these flowers, occupied the first place. Amongst their twenty-four first-prize dissimilar blooms, Dickson's Golden Gem, Snowflake, Canary, Aman, Magnifica, Butterfly, and *Stricta alba* were especially fine. In the open class for the best white ground, Messrs. Dickson & Co. were first with the lovely form of Jane Grieve; for the best yellow ground, Mr. D. Kerr, gardener to Lord Shand, Glenclorse, with Robert Burns. For the best dark self, Mr. D. Taylor was first with the Rev. Mr. Morrison. Snowdrop was the finest white self, Cherub the finest yellow; and In Memory, from Messrs. Dickson & Co., the finest blue. Jane Grieve, shown by Messrs. Dickson & Co., was awarded a first prize as being the best bloom in the room. Messrs. Dickson & Co. obtained the silver medal as taking the greatest number of prizes. Other successful competitors and medal-takers were Mr. Beveridge, Portobello; Mr. Mitchell, Corstorphine; Mr. Cuthbertson, Corstorphine; and Mr. Fairgrieve, Dunkeld.

TUNBRIDGE WELLS HORTICULTURAL SOCIETY'S SHOW.

ONE of the greatest events of the year at this place is the annual Flower and Fruit Show. A stranger visiting the town could not fail to be apprised that something of importance was taking place, and that the centre of attraction was the Calverley Hotel and grounds opposite the station on the South-Eastern Railway. To this spot a little before three in the afternoon people are flocking in crowds, and at the grand entrance to the Hotel there is much difficulty in obtaining admission, owing to the pressure. Thanks to the indomitable perseverance of Mr. E. F. Loof and an excellent working Committee, this has become one of the best country shows in England. Excepting on the occasion of the distribution of Messrs. Veitch's prizes at the Royal Horticultural Society's Show on the previous Wednesday, we have not seen such an exhibition of Grapes this year; but at this Show, held on Friday, July 4th, other sorts of fruit were exhibited in proportion, and of excellent quality.

The principal exhibitors of Grapes were Mr. J. Douglas, Loxford Hall Gardens; Mr. H. Spencer, gardener to T. Holman, Esq.; and Mr. G. Halliday, Bletchingley. Black Hamburgs were well coloured and ripened, and Golden Champion as fine as ever it has been exhibited. The best Pines were sent by Mr. C. Rye, of Tunbridge, and Mr. G. Ward, of Bishop Stortford. The best Strawberries, an excellent dish of Sir J. Paxton, were sent from Dr. Newington's gardens, Ticehurst. Collections of fruit were not shown so well as the other classes. Mr. T. Hopgood, gardener to Julian Goldsmid, Esq., exhibited the best dishes, quality and arrangement being taken into account.

Tunbridge Wells is strong in Cucumbers. No less than thirty brace were staged in competition. Mr. J. Staples, gardener to Mrs. Candy, showing a brace of a fine white-spined variety, and taking the highest award.

In stove and greenhouse plants, fine-foliaged plants, Ferns, Lycopods, &c., there was strong competition. The best stove and greenhouse flowering plants were sent by Mr. W. Knight, gardener to F. D. Shadwell, Esq., Fairlight. The intense crimson of his *Kalosanthes coccinea* and the deep blue of *Statice imbricata* were remarkable. Fine-foliaged plants of considerable merit were sent by Mr. G. W. Jobson, gardener to W. H. Stone, Esq., Leigh Park, Havant; amongst them were fine examples of *Pandanus ornatus* and *Cordyline indivisa*.

Lycopods were really splendid, and the well-grown healthy plants of *Selaginella apoda*, *S. Lobbi*, *S. Martensii*, *S. formosum*, and *S. caesia* sent by Mr. H. Scammell, gardener to C. Reily, Esq., Nevill Park, secured for him the first prize. We have not space to enumerate all the prizes, nor to describe the handsome specimen Ferns nor the *Fuchsias*, fifty specimens of which were arranged down the centre of the large tent. We have seen very good *Oreibids* exhibited here, but on this occasion only one poor collection was shown.

The cottagers are not forgotten at Tunbridge Wells, and we must say that the prizes awarded to them were well earned, their productions being of a very high order of merit. A series of prizes are also given for the best-managed garden, the value of which in the aggregate amounts to upwards of £15, and no less than twenty-one competitors contested them. The competition is confined to a radius of five miles round Tunbridge Wells. Mr. A. H. Bull had in this instance the honour of being in the highest position, and was awarded the first prize of £4.

ROYAL HORTICULTURAL SOCIETY'S ROSE SHOW AT BATH.

(Continued from page 6.)

In the class for thirty-six Mr. H. Grant was equal first with Mr. Baker, and had Cloth of Gold, Madame Charles Crapelet, Pierre Notting, Madame Marie Crédde, Madame Boutin, La France, De voniensis, Charles Lefebvre, America, Ferdinand de Lesseps, &c. The Rev. J. B. Cunn was second.

New Roses did not come out very strongly. Only one box of blooms was shown by Messrs. Paul & Son; it contained Madame Lacharme, a nice bloom; Bessie Johnson, Reynolds Hole (a seedling of Mr. Paul's), very dark; W. Wilson Saunders, another seedling remarkably like Charles Lefebvre; Cheshunt Hybrid, Annie Laxton, and some others not very striking. In the prize for the best twelve blooms of any Rose of 1872-73, the prize was given to Annie Laxton, a remarkably fresh-coloured flower, and exhibited by Messrs. Paul & Son; second to Mr. Cranston for André Duand, a light-coloured flower, style of Baronne de Rothschild. Messrs. Paul also exhibited fine blooms of Cheshunt Hybrid, and Mr. Cooling obtained third for Abbé Bramet—not that this is a better Rose than Cheshunt Hybrid, but the same exhibitor cannot take more than one prize in each class; I regard it as a rough high-coloured *Géant-des-Batailles* style of flower. In the class for six blooms Messrs. Paul & Son were first with Annie Laxton, Mr. Cranston second with Madame Bellon, and Mr. Cooling third with President Thiers. For two new Roses in pots sent out by English nurserymen since 1871 there was no competition, Messrs. Paul & Son being the only exhibitors; their plants were Princess Louise and Cheshunt Hybrid. Altogether it was a very pleasing exhibition, and my chief regret was that I could not linger over it.—D., Deal.

OPENING OF THE PUBLIC PARK AT WARRINGTON.

THE formal opening of Bank Hall and Gardens as a Town Hall and Public Park, was the occasion of a great demonstration in Warrington on June 20th. The demesne which has passed into the hands of the Corporation in trust for the people of Warrington belonged to the Patten family, a time-honoured name; and the Right Hon. J. Wilson-Patten, M.P., in placing within the reach of his fellow-townsmen the opportunity of acquiring so desirable a property, has only afforded another instance of his desire to act the part of a real benefactor.

The Park has many advantages over a new place. It has

ready-grown trees and shrubs, three-quarters of a century old, which few new parks can boast. The trees are not so numerous as they were twenty-five years ago; several outside the gardens have been cut down to make room for buildings, and consequently there is not the same picturesque scenery there was formerly. But to compensate for this, the growth of flowers has been increased, and new walks so arranged as to make the grounds appear larger than they really are; fresh openings have been made to give more effective scenery within the walls. Rhododendrons flourish, and some are large and some very old, one still standing which the late Mrs. Wilson-Patten, mother to Col. the Right Hon. J. Wilson-Patten planted, was the first Rhododendron grown in that garden. Although the grounds are laid out with taste, it is capable of modification to make it more advantageous as a public park. Viewed from the front of the Hall is a lawn belted on each side with trees; the east, or side towards the town, is the front entrance through an avenue of trees, chiefly English Elms, some very old. On the west side is another drive lined with trees not so old as those on the east side. Looking from the front door over Arpley meadows, which lie low, across the Mersey to Hill Cliff and other rising ground in Cheshire, we see a nicely wooded landscape, dotted with houses in the distance, but the view is somewhat deteriorated by the railways. On the west of the Hall is the grass land, belted north and south with trees, but open to the west against several works. North of the Hall is the garden, and from the new council-chamber is a view over a close-mown lawn, surrounded with large Rhododendrons, interspersed with trees, flower beds, walks, and a serpentine sheet of water, with a rustic-looking temple at one end, the whole being enclosed by a wall. The flower beds are filled with ornamental-foliaged and flowering plants, and the number used for this purpose is over 9000.

Banquets, illuminations, and processions rightly attended the auspicious event, for auspicious it is for any town to have in its vicinity such a people's park and gardens. Among the processions was one that has endured for many centuries, and was one of the most interesting—"The coronation of the Bonnie Queen of May," which took place in St. Elphin's Park in the evening, before an immense concourse of people. Shortly after six o'clock the procession, headed by the band of the Runcorn parish church, marched to a hollow part of the Park, where there was erected a temporary platform, with two chairs thereon, for the accommodation of the King and Queen. This was a most advantageous position, as the spectators could stand on the rising ground and without unnecessary crowding have a full view of the scene. The procession presented a very imposing spectacle. The King, Master James Singleton, was attended by Master W. Lilley, the crown-bearer, and Master Fred. Wood, the Grand Duke; while the Queen was accompanied by her train-bearers, Miss Edith Broadhurst and Miss Emily Boardman, and her maids of honour. The Queen, a pretty intelligent-looking girl, was attired in a snowy-white muslin frock, stockings and shoes of equal whiteness, a scarlet cloak trimmed with white fur, and a white rosette for a head-dress. The other girls were dressed in white frocks trimmed with blue and pink, and each wore a wreath of flowers on the head. The King wore a crown on his head, carried a sceptre in his right hand, his feet were covered with patent leather slippers with yellow buckles, and over all he had a long robe of ermine velvet trimmed with white.

The boys were neatly attired for the occasion, and several of them carried a small tricoloured flag. The girls who belonged to the Mount Schools, were under the direction of Miss Shaw, Miss Hankey, and Miss Bennett; while the boys were under the superintendence of their master, Mr. Dewhurst, of the National School, Church Street. On arriving at the halting point, the children were arranged in a circle around the throne, upon which the King and Queen took their seats. Immediately on getting into position, Master Singleton raised himself to his feet, swayed his sceptre with an air of diffidence, and in a clear and distinct voice addressed his "subjects" in the following words:—

My Loyal Subjects,—By God's providence we are met to celebrate another anniversary. To-day is a doubly auspicious one, as I, the King of your schools, am here to crown my Queen before you. First let me congratulate you on taking part in this morning's ceremony. You have, by the munificence of the Right Hon. Colonel Patten and George Crossfield, Esq., become possessed of a Town Hall and Park. May you live long and enjoy them [cheers]. Our worthy Mayor, too, deserves a cheer [cheers]. In our little scholastic spheres vast improvements have been made for our benefit, and I trust we are wiser and better than when we last assembled [cheers]. And now, my loving subjects, I crown her (whom you have chosen for diligence and good conduct) my Queen, and may peace and happiness still reign in our little dominion [cheers].

The coronation was now completed, and their majesties resumed their seats with becoming dignity and grace. The King retained the sceptre in his right hand, while his consort held a white pocket-handkerchief in her right hand and a scarlet Geranium flower in her left. The beauty of the scene was now at its climax. There sat enthroned before you the finely-robed King

and the newly-crowned Queen with obedient attendants at their feet; encircling them were a lot of pretty boys and girls with countenances beaming with happiness and delight; and the higher ground for some distance was covered with spectators of all ages and sizes, amongst them being a large number of ladies whose gala attire dazzling in the setting sunshine, contributed greatly to the gaiety of the scene. The coronation was followed by some singing, the songs selected being the following:—"Long may Life and Health be Spared Us," "Away, Away, to the Woods Away!" "Harvest Time," and "Home, Sweet Home."

Three cheers were then given for the rector (the Rev. W. Quekett), Mrs. Quekett, the curates (the Revs. J. Tedman and J. P. Petty), the churchwardens and sidesmen, the subscribers to the schools, and for the King and Queen. Their majesties acknowledged the compliment with a gracious bow.

ROYAL BOTANIC SOCIETY'S SHOW.

JULY 9TH.

THE last Exhibition for the season was held yesterday, and we have no hesitation in saying that it was one of the poorest ever witnessed at the Regent's Park. Hitherto we have been accustomed to have a fine display of fruit at the July Show—fruit there was none. Its place was usurped by an exhibition of table decorations, very meritorious it is true—light, airy, and elegant, with but few exceptions; but we are sorry to see such things encouraged at the expense of cultural skill. Flowers are beautiful to the eye, many of them delicious in scent, but fruit combines with these qualities flavour as well; it is an important article of food, and one which greatly contributes to the preservation of health. Surely something should be done by our leading societies—in fact, by horticulturists generally, to bring back fruit from the cold shade of neglect with which it is overlaid. The Veitch prizes given last week were a step in the right direction, but we must not leave these things to individual effort—united action should be taken. After all, the most beautiful table-arrangement is but an adjunct to the viands, and these, whether fish, flesh, fruit, or vegetable, must be produced, and it is more to the national benefit that they should be produced well and abundantly than that such undue prominence should be given, and so much time and money expended on the passing fancy of the hour. Many a gardener would rejoice at their restriction within the narrowest bounds, for the demands made in many instances on the gardener for time and flowers for these decorations are something enormous. Whilst making these remarks we by no means wish to advocate the neglect of the elegancies of the table, but we merely utter a protest against their encouragement at the expense of legitimate horticulture.

Stove and greenhouse plants in flower were but few, and on the whole not remarkable for quality. Mr. J. Wheeler, however, exhibited a good half-dozen in the amateurs' class, whilst in that for nurserymen Mr. Williams, of Holloway, to whom the Show was indebted for most of its best features, contributed a fine specimen of *Acrifolium odoratum* majus, *Cypripedium barbatum* superbum, and *Anthurium Scherzerianum*, the last somewhat tarnished.

Of fine-leaved plants Mr. Bull, of Chelsea, had a very fine *Cycas revoluta*, a large *Latania borbonica*, *Draecena lineata*, and a fine *Eucalyptus*; he likewise exhibited the best four *Draecenas*—viz., fine plants of *Shepherdia*, *Cheloni*, *Regina*, and *grandis*; Mr. Bester, of the Pine Apple Nurseries, and Messrs. Carter & Co. having the next best. Among *Caladiums* we noticed excellent plants of *Canartii*, *Chantini*, *Max Kolb*, and others from Messrs. Jeal, Ritchie, and G. Wheeler; also good *Canas* from the last-named and Messrs. E. G. Henderson. *Palmæ* came from Mr. Bull, Mr. Croucher, gardener to J. Peacock, Esq., Hammersmith, and Mr. G. Wheeler; and a fine group of six exotic Ferns from Mr. Williams. Of hardy Ferns good collections were exhibited by Messrs. Ivory, James, and Wheeler.

Of *Fuchsias*, Mr. Walker, gardener to H. Atkinson, Esq., Acton, had fine specimens of *Rose of Castile*, *Reine Blanche*, *Compiègne*, and *Souvenir de Chiswick*, Messrs. Weston, Wright, and G. Wheeler also showing well. Mr. Turner, of Slough, sent a splendid lot of new Show *Pelargoniums*, most of which have been noticed before; *Protector*, *Ruth*, *Duke of Cambridge*, and *Prince of Wales* were very striking. Mr. Weston and Mr. Burley had good *Zonal Pelargoniums* in flower; and fine collections of *Tricolors* came from Mr. Pestridge, Cambridge, Mr. Turner, Slough, and Mr. Wright, Leam. An unfortunate accident happened to those of Mr. Turner, which caused their removal from the tent.

Messrs. Lane, Great Berkhamstead, exhibited in a collection of six hardy *Combers* nice plants of *Thymopsis dolabrata*, *Juniperus liberica* compressa, a very compact sort of erect growth; *Retinospora squarrosa*, very handsome; *Cryptomeria elegans*; *Retinospora leptoclada*, forming a lovely, bright green column; and *R. plumosa aurea*. The same firm also sent the only group of hardy evergreens that we noticed.

Among miscellaneous groups foremost must be mentioned those of Mr. Williams and Messrs. Robinson, consisting of *Orchids*, *Palmæ*, *Ferns*, and other stove and greenhouse plants,

that from Mr. Williams being especially remarkable for its number and excellence. From Messrs. E. G. Henderson came a group of *Tree Carnations*, *Tricolor* and other *Pelargoniums*, *Coleuses*, &c.; from Mr. Ware, Pentstemonus, *Delphiniums*, bedding *Violas*, and blooms of *Carnations* and *Picotees*; from Messrs. Carter & Co. a pretty lot of *Lobelia* named after the three Christian graces; and from Messrs. Veitch, splendid boxes of cut blooms of *Roses*. For three trusses of forty-eight varieties Messrs. Paul & Sou were first, Mr. Turner second, both exhibiting remarkably fine trusses; and for yellow *Roses* Mr. Webb, of Reading, took the first place with *Maréchal Niel*.

Botanical certificates were awarded to Messrs. Veitch for a Japanese *Elaeagnus* with pale rose-coloured fruit; to Messrs. Carter for *Campylobotrys Ghiesbreghtii variegata*, and *Lilium Kramerii*; to Mr. Croucher for *Agave Verschaffeltii variegata*, *A. Corderoyii*, and *A. perbella*; to Mr. Williams for *Phaius Marshallii*; to Mr. Ware for *Acantholimon venustum*; and to Messrs. Dixon & Co., Amhurst Nurseries, also to Mr. Forsyth, Stoke Newington, for *Lobelia pumila grandiflora flore-pleno*, which has been reported upon before as a fine, compact, double blue variety.

OLD DOUBLE WHITE ROCKET.

SOME inquiries having been made of late about this favourite of olden times, and as it happens to be in flower at present I may add that those who have been looking far and wide for this now almost-lost ornament of the gardens of our forefathers, will, on finding it, be somewhat disappointed, for it is certainly inferior to the tall Rocket for the generality of purposes for which a white Rocket is wanted. Dwarfier it certainly is. The spike I send you was taken from a plant growing in good ground, and was fully a foot high—about half the height of its taller brother. Its foliage is also smaller and of a brighter green, less inclined to be downy; but in other respects the plants are much alike, except in one point, and that to me an important one—the taller one is by far the easier to grow and manage. The dwarf one has a tendency to die-off at all times of the year, even sometimes when just throwing up its flower-stem; and it is, as most sickly plants are, of such uneven growth, that I cannot recommend it with so much confidence as I do the taller kind. Perhaps the soil here may not suit it; or as a variety, which I presume it must be considered, it is worn out. Certainly it is not very common, for after having lost sight of it several years before the first Reform Bill became law, I did not see it again until, some five or six years ago, I met with it in a very old-fashioned garden in Lancashire; but I am somewhat disappointed in it, and cannot give it that character for general utility I would like to do. As a white it is more pure, perhaps, than the tall kind, quite as double, the flower-spike more densely set with flowers, and a prettier foliage decks the stem, but the tendency of the plant to die-off unexpectedly counterbalances these advantages in my idea. Perhaps, however, in the fine sandy soils that margin the coasts or are found in many inland districts, it may do better. I think I have been told of its doing well about Preston in Lancashire, but I may be wrong. Perhaps those having it in a thriving condition will tell us its whereabouts and other particulars.—J. ROSSON.

AMERICAN WILD PLUMS.

A WRITER recently, when giving an account of his travels in a region called Kansas, or Arkansas, states that an arid sandy desert in that part of the world produced in great abundance a Plum tree not so large as a Gooseberry bush, bearing very large and luscious fruit. I want to learn if any such desirable shrub is known to our horticultural experts. Is there any account or mention of it in any authentic work on American trees, if there be any such book? Without doubting the veracity of the writer, "E. A. C.," I have often been struck with the fact that when travellers stumblé upon some wondrous novelty a long way off, by some unaccountable neglect they omit to bring a specimen home or seeds thereof. The introduction of such a plant would be a small fortune to the discoverer, since, if not hardy enough for out-doors, it would obviously be specially adapted for an orchard house, now so common. I have no doubt that there are yet many wild fruits in the American wilderness which might be successfully introduced here.

I enclose a small twig of *Shepherdia argentea*, now laden with flowers; each, as you will see, is trumpet-shaped, like a Cowslip. As there is no thorn or prickly spine on it I cannot see the use of it as a fence. It is so brittle, that in trying to take off a twig I broke off a large branch. Would you oblige me by stating what sex you think my plant is, and how I am

to get hold of the opposite one, so as to raise a breed of "Buffalo Berry?"—JACKSON GILLEBANKS.

[Your plant is bi-sexual, and would be fruitful under favourable circumstances.—Ers.]

SHADES AND SHELTERS.—No. 2.

I now come to the second part of my subject—viz., shelters or protections against excessive rains, winds, frosts, &c. I do not include glass shelters or wall copings, but merely some of the common means employed to protect garden plants and flowers that are cultivated in the open air.

The fickle climate of this country necessitates the use of many things for protection, and it often happens that the simplest means saves a crop from entire destruction by frost. What would gardeners do without Fern fronds, dry litter, or fresh straw or hay? Either of these materials when scattered thinly over Gooseberry and Currant trees, early Potatoes, Peas, Kidney Beans, salading, and other tender subjects, will do wonders in the much-dreaded spring frosts. The object to aim at is to keep a stock of these things in hand, and when they are wanted the work of applying them is trifling. Then there are branches of evergreens not to be despised as a means of shelter. They can be used in many ways, particularly among bedding plants at the time of planting-out. When a bed is finished stick the branches among the plants; they greatly shelter these from cutting winds and hoar frosts. I do not think it safe to bed-out without this precaution, for if frosts and winds do not prevail the branches are a protection to the plants in the change they undergo. These branches, too, or Fern fronds and straw, may be put on to wooden frameworks of different sizes, to be used as shelters for any tender subject as circumstances may require. Lengths of netting, frigi domo, or canvas may be likewise stretched on a slight framework to be used in a like manner, or for fruit trees against walls. Any material, however, that will admit a sufficiency of the rays of light for the plant's progress is much better than anything causing too much darkening.

Fig. 5.

A very useful fruit-tree protector is that shown in *fig. 5*. It is a very light framework of deal or other wood. The two upright pieces have small cross-bars of the same material fixed into them. To these bars is threaded a very thin layer, two or three straws thick, of clean straight straw; it is cut off even at top and bottom, is made to any height required, and is set into the ground in front of the tree it is intended to protect. This is not put forward as the only means of fruit-tree protection, but it is worthy of more general adoption. When used for wall fruit the top of the uprights, *a, a*, go just under the wall-coping, and the bottom part from a foot to 18 inches from the

wall. From 6 to 8 feet is a convenient width; two men can then put these shelters up or take them down very quickly.

Figs. 6 and 7 are a wall-shelter called the Waltonian. It is a framework of wood (*fig. 6*) made to span the top of a 9-inch wall $3\frac{1}{2}$ inches down, and has a projecting piece 3 inches from the wall, with an augur-hole at the end; these spanners are placed

Fig. 6.

Fig. 7.

at regular distances along the top of the wall, and the shelter-board, about 18 inches wide, is provided with iron hooks at corresponding distances, inserted as shown at *a*, thus taking the weight of the board and holding it in position. This shelter is easily fixed, and has proved to be remarkably efficient in throwing-off heavy rains, heavy dews, and for keeping-off hoar frosts while the trees are in bloom. After all danger is past the boards can be taken down as well as the wall-spanners, and put under cover.

Fig. 8 shows a means of protecting newly-planted trees from heat; it is simply straw or hay hands wound neatly round

Fig. 8.

the stem as high up as where the first branches diverge. Some first place a thin layer of straw round the body of the tree, and finish it off as shown in the woodcut. Such a plan as this is very suitable to apply to trees that happen to be planted late in the spring, or for such trees as are impatient of removal, as Hollies and Evergreen Oaks, and where they are particularly exposed to the action of the sun. I well remember once seeing two clumps of Sycamores planted on two mounds during March; a dozen trees were planted in each clump, but whatever happened to prevent, there was one clump

only with the stems covered with haybands as above described; and, strange to say, eleven out of the twelve grew, while only two out of the corresponding clump made a growth. Several others attempted to do so but died, and my impression at the time was, that if the stems had also been covered most of them would have lived. It is an excellent plan to assist plants to recover the effects of a removal, for it keeps the pores of the rind open for the absorption of moisture, and the bark plays its part in the elaboration of sap as well as the leaves. If dry weather set in after planting, these strawbands or protections should be frequently saturated with water, as well as the branches syringed with the garden engine or any other suitable contrivance for scattering water. Some planters fix a sort of collar round the stem at the top of the haybands, which, if close-fitting, serves to convey the water down between the stem and its covering. This is not a bad idea.—T. RECOM.

LETTERS FROM JAPAN.—LIFE IN THE INTERIOR.—No. 4.

Shisoko, near Toyahi, March 21st, 1873.

In my last letter to you, dated December 22nd, I intimated that some weeks would elapse before you heard again from me, as I was going into the interior, where there were no postal arrangements, and very imperfect means of travelling. But my silence has been much longer than I had anticipated, arising from causes beyond my own control.

You will be sorry to hear that I have been very ill since I left Tokio. I took cold, and have been laid up for seven weeks, and had to send for an English doctor from Yokohama, which is 275 miles distant from here. It has been a very severe attack of pleurisy on my left side. Until I got the doctor I adopted the best means I had, and with the help of God I am now nearly all right. I have had the greatest attention paid to me by the Japanese. I hope to get to Yokohama about the 1st of May, when I am to be removed to Simonsaki, which has the finest temperature in Japan. My Japanese interpreter has been most kind and attentive. I applied mustard and poppy poultices until I could get medical advice. The Japanese shot me two deer, as there was no other kind of European food which I could eat. I also obtained jellies in bottle from Yokohama. The doctor gives me credit for my treatment of myself. He said if I had not pursued the course I did I could not have survived, for he was three weeks in getting to me from the time when I sent a messenger in request of his aid.

I have made some "notes by the way" of the people and the country, but I do not yet feel strong enough to undertake the task of reproducing them in a form suitable for your columns.—J. TASKER POSTER.—(By the favour of the *Writer's* Father, Editor of the *Yorkshire Gazette*.)

THE FRUIT PRODUCE OF SPAIN.

In being summer time the beds of the rivers are quite dry; every streamlet and summer spring aids in supplying the irrigation canals. The force of the winter torrents is plainly evident from the terrible disturbance of their rocky beds; indeed, one of the most interesting features of these mountainous districts is the picturesque scenery of their river channels. In the valleys all is luxuriousness. Thousands of acres of Orange trees, under careful culture, displaying trees white with blossom, side by side with others bright with abundance of golden fruit. In other parts of Spain, as in Cordova and Seville, we have seen Oranges growing in profusion; but the traveller must visit eastern Spain to find the real Orange-growing country, which supplies our home markets so plentifully. Immense farms produce nothing but Oranges. Station after station along the railway marks the importance of the trade; trucks stand on sidings laden with boxes already packed, and carts discharge their freight of ripe fruit upon the ground in different station-yards. Hampers of delicious blossom await despatch to Barcelona and other places, for making the much-sought-after Orange-water of the toilette; all these evidences denote unmistakably that we are now travelling through the chief Orange-growing districts of Spain. To a visitor from the colder climate of England there is a special charm about such a country.

There are many varieties of Oranges, but the chief kinds for supplying the export market are the Bitter and Seville Orange. The former is largely exported for manufacture into marmalade, and large shipments are made to Scotland, particularly to Dundee. This Bitter Orange is also used for flavouring the

much-esteemed liqueur curaçoa. Orange trees flower in the spring. Neither the blossom nor fruit has a quick growth, and for many weeks the air is filled with the perfume of fulling blossom. In the evening the atmosphere is so impregnated with it that it becomes quite overpowering and sickening. The fruit commences to turn yellow late in the autumn, when that required for exportation is gathered, and after being wrapped in paper, is packed in cases. Oranges for home use are gathered as they are required; and be it observed, that to enjoy Oranges to perfection, they should be eaten fresh from the tree, and the most luscious fruit is that which hangs upon the trees until the new blossom appears. Throughout the Valencia districts we see new plantations of young trees and other plantations of various ages of growth. Trees begin to bear fruit about the sixth year; the fruit continuing to improve in quality for sixteen or twenty years, after which the Oranges degenerate, the rind becomes thick, and they are unfit for exportation to foreign markets, for which purpose only the choicest fruit is selected. Orange trees attain a great age, and still bear fruit. In the celebrated gardens of the Alcazar at Seville there are trees pointed out as having been planted in the time of Pedro the Cruel (1369), which are of immense size, and are still fruitful.

Expert chests contain from 700 to 1000 Oranges each, and are worth to the exporter from 25s. to 30s. each; they have open bars, so as to allow a circulation of air through them. Oranges are packed before being quite ripe; they ripen, however, upon the voyage, though at the same time the skin toughens, and they lose much of the tempting lusciousness of newly-gathered fruit. During the flowering season much blossom is collected by nuns and others for the purpose of making into sweetmeats.

To convey an idea of the importance and extent of the trade in these eastern provinces, it will suffice to mention that there is grown in the immediate neighbourhood of Blanca (province of Murcia) an average of 25,000 boxes a year.

Next in interest to the Orange plantations are the Rice fields. The cultivation of Rice is entirely dependant upon the valuable system of irrigation. All along the lines of canal there are well laid out and carefully prepared allotments of land, which are first levelled and then banked up with puddled clay walls, over which the water is allowed to flow to a depth of a few inches. In these flooded fields we see teams of horses (not oxen) ploughing the saturated earth, the seed being scattered broadcast by labourers who toil ankle deep in water. Some crops are already growing, and the pretty bright green shoots of the Rice plants are so thick as to nearly hide from view the water which still covers the roots. The valuable results of irrigation works in Spain are sometimes wonderful. Spaniards owe the adaptation of this valuable principle to those long-departed shrewd men of intellect, the ancient race of Moors. Indeed, the very works in Valencia which irrigate over 50,000 acres of land were constructed by them more than a thousand years ago. Kings of Spain, in subsequent times, have extended the system through other parts of the kingdom, but it is marvellous that the Spaniards have not had sufficient energy to carry it throughout the whole country. There are thousands, indeed millions, of acres of land which might be watered in this manner in the valley of the Douro, the Tagus, the Guadiana, and the Guadalquivir. English enterprise is doing something in this way for Spain; extensive works are in progress by an English company for irrigating 60,000 acres of land; and doubtless, if Spain would create confidence and assure protection for capital, any amount of English money might be found to increase such useful works. Land in Spain thus irrigated increases twelve times in value. Farms in the neighbourhood of Valencia are worth from £200 to £100 sterling per acre, and some in the adjoining province of Murcia even £500 per acre. These rich lands will grow corn, Rice, Olives, Vines, Oranges, Citrons, Pears, Pepper, Prickly Pears, and numberless other fruits, and the genial climate ripens two, three, and even four crops in a year. The value of water is of course very great, and many curious and interesting matters are worth noticing in connection therewith. In Lorca the water is sold every day by auction, and the value of the stream of water which supply the district may be estimated from the fact that a stream of water discharging a cubic foot per minute is worth an annual value of upwards of £2000. (*Ston's Tour through Spain with Cook.*)

FUMIGATING WITH LITTLE TROUBLE.—The following is for a house 20 feet by 12:—Take a sheet of blue paper and

soak it well in a strong solution of saltpetre; then thoroughly dry it, roll up in it 1 oz. of common tobacco, and place the roll on a flower-pot turned upside down. Set fire to it at one end, leave it to burn, of course shutting the house up first. Do not roll the paper up too tightly.—F. W. H.

NOTES AND GLEANINGS.

If there is one place more unlikely than any other in London where gardening would be pursued, it is in the dome of St. Paul's Cathedral, yet there, at an elevation of somewhere about 200 feet, we saw one of the officials tending his four small pots, the tenants of which were a Fuchsia, a Geranium, and two Musk plants. They were to him during his solitary door-keeping what the little weed which sprang up between the cell's pavement stones was to the prisoner—something to hope about and to benefit.

— THE thirtieth Anniversary Meeting of the GARDENERS' ROYAL BENEVOLENT INSTITUTION was held at the London Tavern, Bishopsgate Street, on the 2nd inst., Lord Henry Gordon Lennox, M.P., in the chair. Many leading horticulturists were present, including Mr. Alfred Snee, Mr. T. Moore, Mr. Marnock, Mr. J. Lee, Mr. B. S. Williams, Mr. J. Cutbush, and Mr. Andrew Henderson; and the eloquent appeal of the Chairman was responded to by subscriptions amounting to upwards of £400. As usual, the room was decorated with plants from the establishments of Messrs. Veitch, Williams, Lee, Rollisson, and others.

— THE *employés* of Messrs. James Carter & Co. played their annual game of CRICKET on the 29th of June. Those of the wholesale department were defeated by their brethren in the retail department.

— A HORTICULTURAL exhibition in aid of the funds of the WALSALL COTTAGE HOSPITAL—intended to be the first of a series of annual fêtes for the same laudable object—will, by the kind permission of Mr. W. H. Duignan, be held in the grounds of Rushall Hall, on the 6th and 7th of August. The prize list has just been issued, and is sufficiently comprehensive to give promise of a large and interesting display. The first division applies to cottagers only—that is to say, "persons not possessing a greenhouse, cultivating their own gardens, and not paying income-tax," to whom will be appropriated prizes for window plants; for cut flowers—namely, Dahlias, Roses, Asters, Marigolds, Hollyhocks (six blooms of each), and Pansies (twelve blooms); for collections of wild flowers made by children; for collections as well as single dishes of fruit; and for vegetables. The second division is for amateurs and professional gardeners; first prizes varying in amount from £1 to 5s., and second prizes varying from 10s. to 3s. 6d., being set down for stove, greenhouse, and bedding plants. In a third class for cut flowers prizes are respectively offered for twelve Roses (distinct), six Carnations, six Peonies, twelve Pansies, twelve Dahlias, six ditto, twelve Gladioli, Verbenas, six varieties (one truss each), twelve varieties of Hollyhocks, twelve China Asters, twelve French Marigolds, twelve African Marigolds, six varieties of Phlox, three ditto, six spikes of Stocks, vases or groups, bridal bouquets, hand bouquets, designs for table decoration, and collections of wild flowers made by children. There is likewise a fourth class for Pines, Melons, Grapes, Gooseberries, Raspberries, Currants, Cherries, Peaches, Nectarines, Apricots, Plums, Apples, Pears, Cucumbers, collections of fruit, collections of vegetables, and salads. The Honorary Secretaries are Mr. W. Bayliss, Wednesbury Road, Walsall, and the Rev. F. G. Littlecot, Rushall Vicarage, to whom applications for schedules or information should be forthwith made.

— THE eighteenth and last volume of "PRODROMUS," the great work on which three generations of the De Caudole family have been engaged for half a century, aided by the most eminent botanists all over the world, will shortly be published. Altogether the work will contain descriptions of about 59,000 species of plants, exclusive of Monocotyledons, to which it is not intended to extend it.

— PREPARATIONS are now being made for HEATING the whole of the forcing houses, &c., now in course of erection in the new gardens at Hatfield Park, Herts, the seat of the Marquis of Salisbury, on COWAN'S COMPENSATING SYSTEM, which consists in the combination of a lime-kiln and hot-water apparatus. A new kind of boiler is in course of manufacture expressly for the occasion. We believe Mr. Bennett had at one time decided to use either the Witley Court or Gold-

medal boiler, but wishing to give Mr. Cowan every possible chance of success, a boiler invented by the latter will be used.

— WE regret to have to record THE DEATH OF MR. J. A. GORDON, Superintendent of the grounds at the Crystal Palace, a post which he filled with great credit during the last twenty-one years. He had long been suffering from consumption, which terminated his life on Midsummer-day. He was in his forty-sixth year. Mr. H. OGLEE, for upwards of twenty years gardener to the Earl of Essex, at Cashiobury Park, also died on June 23rd, aged fifty-six.

— WE are glad to announce the publication, at the office of this Journal, of a THIRD EDITION OF MR. PEARSON'S "VINE CULTURE UNDER GLASS." This valuable little treatise has been revised by the author, who has made additions both to the letter-press and engravings. Among the latter we notice illustrations of several forms of vinery not figured in the previous edition.

TEACHERS OF CULTURE.—No. 2.

SIR ANTHONY FITZHERBERT.

UNTIL the time of Henry VII. (1485-1509) no power had the great proprietors to alienate or to divide their vast landed estates. At the Conquest the whole realm was carved out among the followers of the Norman invader, and the feudal system established. Each lord of the soil—so destitute of learning as to be unable to read, and without any occupation but the sports of the field by day and revelry by night—depended solely for subsistence upon the rents of corn, cattle, poultry, and other produce rendered by the serfs who cultivated the small parcels of ground permitted to be filled in each domain. Permitted to be filled, is not too strong a term, because the feudal manners of the time were all tending to foster and provide good hunting grounds for the lords of the soil. William I. strictly restrained within small limits the lands to be cultivated by a monastery he founded; and his son William Rufus laid waste cultivated lands to enlarge the hunting grounds where he met his death. These vast baronial domains descended inalienably to the heirs, and it was not until the time of Henry VII. that this fettering of landed property was loosened. Laws were then enacted enabling the nobles to alienate their lands, and these found ready purchasers among those wealthy men who then had accumulated and risen in influence—the mercantile classes. The birthtime was then of the country gentlemen, a class destined to improve and elevate our country with a rapidity not appreciable but by those conversant with the domestic history of the Middle Ages.

It was to aid the country gentlemen that Sir Anthony Fitzherbert wrote two books which entitle him to be placed as our first English teacher of land-culture. Neither the sons of the owners of the great baronial domains, nor the mercantile purchasers among whom the domains were parcelled, possessed the knowledge that was needed for their cultivation, and to impart that knowledge Sir Anthony wrote these books. How much they were needed is proved by eleven editions of the volume relative to cultivating the soil being published within fifty years after its first appearance.

That Sir Anthony's object was to impart this knowledge he tells in the "Prologue" to the volume, where, after referring to another volume previously published on the game of "the Chesse," in which the pawns he likens to "the yemmenne," he adds—"And in so moche the yemen in the sayde moralytyes and game of the chesse be set before to labour, defende, and maynteyne all the other hyer estates, the whiche yemen represent the common people as husbandes and labourers; therefore I purpose to speake fyrste of husbaudrye."

Sir Anthony also saw clearly that now lands were divisible into smaller and many parcels, it was needful that their owners should have due knowledge as to the preservation of their boundaries and rights, and for this he published his volume entitled "Surveyinge," because, as he observes, "It is necessary to be knowen, howe all these maners, lordeshypps, landes, and tenementes shulde be extended, surveyed, buttred, bounded, and valued in every parte: that the sayd estates shulde nat be decoyed, defrauded, nor dysherited of theyr possessions, rentes, customes, and services, the which they have to theym reserved, for mayntenance of theyr estates and degrees, and that there be no parcell thereof loste nor imbesolded."

How much such a work was needed or appreciated is proved by six editions being published between 1523 and 1567.

The orchard Sir Anthony assigns to the husbandman's care,

but the garden and Flax culture were the wife's portions of labour. Two brief extracts on these heads will suffice.

"It is necessarye, profytable, and also a pleasure, to a housbande, to haue Peares, Wardens, and Apples of dyuerse sortes. And also Cheryes, Filberdes, Bulleys, Dampsons, Plummes, Walnuttcs, and suche other. And therfore it is conuenyent, to lerne howe thou shalt graffe. Than it is to be knowen, what thynges thou must haue to graffe withall. Thou muste haue a graffynge sawe, the whiche wolde be very thynne, and thyeke tothed, and bycause it is thynne, it wyl cut the narrower kyrfe, and the cleaner for brusynge of the barke. And therfore it is sette in a compasse pece of yren, syxe inches of, to make it styffe

and bygge; thou muste haue also a graffynge knyfe, an incho brode, with a thyeke backe, to cleue the stocke with all. And also a mallet, to dryue the knyfe and thy wedge in to the tree; and a sharpe knyfe, to pare the stockes heed, and an other sharpe knyfe, to cutte the graffe cleane. And also thou muste haue two wedges of harde wood, or cyles of yren, a longe small one, for a small stocke, and a broder, for a bygger stocke, to open the stocke, when it is clouen and pared; and also good tough claye and mosse, and also bastes or pyllynge of wethy or elme, to bynde them with, &c."

"And in the begynnynge of Marche, or a lyttell afore, is tyme for a wyfe to make her garden, and to gette as many good sedes

SIR ANTHONY FITZHERBERT.

and herbes as she cunne, and specially suche as be good for the pottle, and to eate: and as ofte as nede shall requyre, it muste be weded, for els the wedes wyl ouergrowe the herbes. And also in Marche is tyme to sowe Flaxe and Hempe; for I haue harde olde houswyues saye, that better is Marche hurdes than Apryll Flaxe, the reason appereth: but howe it shulde be sowed, weded, pulled, repeyled, watred, washen, dryed, beaten, braked, tawed, hecheled, spon, wounden, wrapped, and wouen, it nedeth not for me to shewe, for they be wise ynough, and therof may they make shetes, bordclothes, towles, shertes, smockes, and suche other necessaryes, and therefore let thy distaffe be alwaye redye for a pastyme, that thou be not ydle."

The garden crops seem to have been scanty both in quantity and variety; and the same deficiency evidently characterised the gardens even of royalty, for in 1537 we find in the privy

purse expenses of Mary, afterwards Queen, that Apples, Cucumbers, "Strawberes," "Pescoddes," "Cherice," "Peyres," "Fylberdes," Wardens, "Scalet rotes" (Skerrets), "Hartichoks," "Medlers," and "Pepins," were brought to her as acceptable presents, the donors being often poor persons, but often friars, and the prior of the Charterhouse.

Fuller, in the century succeeding Fitzherbert's death, says that his publications are "monuments which will longer continue his memory than that flat blew stone in Norbury church under which he lieth interred;" and this prophecy is true, for the inscription is now illegible, although in Neve's time it was readable as follows:—"Of youre charitie prey for the soule of Sir Anthony Fitzherbert, one of the Kinges Justices of the Common Benche, and sometyne Lord and Patrone of this

towne, and Dorithie his wyfe, daughter of Sir Henry Willoughby, Kut., and dame Mawde his last wyfe, one of the daughters and heyres of Richard Coton of Hampstall Rydware esquier, by which he had five sonnes and five daughters, which Sir Anthony deceased the xvii. of May, an' Dni. 1538, and the said Mawde." That inscription did not even record, as is usual, the date of the deceased's birth, nor has there since been published any memoir worthy of him who was the author of some of the best of the early law books, who was the unflinching opponent of the despotic measures of Wolsey when at the zenith of his power, and, as we have noted, the earliest writer on tillage. It is not within our province to detail all the dates and events of his biography, but as we have searched for and gleaned them fully, we will record a few of the principal. Although the sixth son, he survived all his brothers and succeeded as the fourteenth lord to the manor of Norbury. He was appointed Justice of the Peace of Leicestershire, Lincolnshire, Staffordshire, and Warwickshire during the years 1509 and 1511, Serjeant in 1514, King's Serjeant in 1516, Justice of Assize on the northern circuit in 1518, and a Judge of the Common Pleas in 1522. He was one of the visitors of monasteries, but he opposed their sequestration, and on his deathbed exhorted his children not to accept or purchase any of the abbey lands.

The titles of his two works entitling him to our notice in these pages are, "A new tracte or treatyse moost pryfytale for all husbāde men;" and "The boke of surveyenge and improvemētes."

In the Exhibition of National Portraits was one of Sir Anthony Fitzherbert. It is the property of Sir William Fitzherbert, Bart., of Tissington Hall, Derbyshire, and from a photograph of that portrait our engraving is taken.

APHIS, OR GREEN FLY.

The various species of Aphidæ differ very considerably both in colour and form, but taking the Rose aphid as a type, we find it of flask-like form, somewhat resembling a minute animated soda-water bottle set upon long and slender legs. Its head is small, deformed beneath, and closely set upon the thorax. The proboscis, which is placed so far back as almost to appear to be attached to the thorax, is somewhat indented, and is composed of the mandibles and maxillæ, which are very slender and elongated, inclosed in the labium, which is formed into a canal of four joints, the last of which is well adapted to piercing vegetable tissues. The labium is long and pointed. The antennæ are long, composed of six joints: the two basal stout and oblong (the first stoutest, the second short and stout), the third longest with irregular warty projections. The remaining joints are shorter than the third, and do not differ materially from each other in length; the last is slightly forked near the base. The eyes are entire, prominent, and semi-globose, consisting of about two hundred and fifty facets, and containing a dark red pigment. The simple eyes (when they exist) are three in number, and form a large obtuse triangle; but in many species I think the simple eyes are absent, especially in the wingless members of the species, whilst in winged females, if not absent, they are often very rudimentary. The thorax is oval, with the prothorax forming a transverse collar. The abdomen is "elongate-conic," and on the fifth segment is furnished with an elongated tubercle or pap on either side; these tubercles are somewhat sealy towards the termination, the end is trumpet-shaped, and from them there at times exudes a clear, alkaline, saccharine fluid. Situated by the anus I believe there is an organ which I should be inclined to look upon as a pygidium; in some species, however, this is more marked than in others. The legs, six in number, are long, especially the hindmost pair; the tarsi are two-jointed, the first joint being shorter than the second, at the end of which are two hooked claws. By far the greater number of aphidæ are wingless. The winged members are usually (though irregularly) more marked with black, especially on the thorax and abdomen; the thorax is larger, and projects more above the abdomen, which is usually smaller, even in the winged females. The wings are four in number, the anterior pair much larger than the posterior; when at rest they are placed nearly perpendicularly on the sides of the body. The anterior have a strong subcostal nerve terminating near the apex in a broad stigma, and giving off three oblique nerves, the last of which is forked twice: on the posterior edge is a membrane, to which, when in use, three minute hooklets, situated near the apex of the posterior wing, attach them-

selves. The posterior wings are small, with two oblique nerves and the hooklets just mentioned.

Much has, I believe, been said and written upon the reproduction of these insects; but, as far as I am aware, all authorities are agreed that in the spring, the warming sun, and atmosphere generally, act upon the minute red or black eggs laid by the insects on twigs and branches in the previous autumn. In due course the eggs are hatched, and the young aphid emerges wingless: after changing its skin some three or perhaps four times, it commences, without interposition of a male, to give birth to living wingless young, who in their turn become mothers, and so the lineage descends to the tenth generation. I believe some difference of opinion prevails as to the number of generations that may transpire before a winged member appears. I am inclined to look upon the number as irregular, but have given the number which I have bred myself, which I think corresponds with Bonnet's observations. The tenth lineal descendant, at its birth, appears similar to its predecessors, but at the last change but one of its skin it possesses rudimentary wings, whilst on the final change taking place, the wings become fully developed. The general impression appears to be that the winged insects are the perfect male and female, appearing only in the autumn, and that the winged females produce eggs only, and that after having intercourse with a male. I believe this is correct so far, that winged insects are usually more numerous in the autumn, and at that period many of the females are unproductive until they have intercourse with a male, after which they lay eggs. But winged females do exist throughout the summer, though possibly less numerous than in the autumn, and they do not lay eggs, but produce living young without the interposition of a male; moreover, they produce young during the larval and pupal stages, the young never becoming winged, but living and multiplying in the manner usual with aphides. I have known eggs to hatch the same autumn that they were laid, in consequence, I believe, of warm weather setting in after some weeks of cold. As aphides die off in cold weather, I regard the laying of eggs simply as a means of preserving the species for the following year; the times when these eggs are laid I consider to be dependent upon temperature and atmospheric changes. The multiplication of these insects must naturally be very large, although different statements are made as regards the average rate at which young are produced; one authority says it is about three per diem, whilst another authority states the average rate of production to be fourteen per diem. Schrank, starting from Bonnet's observations, calculates the progeny of a single aphid during one summer at 23,740,000; whilst Réaumur says the offspring of a single aphid will amount to 5,904,900,000. I will offer no comment on these large figures, but as regards the daily average I may say I have never observed any aphid that produced young every day, those I have watched having brought forth litters, if I may be allowed the expression, at intervals of from three to five days, the litter consisting of from eight to fourteen individuals; and I believe the periods of production and number of young, are considerably influenced by temperature, &c. In wingless females I have frequently counted from thirty to fifty young in various stages of development, whilst twenty to thirty appears to be about the limits of young in the winged individuals.

Aphides are generally looked upon as being exceedingly stupid, and devoid of maternal feeling. Although general appearances are against their possessing much attachment for their young, I have seen instances where their actions would seem to show at least some care for their offspring. When the sap fails in any particular branch or leaf upon which a family has been feeding, I have seen the parent emigrating with her family on her back and clinging to her antennæ. I was rather curious to see if this was at the will of the parent, the caprice of the children, or by mutual consent; and to this end I took a mother, who was walking along with four of her children on her back, and placed them separately on a glass slip on the stage of my microscope, parent and offspring being close together. The mother immediately extended one of her front legs, so as to form an inclined plane, by means of which the little ones mounted, three to her back, and one climbed on to her antennæ. With a fine camel's-hair brush I then removed two of the young from their resting-place. The mother, apparently as soon as she became aware of the loss she had sustained, commenced walking in a serpentine manner across the slip, with her antennæ close to the surface of the glass; she shortly found her lost little ones, when the same process of as-

ending to a place of safety was gone through: the parent then set off in a straight line, waving her antennæ in the air with the peculiar motion common to aphides, seeking some locality more congenial to aphidian taste.

Wherever there is vegetation—roots, branches, leaves, flowers, or fruit, it is more than probable that aphides will occur, although I have no doubt exceptions to the devastations of this tiny plague of the field and garden may be found. Amongst the most destructive of these insects may be mentioned the Hop and Potato fly, both of them akin to our type, the Rose aphid. There would appear to be as much variety in the insects as in their habitat—long and short antennæ; long and short legs; winged and wingless; long tubercles, short tubercles, and no tubercles; these features will be found subject to innumerable modifications as well as form, size, and colour of head, proboscis, eyes, and body. A very peculiar form of insect from the Walnut tree is remarkable for the hairs on the head and legs; its appearance would almost induce one to suppose it to be a form intermediate between that of the Rose aphid and the well-known leaf insect; but the peculiar life-history of the latter would cause it to be reckoned as an abortion rather than a natural form of aphid. A very peculiar form of hind-leg will be found on several varieties of aphide living at the roots of plants. The tibia is as short as, or in some cases shorter than, that of the front legs, the first joint of the tarsus is short, but the second is exceedingly long, almost as long as the tibia. The hind leg of an aphid taken from the root of the Endive shows this peculiarity. The too-well-known American blight belongs to a class of aphide, distinguished by their wool-bearing bodies, and the absence of tubercles. This class is generally said to be wingless in all its stages, and dependant upon the wind for transportation to new homes. I have, however, captured a woolly aphid with wings, but cannot name its habitat, as I took it on the wing.

I can find no difference in appearance between insects taken from widely different trees; for example, one taken from the Oak was found to correspond with another taken on the Larch. Hence, speaking of insects as oak-aphid, &c., leaves one in a certain amount of doubt as to the individual insect spoken of, and in consequence of the classification being in so crude a condition it is very difficult to enumerate the number of species and varieties. I have, however, found aphide presenting more or less distinctive features on the Apple, Milfoil, Oats, Wych Elm, Walnut, Sow-thistle, Lime, Calceolaria, Larch, Plum, Maple, Thistle, Barberry, Scotch Pine, Potato, Oak, Spindle tree, Sycamore, Juniper, Dock, Goranium, Honeysuckle, Canary Grass, Rose, Willow, Fir, Sow-thistle root, Hop, Mallow, Privet, Parsnip root, Pea, Birch, Endive root, Cabbage, Wheat, Poppy, and Grass root, and I believe 326 species are catalogued and described at the British Museum.

The affection and care shown for aphide by ants are well known; where the "green fly" is numerous, bodies of ants may often be seen carrying them away to the captors' underground dwellings, the ants holding their prisoners by the skin of the upper part of the thorax or abdomen; some assert that it is only one species of aphid that is thus cared for by the ant, but this I am inclined to doubt. I rather think it depends very much upon the locality of the ant's nest, and what tree or plant-roots run through the habitation. This one staunch friend is however amply compensated for by innumerable enemies; a group of aphide is a dainty dish for most small birds, who search them out and nibble them up with evident gusto. Many of the Ichneumon flies seek the aphid to lay their eggs in. The stricken aphid usually separates itself from the herd, and as the larva of the fly grows, it swells and becomes gouty in appearance; ultimately it dies, as the fly is ready to leave its host, which has then become a distorted horny shell. Many people mistake the cast skin of the aphid for the corpses of those attacked by the fly; it seems odd that such mistakes should be made, as the one seems to me no more like the other, than a dead Daniel Lambert would resemble a suit of cast-off clothes. Ladybirds, both in the larval and perfect state, feed largely upon Aphide, but perhaps the worst insect enemy they have is the larva of the Lacewing fly: this is a near relation to the Ant-Lion, bearing some relation to it about the jaws, which gives it a hungry, cruel, and malignant look, although its appearance in no way belies its character. I believe the aphid has another and most deadly foe in disease. I was astonished at the rapidity with which a brood I had died-off, so I carefully watched one of them to try

and discover the cause. I found (that usually after changing a skin) the aphid was more pearly-coloured than usual, then changed to the colour of pale ultramarine ash, and then to a dirty reddish yellow; the opaque green layer or middle skin of the insect appeared to be absorbed, and the blood could be seen circulating in the interior of the insect. Red-coloured globules then appeared in the fluid, after which a slight down covered the outside of the skin, and the aphid shortly tucked its legs under it and died. I will not pretend to say positively that the disease was caused by a parasitic fungus, but I am strongly inclined to think such was the case.

After all, perhaps the most inveterate enemy of the aphid is the gardener; he fumigates, powders, syringes, dips, and brushes his plants, but still does not entirely rid himself of his pests; although when the area is limited he meets with partial success; still in the Hop garden and Potato field but little can be done to check these rapidly multiplying destroyers of the cultivator's profits. Where the result is most disastrous, the less appears capable of being done to check the ravages of this tiny destroyer. Fumigation, from its very nature, cannot be put into practice, and other methods of destruction may be considered as of little use where large quantities of plants are close together; the probability then is that the best mode of securing ourselves against the damaging attacks of the aphid is to encourage the preservation and multiplication of insects that prey upon them, such as the Ladybird and Lacewing fly.—(*English Mechanic and World of Science. Extracts from a Lecture by Mr. E. P. Pett.*)

WORK FOR THE WEEK.

KITCHEN GARDEN.

The weather during the past week has in many parts of the country been particularly favourable for planting out the main autumn and winter crops. Where Broccolis are planted between Peas a narrow space should be dug for them if the ground is very hard; the rest of it can be dug and the intermediate rows of plants put in when the Peas are off. As the heads of *Artichokes* are taken the stems should be cut close to the roots; clear the stools from decayed leaves, and loosen the surface of the soil about them with the hoe. No time should now be lost in getting out those varieties of *Broccoli* which come in during the autumn; they may now take the place of the early Peas. Earth-up the *Cauliflowers* that were planted at the beginning of last month; plant more for use in the autumn. The main crops of *Celery* should now be planted out; loosen the earth about the early crop, and give it good supplies of water if there is not sufficient rain to keep the soil quite moist. Keep the linings of the *Cucumber* frames made up, so as to afford a gentle warmth through the bed, for however warm the weather may be, this is necessary to procure fine handsome fruit. As soon as the tops of *Garlic* and *Shallots* begin to die pull up the roots; after allowing them to remain on the ground a day or two to dry, tie them in bundles, and hang them in a root-cellar. Another sowing of *Lettuce* should be made in drills where the plants are to remain; a little of the Paris White and Bath Cos may be sown at the same time. Save and prepare horse droppings for *Mushroom* beds to produce through the autumn and winter; take care that the newly-made spawn bricks are thoroughly dry before being laid by. Sow a few rows of *Spinach* to keep up a succession, thin the preceding crop, and keep it watered in dry weather. Thin-out the last sowing of *Turnips* to a foot or 15 inches apart, and as the weather is now favourable, the main autumn crop may be sown.

FRUIT GARDEN.

Protect fruit from birds by covering the trees with nets. Where Currants and Gooseberries are required to be kept on the trees late in the season, they should be matted-up. Finally thin wall fruit. Keep the shoots of the trees neatly laid in. Do not uncover the fruit more than is necessary. Give espalier trees their summer pruning. Keep fruit borders frequently hoed and raked. Pinch out the point of the present year's wood of the Fig before nailing-in. Stop and nail-in Vines, and continue to carefully watch the progress of the green fly. When new Strawberry plantations are intended, prepare the ground by deep trenching and well manuring with rotten dung. Layer into 3-inch pots a sufficient number of the desired kinds of plants for the purpose. This little trouble will be amply repaid by the quantity and quality of the first year's crop.

FLOWER GARDEN.

The recently-planted beds will still require watching to get the plants in them fairly on the start. The heavy rains of the last month have chilled the ground, and some of the more tender or badly-rooted plants look sickly. As the grounds and shrubberies are much frequented by company at this season, pay

more attention in keeping the greatest neatness and order in every part where there are hands to admit of it. Flowering shrubs as they go out of bloom should have their dead flowers, &c., removed, and be slightly cut back. For the same reason remove the seed pods from Rhododendrons, tree Peonies, &c. These little attentions (where they can be given without infringing on more important matters) will be attended by an increased growth of the plant, and a greater certainty of their blooming every season. The propagation of Carnations, Picoetes, Cloves, &c., should not be longer delayed. As cuttings of the young grass will succeed at this season, a slight hotbed should be made, on which place a few inches of very sandy compost; Select the weakest grass for cuttings, and place an air-tight hand-glass over them. The strongest shoots left will answer for layering. The present is the favourable time for putting in cuttings of all the more showy herbaceous plants, selecting for the purpose the small shoots not furnished with bloom. A north border is a suitable place to strike quickly. Pansies for autumn blooming may be treated in the same way. Hedges should be well cut-in with the shears. As a deciduous plant for hedges, nothing is better than the Turkey or hybrid Lucombe Oak; and *Taxodium sempervirens* will be found a most eligible plant for making evergreen hedges, as it grows quickly, bears the knife well, and has an agreeable appearance. Push Dahlias on by watering freely when the weather is dry, also assist them by mulching the ground with decayed stable manure. Take care that the plants do not chafe where attached to the blooming-sticks.

GREENHOUSE AND CONSERVATORY.

During the time when house climbers are in an active state, make it a rule to go over them frequently, that they may not grow into a confused state. The same may be said of climbers in pots, which require attention for the same reason every few days. Any shoots which have done flowering should be cut back and a crowded growth avoided. A number of hardwooded plants which were cut back some weeks since will now have recovered themselves and be commencing a fresh growth. This is the proper time to shift into larger pots any plants requiring it. Carefully loosen the outside roots with a small pointed stick. After potting keep the plants closer for a few days and syringe them daily, but avoid giving any more water to the roots than is sufficient to preserve the old ball moist. To prevent watering so quickly after potting, mind the roots of the old plants are well moistened before being potted. The greenhouse plants out of doors will require the canvas or tarpaulin being drawn over them during heavy rains. Those still remaining in the house must have abundance of air. Watch narrowly for green fly, which often does considerable damage to such things as *Leschenaultias* before it is found. Fumigate or wash with weak tobacco water wherever there is the least indication of its appearance. Whenever room occurs in plant houses take a few of the most forward *Fuchsias*, Japan Lilies, and *Gladioli* to assist in keeping-up the floral display. *Brugmansias* and other vigorous-growing plants should be frequently assisted with manure water, as they are liable to be infested with insects. Use the syringe freely to keep them under before the plants come into bloom. Orange trees and many large specimen plants require less water about this time, but diminish the quantity very gradually. If the plants in the greenhouse are now all of the true greenhouse kinds, give them as much air as the house will admit; but if, as is generally the case at this time, they are a mixed collection of half stove plants and annuals, you must keep them close at night with a very damp atmosphere, and you may let the house get well heated by the sun before you give air in the morning. Training and staking plants, surfacing pots, and similar routine business, need not be recapitulated.

STOVE.

For the next six weeks or two months, according to the weather, stove plants ought to have more air and light than at any other period. After this time, therefore, shade as little as possible, with the exception of Orchids or young and newly-propagated plants. Seeds of those splendid *Clerodendrons* which make such a fine display at summer exhibitions, should be sown as early this month as possible; they will flower at this time next year or earlier, and seedling plants are much easier to manage than those from cuttings. So far as Orchids are concerned, those showing indications of matured growth may be first removed to the cool end of the house for a few weeks, and afterwards placed in quarters where the temperature and atmospheric moisture will not interfere with the slow progress of the plant towards a state of rest. *Dendrobiums* and others of that class should be grown on till the shoots are of sufficient length. Wash any plants infested with insects with a lather of common brown soap, using a sponge for the purpose.

PITS AND FRAMES.

When rooted cuttings are potted-off they should be removed to a frame by themselves, where they must be shaded until they make fresh roots. Bud Lemon and Orange stocks if the bark runs freely. Put in cuttings of *Chrysanthemums* to pro-

duce dwarf plants. Repot rooted plants as they require it.—
W. KEANE.

DOINGS OF THE LAST WEEK.

SINCE writing last week's doings we have had two refreshing showers; in all 0.88 inch of rain fell. We had just determined to begin watering in earnest, as bedding plants and florists' flowers, as well as Peas in the kitchen garden, were showing evident signs of distress—indeed, not only in the gardens, but in the fields was the want beginning to be felt. Potatoes and other green crops are now making giant strides towards full development. Some of us were grumbling very much at the backwardness of the season; we ought now to be ashamed of ourselves, and be truly thankful for the present propitious weather.

KITCHEN GARDEN.

Although we have been incessantly working amongst all crops, and running the hoe through all the borders, we noticed that some weeds had been left, and where they showed signs of running to seed a man with a basket soon cleared a large space by pulling them out with his hands. We also seized the opportunity, when the walks were wet, to pick out the weeds. It is of little use weeding walks when they are dry and hard; it takes much longer to get over them, and not only so, but many weeds are broken over, and will grow again as soon as rain comes. We also planted out *Brussels Sprouts*, *Savoys*, hardy *Greens*, *Celery*, &c.

The *Asparagus* beds having become full of young seedling *Asparagus* plants, we had them forked out before the beds were too thickly covered with the "grass" of the old plants; the hoe run over afterwards made them right for this season. Much of the early-planted-out *Celery* has run to seed; in some instances whole rows had to be pulled out and replaced with later-sown plants.

FRUIT AND FORCING HOUSES.

Pines.—We have been removing some of the largest plants and those showing fruit from a succession house into the fruiting house, to replace those which have ripened-off their fruit. Where there are only small houses and few of them, the best way to obtain a succession of fruit is to remove a few plants into the fruiting house, keeping those which are throwing up fruit and ripening it off at one end of the house, and placing those that have yet to throw up fruit at the other end, where they can have slightly different treatment afforded to them. Admit air freely into the house where the fruiting plants are.

In the early *vineries* we have had nothing to do but to pinch-out all the young growths as soon as they are formed, and to keep the leaves free from red spider. In the late houses the same attention has been given to stopping the lateral growths. We are particular to stop the growths as soon as they are formed—that is, if the roof of the house is well furnished with leaves; if this is not the case the laterals are trained to the wires to fill up any vacancy. Other Grape-growers have different methods. On one occasion we saw strong canes under and over the hot-water pipes, running over the surface of the ground in all directions, as well as coming down the back wall, while the roof of the house was densely covered with foliage. This treatment was to cause the formation of roots, which no doubt it did, as the more foliage and growth allowed the greater will be the increase in the root-action; but we only mention the system to express our disapproval of it. In the second house we must mention two sorts of Grapes that are good this year—viz., *Golden Champion* and *Royal Ascot*. The first-named has been finer than we ever had it, but, notwithstanding this, it has proved to be so uncertain that we cannot recommend it. *Royal Ascot* has been particularly fine in bloom and size of berry, but it is not so fine in flavour as most of the others, and has the fault of being attacked by red spider sooner than most of the old sorts.

Cucumbers and Melons.—Melons have been generally good this year, although the season has been rather unfavourable for them; this is accounted for by the fact that the system of growing them trained to wires is more generally adopted than it used to be. The old system of planting on a mound of earth over a dung bed in narrow lean-to pits, and the plants trained over the surface, is not good and ought to be done away with. Our first house is done, and the second nearly so; and as they are required for other purposes, we shall not plant again, otherwise had the plants been ready in good-sized pots another crop could have been easily obtained in August. There is one thing should be noticed here, and that is the rapidity with which any insect pest spreads on Melon plants. We have noticed a house of healthy plants, which were apparently free from red spider, in about ten days entirely ruined by this pest. We had a new experience in this during the present season, by having one house attacked by green fly; this of course can easily be destroyed by fumigation. Red spider must be syringed off before it spreads too much. The Cucumbers may be said to be the same thing from week to week, as one house continues to supply us with

fruit from the same plants all the year round; about a dozen fruit are sometimes cut at one time, and laid up in the fruit room, which gives us an opportunity to thin-out the shoots more freely, and to cut off any old leaves that may become infested with thrips or spider. Thrips are very destructive in Cucurbit houses, and are not easily destroyed; fumigating the house two or three times in succession with tobacco smoke will keep them under, but it is best to continue fumigation until they are quite destroyed.

CONSERVATORY AND PLANT STOVE.

There is continuous work here in the way of re-arranging plants, as the flowers are not so lasting as they are in cool weather; but we do not care so much for flowers here, when the flower garden and borders are at their best. We have been re-potting Chinese Primulas, Tree Carnations, and other plants of this nature, to furnish us with flowers when there are none to be had out of doors.

Chrysanthemums also claim attention in the way of sticking and tying-out the shoots of specimen plants. The young shoots had become infested with aphides, which would soon have checked their growth; they were dipped in tobacco water, which effectually destroyed the aphides. Some dry snuff shaken over them would have answered the same purpose, and can be more readily applied. We have also very nearly finished potting all of them in their blooming pots. Those intended for cut flowers were placed three plants in 11 or 13-inch pots, and a few pairs of plants in 9 and 10 inch pots. The specimen plants were potted in various sized pots from 8 inches up to 15 inches inside diameter. The pots are always crocked with oyster-shells, and the same material pounded-down serves to mix with the compost in which the plants are potted.

FLOWER GARDEN.

The beds are now at their best, and much care is taken to pick off all decaying flowers as soon as they appear to fade. The Rose beds and borders must be looked over every third day, as decaying Roses on standard or dwarf plants cannot be permitted. They are free from green fly this year, and the worm which attacks the bud as soon as it is formed has not been so troublesome to us as it is sometimes. Our soil is not adapted for herbaceous plants, as a large proportion of them require a soil of good depth and of some holding power. In our shallow gravelly borders they require much attention, especially as regards watering; if neglected in this particular many of the more delicate die altogether. In all gardens where things are expected to be done in first-rate style, and where labour is highly paid, it is best to have the water laid-on to all parts of the garden, so that hose can be attached and the water spread over the ground easily and quickly.—J. DOUGLAS.

TO CORRESPONDENTS.

•• We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

BOOK (*Fidget*).—Our "Flower Garden Manual" contains the treatment of Pelargoniums, Fuchsias, &c. It may be had free by post from our office for five postage stamps.

FRUIT (*H. P.*).—Write to Messrs. Webber, Central Avenue, Covent Garden Market.

DEAD CEDAR (*G. R. B.*).—The leaves being white at the end of each shoot, it is only a sport, occasioned, probably, by the roots having descended into an unfavourable soil.

VEITCH PRIZES.—Mr. Wakefield, who took the first prize for Black Grapes on the 3rd inst (see page 31), is gardener to F. Gretton, Esq., Bladen House, Burton-on-Trent, not Leamington, whence, however, he sent his entry.

HEATING A SMALL GREENHOUSE (*J. Wilson*).—Any pan-stove with a 9-inch ring of flues, and a tube to carry the fumes into the open air, would be sufficient to exclude frost from a house 12 feet by 9 feet.

STRAWBERRIES (*A. B. G.*).—Even if in perfect order we cannot name Strawberries, they are too slightly differing; but your two berries were reduced to a pulp, and the box streaming with their juice.

ROSES WITH GREEN CENTRES (*M. E. W.*).—Early pruning and cold weather in spring, which give a check to the sap, are often the causes of green eyes in the centre of Roses. There is, we fear, no royal road to prevent it. It is never wise to have early-pushed buds on the plants at pruning time, which may do for the sake of having earlier blooms.

SEEDLING GERANIUM (*M. V. W.*).—It is not equal to many of similar colour and leaf.

SPIDERA JAPONICA AFTER FLOWERING (*Lady Subscriber*).—The plants should be kept in a cold frame if they are out of flower before May, and ought to be kept there with abundance of air and due supplies of water until the middle of that month, or later if frosty. They should then be plunged outdoors, and must be well supplied with water throughout the summer. If the spot is sheltered they may remain until wanted for forcing, and may then be shifted into a larger-sized pot. Ours under this treatment increase in size annually, and as a rule produce double the number of spikes of bloom. They are in large pots—masses giving fifty or more spikes of bloom.

IMPROVING SOIL (*Idem*).—The soil you sent us is very barren, being mostly sand. The insect in it—for we only found one—is the wireworm. To destroy it we would dress the uncropped ground with gas lime at the rate of twenty bushels per acre, and point it in with a fork. To improve the land we should add all the turfy loam we could, and at the same time apply a good dressing of stable or farmyard manure, not more reduced than will permit of its being dug-in. The addition of fresh soil we should most rely on, applying as much of that as you could procure, also of dung. With these applications this autumn, dig-in and throw up roughly for the winter, forking over in frosty weather in February, a good lining in March (100 bushels per acre), and fork-in, we think you may next year put in the various kinds of kitchen-garden crops, as well as flowers, with every prospect of success.

PEAS DISEASED (*A. F. S.*).—The Peas, from your description, are suffering, and have died, from the coldness of the soil and long-continued cold weather. Though ours have not died they have suffered to a considerable extent, having turned yellow, but only those of the Wrinkled Marrow section. The best means of saving the crop in future would be to dress with quicklime in spring, and point it in before sowing. When the Peas appear above ground dust them and the soil with quicklime every week or ten days until earthed. You will not find them die-off next year.

TREATMENT OF TRICOLOR AND BICOLOR PELARGONIUMS (*Fidget*).—The plants are best shielded from powerful sun, hot sun being fatal to good colouring. We would have an awning of tiffany on a roller to let up and down by a cord and pulley, using it only during bright sun. The soil we advise for the Tricolors is fibrous loam, neither heavy nor light, three parts, leaf soil one part, half a part old cow dung, and half a part silver sand and pieces of charcoal in equal proportions, the whole well mixed. Be careful to afford good drainage, and do not overwater, especially soon after potting, and yet they should never be allowed to become thoroughly dry. This applies more particularly to Bicolors. They should be kept near the glass and have abundance of air. We do not advise mixing peat with the soil for these Pelargoniums. The plants from cuttings of last year should soon have a rest by being kept dry, and should then be cut down like other Pelargoniums.

GRAPE BUNCH SHRIVELLED (*Idem*).—The bunch you sent us is shrivelled in consequence of the Vine roots being in soil of a much lower temperature than that in which the leaves are growing; hence the sap is not furnished rapidly enough to meet the requirements of the foliage. The only remedy is to keep the temperature of the house rather low by a free admission of air in hot days in the early stages, or until the Vines are coming into flower, or to apply heat to the border.

CUCUMBER LEAVES SPOTTED (*G. W.*).—We think the leaves have been scorched by the sun, but the spotting may have been caused by the fumigation. They exhibit no indications of insects. We should give a little air early in the day, so as to have the leaves dry when the sun strikes powerfully on them, and in fumigating be careful to deliver the smoke cool and not too strong. Put flowers of sulphur on the hot-water pipes.

IVY CUTTINGS (*F. J.*).—You may put in cuttings of the young shoots of the current year as soon as they become firm, which they will be about this time. It is not necessary to have a portion of old wood, but they may be cut into pieces of 6 inches, and inserted two-thirds their length in light sandy soil in a shady border, keeping moist. We prefer the short stubby shoots 6 or 8 inches long.

MORELLO CHERRIES FALLING (*Idem*).—It is very common this year, which we attribute to the long-continued cold, and this has not conducted to the thorough setting of the fruit, or it may be a result of the wood being imperfectly ripened last year, owing to the cold and wet of the late summer and autumn. With us all kinds of out-door fruits, except Apples, have set very liberally. The pinching of all shoots which you cannot lay-in is right. It would not cause the fruit to fall.

THINNING PEARS (*Idem*).—We should thin-out the fruit in each cluster to two or at the most three, not leaving more than two or three dozen on each tree. The fruit will be finer, and the trees will not be injured by the crop named if you feed them well at the roots.

GALLS ON MALE BLOSSOMS OF OAK (*C. J. G.*).—The galls sent appear to be shrivelled-up Currant galls, as they are formed, caused by the punctures of *Cynips quercus-pedunculata*. The gall dies will appear next spring. Male gall flies are well known.—I. O. W.

GALLS ON ELM LEAVES (*J. E. Skinfold*).—The very numerous excrescences on the Elm leaves are galls formed by a plant-louse, *Aphis gallarum ulmi*, each gall being inhabited by a small brood of the young of these insects.—I. O. W.

STRAWBERRIES FOR SUCCESSION (*A. C. H.*).—Viscountess Héricart de Thury, President, Sir Joseph Paxton, Dr. Hogg, and Frogmore Late Pine. There are no late varieties of Asparagus.

AZALEA and CAMELLIA CULTURE (*A Very Old Subscriber*).—When the growth is made and the buds set, place the plants out of doors on ashes, in a position shaded from the midday sun, taking care that they do not suffer from want of water. The hot and dry conservatory would be altogether unsuitable, also the vinery after the growth is made.

CINERARIAS and CALCOLARIAS (*Idem*).—The plants would thrive much better if placed on ashes on a shady border sheltered from winds, and should be kept moist. A hot and dry conservatory is not suited to them.

TRANSPLANTING VIOLETS (*Idem*).—You may now take off the rooted runners or suckers and make a new plantation, shading them from bright sun, and watering in dry weather. It would have been better to have planted them earlier.

HOSE CHENTNUT AND SYCAMORE LEAVES DRIED-UP (*J. B.*).—Not knowing more than the fact that the leaves are dead, we can only say, that as there are no fungi upon the specimens sent, we surmise that the roots have descended into an obnoxious soil.

GRAPE SPOTTED (*An Orphan Gardener*).—Remove all the spotted berries and water the roots of the Vines copiously with tepid water once a fortnight, and the alternate week with very weak liquid manure.

DISTINGUISHING CARNATIONS, PIOTEEES, AND PINKS (J. W.).—Carnation marks are in flakes or ribbons of colour from centre to edge, and through the edge; and the more dense these ribbons, or stripes, or flakes of colour are, and the more distinct the white ground between them, the better, and the more equally divided as to quantity they are the better. As the petals are broader as they approach the outer edge, so also are, or should be, both the colour and the white. They are divided into classes called Bizarras and Flakes, the former having two colours of stripe besides the white, the latter only one colour. These Bizarras and Flakes are subdivided, there being purple flakes, rose flakes, and scarlet flakes; and among the Bizarras, scarlet bizarras, which have scarlet stripes, and a second colour, which is considered better for a rich contrast of black, and approaches to it; then purple bizarras, which have purple stripes, with a light pink or rose, or some other colour, forming a contrast. The Piotee has the colour only on the edge, and broad or narrow, as the case may be, but ramifying towards the centre; any mark or spurt of colour that does not touch the edge is a blemish. Some, therefore, are only marked round the edge very distinctly, but as narrow as possible; others have a sort of feathering, narrow or deep as the case may be, but feathering inwards from the edge; the outer edge solid, and the inner edge rough or feathery. The Pink is distinct from both these. The lacing, as it were, of a Pink is rough outside and inside, with a portion of white outside the lacing, as if a band of colour had been laid on; besides this, there is colour at the base of every petal, and, perhaps, one-third of the distance along the petal, so that it forms an eye or centre of colour, which is peculiar to itself, and which never occurs in the Carnation or Piotee. A Pink without its lacing all round each petal, and its narrow strip of white outside it, would be worthless as a show flower. The more distinct this lacing is the better; it should look like an even piece of embroidery, just fairly within the outer edge of the white.

GRUB ON PEAR LEAVES (J. C. A.).—It is the slimy grub, of which we gave drawings and full notes in our No. 638, published June 19th. Dust slaked lime over the grubs.

NAMES OF ROSES (H. C.).—The petals were all falling off when we received them; we believe No. 1 is Charles Lefebvre; 20, General Jacquemont; 32, Lord Raglan. It is very difficult to name florists' flowers from single specimens in a flagging state. We are nearly sure of 29 and 32, but No. 1 might be Madame Victor Verdier.

NAME OF FRUIT (C. Smith).—Barcelona Pearmain.

NAMES OF PLANTS (Inquirer).—1 and 6, *Lactuca dilatata* (?); 2, *L. Filix-mas*; 3, *L. Filix-femina*; 4, *Polystichum angulare*; 5, *P. aculeatum* (?). (*F. H.*)—1, *Oxalis incarnata*, a Cape species, and, therefore, certainly not the Shamrock, though what plant was originally so called is open to question. 2, *Eutoca viscosa*, a Californian annual. (*John S.*)—A species of *Cotoneaster*. (*M. M.*)—*Kalmia augustifolia*. (*Young Gardener*).—2, *Sclaginella uncinata*; 1, *S. apus*; 1 and 3, indeterminate without fruit. (*R. H. C.*)—1, *Hypolepis repens*; 2, *Pteris scaberula*; 3, *Cystopteris fragilis*; 4 and 5, *Pellaea hastata*. (*A Subscriber*).—We cannot name florists' varieties, nor plants from leaves only.

POULTRY, BEE, AND PIGEON CHRONICLE.

POULTRY PAST AND PRESENT—THE LAW OF DEVELOPMENT.—No. 3.

In my last paper on this subject I tried to show by the example of the Game fowl, that if the attention of the breeders of a variety be mainly fixed upon one point, or set of points, other points will and must lose, while those sought increase in perfection. It will be found on examination that this law is general, and explains most of those changes of fashion which can be remarked in poultry-breeding. But it will also be found on examination that when perfection, or what is considered sufficient perfection, is once reached, other points can be attended to without much depreciation of the points already gained, provided only these last are not, as often happens, again comparatively lost sight of.

I have been singularly interested to observe how this simple law is to be clearly traced through the past history of many breeds, as shown by the copious notes which have been placed at my disposal by various breeders for the work on which I am now engaged. A good example is found in the Spangled Hamburgs. Mr. Beldon—than whom there can hardly be a better authority—believes that the original of this breed was the Yorkshire Pheasant, from which, by careful breeding, was made the Lancashire Mooney. In this breed, as is well known, the spangling of the hens was the one point sought, and it was obtained in glorious perfection. But in fastening attention upon this other points were lost sight of, and accordingly the breed deteriorated in neatness of head, in ear-lobe, and in the plumage of the cock, which, there can be little doubt, became hen-feathered through this close breeding to get well-spangled hens, as it is still found that heavily-spangled cocks are the best for this purpose. After awhile the neglected points were required by the judges, but were only obtained at first by such a sacrifice of spangling in the hens that these could not be shown, the Mooney being required to be shown in this sex. By degrees, however, the pullets produced by the cross became better and better, till at length several Hamburg breeders possess strains which breed first-rate Silver-spangled cocks, while yet the pullets produced are little inferior to the old Silver Mooneys, which have consequently almost disappeared. Other instances could be named, but one adequate illustration is as good as many, and I am anxious to come to the practical application of what we have been considering.

If I wished to put that into the fewest words, it would be those

of the old proverb, "One thing at a time," a maxim which deserves writing in letters of gold, so little is it understood by young and inexperienced fanciers. As a rule they will not believe in it till they have tried the other way and lost heavily by it; and many never learn it at all. But I never knew a good breeder of any breed who did not act upon it, whether he thought he did or not. The young amateur, however, goes on a different plan. Having mated his birds and bred his first-year's chickens, he finds he has in his yard, in all probability, some prevalent fault. He buys a cockerel at a good price to remedy this fault, and breeds again. Probably this fault is somewhat better, but some other fault now appears, and he now perhaps buys another bird, or, if not, mates up his own, almost entirely with a view to remedy that, when he finds to his dismay that either the first fault, or perhaps a third, again appears to trouble him, and show that he is as far off perfection as ever; and so he goes on. It has been the experience of hundreds.

Now the reason of all this is, that he has never bred for any point of perfection long enough to really fix it in his yard. He never stays to secure what ground he has already gained, but throws this away while trying to get some more. He has no fixed ideas, which all good breeders have, and he gets the proverbial reward of every man who works without a purpose or a plan. He tries to remedy fault after fault, just as it appears the most glaring of the season to his eyes, and if there be any brief change of fashion in judging, as there occasionally is (generally, I believe, it will be found, these changes of fashion occur in order to counteract the faults of the day), he tries to meet them too. In brief, he fails simply because he does not understand it must be one thing at a time.

Every breed has its ideal standard or model. The amateur must first get this well into his mind; or, if he thinks the understood ideal faulty, he is at liberty to form in his mind a better—if he can. Few men think exactly alike on these things, and hence the differences we see in different strains. Now, having formed his ideal, he has to consider what class of points are at once the hardest to secure, and the most valuable when made permanent. In nearly all varieties these are beyond question the points of colour or feather. As a rule, therefore, these should be the first points bred for, and breeding should for several years be mainly directed to securing them in the highest perfection, and in such a degree that the stock can be depended upon to breed birds satisfactory in this respect. While doing this other points need not be altogether ignored, of course; but they should be kept somewhat subordinate, and only a general kind of attention be given to them to see that they do not become very bad, while the ground being more specially cultivated is made thoroughly secure. Then, when so much has been done, comparatively little care will be needed to preserve the points thus attained, and from the chickens bred from the strain thus far formed such may be selected as present other points desired. Crossing, or at least a thoroughly alien cross, should very rarely be ventured upon, nearly always doing much harm from a mere fancier's point of view, for the simple reason that you can never be sure the bird selected has been the product of a similar "course" of breeding to your own yard, and if not, he will introduce an element of uncertainty which is undesirable, and often dangerous. But by steadily persevering with one stock, working steadily towards a definite object, and securing all ground really gained, a gradual but sure approach to excellence will be ensured, and every year will see something evidently gained.

This, then, is what I mean by the law of development. You have simply to breed steadily towards any desired point, selecting those birds which show it best, and you infallibly get it (if the standard you set up be a possible one), if you keep on long enough. While doing this you can pay only subordinate attention to other points; but when done you can pay more to them also, since your fixed strain will give you so many birds with the points you first sought, that you can select from them all you want to secure the next point. It is simple as A B C, and bears the same relation to the whole science of breeding which those letters do to all written language. I am not sorry that the difference between some breeds of poultry past and present has given me occasion for a few words upon it.—L. WRIGHT.

EXHIBITING SINGLE BIRDS.

It is surprising that more has not been said on the single-bird system. However, the number of letters that may appear in print is not always an index of feeling on a subject. I do not exhibit much, but when I do exhibit I prefer those shows where the single-bird system is adopted. Small breeders like myself find it almost impossible to show where the above system is not adopted. A man might possess a good male bird and two good hens, and yet not be able to exhibit a pair. Two birds that did not match might possess greater merit than two that did, yet the latter would win. I bred from thirty to forty chickens (Buff Cochins) during the season, and I obtain two fit to exhibit anywhere, I am more than satisfied and yet how very impro-

bable that the two would match. Even the large breeder finds it difficult to match his birds. How must it be, then, with the majority, who are not large breeders? The small breeder has plenty of disadvantages in competing with the large breeder, without the difficulty of matching. We should have more fanciers, too, who buy birds simply to exhibit, because it would require less capital. Another important item—carriage, would be decreased. Judging, too, would be less difficult with one bird in a pen. Those who possess one good bird would not be excluded from showing. At many of our leading shows the single-bird system is adopted with, I believe, great success, and I hope it will soon become universal.—W. L. PEACE, *Driffield*.

HAVING seen the letters by "IMPARTIAL" and "TYNESIDE" in your Journal, I and many others are of the same opinion, that where the single-class system is carried out, it greatly tends to improve the show. Take, for instance, Thorne. Last year the entries for poultry under the double-class system were 165; this year, on the single-class principle, the entries were 276. The single class gives those a chance of exhibiting who perhaps might be unable to do so in the double class, whilst, on the other hand, it does not interfere with those who would enter in the latter.—CLERICUS.

COTTAGE POULTRY-KEEPING.

In your excellent paper of June 26th there is a short article upon the consumption of eggs, and you remark, "Anyone who traverses the bye-roads and lanes of Sussex, and sees how they are fringed with hen-coops belonging to the cottagers, learns a beneficial lesson, and would impress it as we do upon all our cottage friends." I am residing as rector in a purely agricultural village, and often and often have I spoken to my poorer friends upon the beneficial results in every way of keeping poultry. I quite believe that if only they had some such innocent and profitable little hobby as this, it would keep many a young man from evil company and the public house, &c. Many of them go lounging about, or worse, all these lovely evenings, because they have no occupation or amusement. Old Dr. Watts says, true enough—

"And Satan finds some mischief still
For idle hands to do."

But, now, what is to be done? Every person I speak to on the subject says, "Well, sir, I should very much like to keep poultry, but the farmers won't let us, and we should be turned out of our cottages if we went against them." Now, something like this has been the answer of several this week, to whom I spoke after your article upon the subject. Can anyone suggest a remedy?—Rector.

P.S.—My head gardener, who is my tenant, keeps poultry, and finds it pay.

[The farmer who is so destitute of correct feeling as to forbid a labourer keeping poultry, is a character we are so fortunate as never to have known. In the southern districts of Sussex almost every cottager is a poultry-keeper, and the farmers allow the poultry to have the free range of the fields so soon as the harvest is in-gathered. At other times they are restricted to the road-sides. It may be objected by the farmers of your district that they might then trespass on the growing corn, to which the reply is that of a Sussex farmer, "They never does any injury." The most selfish and flinty of farmers might make a contract with his labourers, that he should have a per-centage on all chickens reared.—EBS.]

BOSTON POULTRY SHOW.

THE general arrangements of this Show were excellent, and the promptitude with which the birds were penned on their arrival, and at the close of the Show despatched to their owners, merits the highest praise. The tent was very spacious, and contained specimens so diverse in character as to greatly add to the general interest of those visitors whose single object was sight-seeing. Besides a good collection of both poultry and Pigeons, the tent also contained a very great variety of Cats, Parrots, Canaries and other singing birds, whilst many excellent classes of Rabbits, and a few cages of black-and-white rats and white mice were not without their respective admirers. Another equally large tent contained the dog show, and as the weather proved fine, an extraordinary attendance of visitors was secured.

But to the poultry. Although some of the classes were exceedingly small in numbers, they were generally composed of specimens sent by the most noted breeders, and hence visitors at the Boston Show had the opportunity of seeing most of the best fowls of the day, without having to examine the accumulation of second class birds, that often tends rather to perplex than benefit an inexperienced amateur. Mr. John Robinson exhibited the only pen of *Dorkings* in the exhibition! They were a really good pair, but it is difficult to say what is the reason of the competition of late in this most useful variety of poultry having so sadly fallen off. Messrs. Lacy and Ansdell sent some remarkably

fine Buff *Cochins*, but the generality of the others betrayed that fatal objection—"mealy wings." Light *Brahmas* were decidedly poor in quality, whether as to colour or conformation. Messrs. Ansdell and Lacy sent the only two entries in the class for Dark *Brahmas*. Both these pens are well known to be excellent. It was generally regretted that the cock in the first prize pen betrayed evident symptoms of falling off from the high condition in which the owner usually exhibits his poultry. The prize pens of *Spanish* fowls were perhaps as closely competing as any class in the Show, and from their high merit attracted the attention of almost everyone. Both Golden and Silver-spangled *Hamburghs* proved first-rate, but the Pencilled ones were very deficient in quality. The *Game* fowls were certainly some of the strongest classes at the Boston Show. Mr. James Fletcher's cup pen of Black Reds were admirable, being shown in faultless condition, and certainly the truest in feather that have been seen for some time past. Some of the Brown Reds and Duckwings were likewise especially well shown. Not by any means without a vigorous competition, however, Mr. Entwisle held his own against all comers in the *Game Bantam* classes; his cup pen of Red Piles being the most faultless in colour and character that have been shown for many years past. Class 48 was exclusively appointed for *French* fowls, and the *Crèves* were singularly perfect. From some cause not easily to be accounted for, a pen of the very best White *Cochins* in the fancy made their appearance in this class, but as a matter of course were disqualified as being wrongly entered. In the Variety class, Golden *Polands* were the successful winners of both prizes. A newly-appointed class, "for the heaviest couple of live fowls, cock and hen, any breed," to the perfect astonishment of everyone present failed to enlist a single entry.

Aylesbury and Rouen *Ducks* were very superior, and in the Variety class one pen only of very well-conditioned Whistling *Ducks* constituted the entry. Both the *Geese* and *Turkeys* were very fine.

The *Pigeons* were unusually good, some of our principal exhibitors and dealers running very close races in nearly every class. The Carriers were, without exception, classes that would add much to the credit of any show. The *Pouters* were a most praiseworthy class, nearly every bird being in fine show condition. The classes for *Barbs*, *Turbits*, and *Antwerps* were such as constituted an exhibition even of themselves.

Rabbits.—The show of these was quite a success as regards their quality, as most of the noted prize and cup-winners were present. The first-prize Black-and-white was a doe of extraordinary properties, with ears measuring 21½ by 5 inches; the second was a nice Black-and-white buck, 22½ by 5½ inches; third a young buck, 21½ by 4½ inches, that will much improve with time. The very-highly-commended doe exhibited fine properties, but the ears were only 20½ by 5 inches. A high commendation was awarded to a nice doe. In this class was shown a good Grey-and-white doe, 21½ by 5½, which, had she been in her right class, would undoubtedly have taken the second prize. Only two animals were shown in the Blue-and-white class, but both were of rare quality. The first prize went to a doe 22½ inches by 5½; the second to a doe 22½ by 5½ in ear-measurement. So close was the competition that the best-matured Rabbit won. The Yellow-and-white was the grand class of the Show. The first honours were taken by a doe with ears 22½ by 5½ inches, and which has a very fine eye, good colour, nicely marked, poorly lopped. The second award went to a splendid Lop doe, 22½ by 5½ inches, fine in shape. The competition was so close that condition alone decided the prizes, the winner being shown in the highest possible condition. Third came a doe of good properties, and closely following it a very-highly-commended buck, ears 21½ by 5½ inches. Of Grey-and-whites there were two entries; the first prize went to a fine buck, 22½ by 5½; the second, from want of merit, was withheld. In *Tortoises*, the first place was taken by a magnificent doe, 22½ by 5½ in ear-measurement, shown in grand condition, taking the cup for the best Lop in the Show. The second prize went to a grand young buck, 23 by 5½ inches, very bad in colour, said to be only six months old. If no older he will make an extraordinary animal in time.

The Self colours, the largest class, contained only three Rabbits of merit, the first of which was a Blue buck, the longest-eared Rabbit in the Show, measuring the extraordinary length of 23½ by 5½ inches, good in size and shape, and perfect lop, poor eye and colour, and in bad condition. The second prize went to a buck, with ears 22½ by 5½ inches; the third to a doe 22½ by 5½ inches. Himalayans were a fair class; first came a buck of that evenness of shade so desirable; second, a very nice buck; third a buck. All the commended Rabbits were good, and their competition very close throughout. Silver-Greys were an extra good class. First came an immense doe, beautifully silvered, taking the gold medal for the best Rabbit in the Variety class; second, a remarkably fine young buck, both having beautifully silvered heads; the third-prize Silver-Grey followed closely, being in grand condition. The highly-commended and commended were good, but a little dark on the head, with beau-

tifully-silvered bodies. For Belgian Hare Rabbits, the first prize went to a very large buck, a little dark in shade; the second to a large good doe; and the third to a nice Rabbit, but too small, being only six months old. In Angoras, a doe of that fine silky character so desirable in this variety was first; the second prize was withheld from want of merit, and the third went to a fair Rabbit in good condition, but too small.

In the Any other variety class first came a good Tortoiseshell Dutch, with a perfectly-marked head and body, a little uneven in the feet, and of the old style of marking; second, a good young Dutch buck, black-and-white, evenly marked feet and head, but defective in the ring; new style of marking; third, a Dutch doe, black-and-white, fairly marked, old style. A black-and-white Dutch doe was very highly commended; grey-and-white Dutch highly commended; Ram or Patagonian highly commended; and a Siberian doe commended. A very fine Belgian Hare was passed by, being in the wrong class. The heaviest Rabbit weighed 15 lbs. 8 ozs.; second, 11 lbs. 1 oz.; third, 11 lbs.

The Rabbits, as a whole, were shown in fair condition, Mr. Ball's being in faultless condition, with the exception of his Dutch Joe, which was far too fat, being a large Rabbit, far too large for exhibition. Mr. Easton's Rabbits were shown in fine condition. Exhibitors should bear in mind that good condition is essential in close competition. There were three Rabbits suffering slightly from ear-gum and scurf, but as a whole they were the healthiest lot of Rabbits it has been our lot to look at. Great credit is due to the Manager and Secretary for the manner in which the wants of the animals were attended to. Good roomy pens were provided, and the animals well bedded with sweet hay, and fed with wholesome food. We have no hesitation in saying that they would return home to their owners little, if any, the worse of their journey.

The show pens were provided by Messrs. Turner, of Sheffield. The Judges were, for poultry, Mr. E. Hewitt, of Birmingham; Pigeons, Mr. J. Ivimy, of Long Sutton; and for Rabbits, Mr. G. Johnson, of Kettering.

Subjoined are the awards both for Rabbits and Cats. We published the poultry awards last week.

RABBITS.—*Lop-ear'd*.—1, J. Flume. 2, Messrs. Weaver. 3, J. Onick. 1, A. H. Easton. 2, W. J. Cantels. 1, A. H. Easton. 2, F. K. Banks. 3, C. King. 1, A. H. Easton. 1 and Cup, F. K. Banks. 2, Shaw & Allison. 1 and 3, F. K. Banks. 2, Shaw & Allison. *Himalayan*.—1, B. S. Rothwell. 2, S. G. Hudson. 3, J. Farrow. *Silver-Groys*.—1, M. dal, and 2, A. H. Easton. 2, S. Ball. *Belgian Hare*.—1 and 2, E. S. Smith. 3, Messrs. Weaver. *Angora*.—1, G. S. Rutton. 2, H. Clarke. *Any other variety*.—1, F. K. Banks. 2, C. King. 3, A. H. Easton. *Hearst*.—1, J. Woollet. 2, F. L. Wass. 3, E. S. Smith.

CATS.—*Tortoiseshell*.—1, H. Cribbitt. 2, E. Horner. *Tabbies*.—1, J. R. Slaton. 2, A. Reynolds. *Foreign or Long Hair*.—1 and Silver Collar, Miss E. Wright. 2, R. S. Clarke.

MR. WOODGATE'S BIRDS AT BOSTON.—As last week you published the prize list of the above Show, and in the awards put my name down as being "disqualified"—that is an ugly word under any circumstances, the facts of the case are these:—I duly entered a pen of White Cochins in their proper class, No. 38, but from some mistake of the Secretary they were entered in the French class, No. 48, and as the label only came the day the birds had to leave, there was then no time for alteration of the classes. But thinking the label had been wrongly classed by mistake, I duly sent my birds; on their arrival, however, they had a disqualified card put on their pen, and were put out of competition—rather an unnecessary proceeding, I think, seeing the mistake was entirely owing to the Show authorities themselves; but they have since behaved very well, for on my writing to them they have sent, not only the carriage expenses and entry fee, but also an extra prize.—REGINALD S. S. WOODGATE.

BARNSTAPLE POULTRY AND PIGEON SHOW.

THE seventh annual Exhibition of this Society took place on the 2nd and 3rd inst. in the large Market Hall, which was very gaily decorated with flags, flowers, &c., for the occasion. There was also a brass band in attendance, stationed near the refreshment stand to enliven the proceedings. They played various selections of music during each day, which, together with the crowing of the cocks and the barking of the dogs (the exhibition of which was held in conjunction with the Poultry Show), made a very inharmonious kind of music. Everything that could be done for the comfort of visitors was done. Seats were nicely arranged on each side of the central part of the building, while a large fountain in the middle threw its water high up and kept the edifice cool and comfortable. The gold fish placed in the large globe at the top were playing around very prettily, and gave the whole a very ornamental appearance.

The arrangement of the poultry pens was very good, but the same cannot be said for the Pigeon classes. These pens were placed above each other in five rows, the top being so high up that it was simply impossible to get a sight of the birds, and the under pens were so near the ground that people interested in the different classes had to go on their knees to see them. How-

ever, I understand this defective arrangement is to be altered next year.

There was an increase of entries this year, and the birds on the whole were much better than on former occasions, especially in some of the Pigeon classes. The feeding and watering of the birds were well attended to—a matter of very great importance to exhibitors, especially with birds sent from long distances.

There were five entries in the *Cochin-China* class, the first prize going to a magnificent pen of Buffs, and the second to a pair of Blacks. Whites were highly commended. The *Brahmas* were a larger class. First came a pen of Dark Brahmas; second a pair of Light. The whole class was good, but in bad plumage. In *Malays* or Indian Game there were fourteen entries. The Black-breasted Red Game were well represented. The Rev. G. S. Cruwys showed a magnificent pen, but they were unnoticed, although I failed to see the reason why. In Game any other variety the first prize went to a pen of good Brown Reds, the second to a magnificent pen of Duckwings. Coloured *Dorkings* were a poor class, and the first prize was withheld. There were only five entries in the *Spanish* class, but they were well represented in quality; the first-prize pen were uncommonly good, while the second pressed them closely. The highly commended birds were also splendid. It must have been a very fine point for the Judges to decide between these three pens of birds. Red-faced *Minorcas* were remarkably good; the first-prize birds were superb, and the second specimens were also fine. In *Andalusians* the prize pens were good. There were only three entries in the *Poland* class. The first prize went to Silver-spangled, the second to Gold-spangled. The other pen contained good birds, but in a very dirty condition. Golden-pencilled *Hamburgs* were one of the best classes, if not the best in the Show. Of Silver-pencilled *Hamburgs* there were but three entries, and the first prize was withheld. In the Any other variety class there was a strong muster; a magnificent pen of *Sultans* carried off the palm. La Flèche took the second prize, Crève-Coeurs the third; several in this class were highly commended. The first prize for Game *Bantams* was won by a beautiful little pair of Brown Reds, the second going to a pair of Black Reds. Brown Reds were highly commended. In the Any other variety of Bantam class, the first and second prizes went to the Rev. G. S. Cruwys for his Blacks and his well-known Silver-laced.

The *Turkeys*, *Guinea Fowls*, *Geese*, and *Ducks* mustered very well, and among them were some very choice specimens.

In the Selling classes for cock birds not to exceed £1 in price, the first prize was taken by a good Black-breasted Game, and the second by a fine young Buff Cochin cockerel. In the best hen or pullet class the first prize was taken with Black Game; a Buff Cochin was second.

In the *Pigeon* classes the first-prize Carriers were Black. The Pouter class was pretty good, but singularly enough all the birds were of one colour, White. The first and second prize pairs were very handsome, good in every respect, well bouted, of good length of limb, and good in points. Tumblers of any variety were anything but a good class; a pair of pretty good Red Mottles were first, Kites second. The Barb class was one of the best; first a pair of Blacks, second Reds. The Owl class was very fine. The first prize was well deserved by the little White African genus which were shown. Foreign Blues were second, and Silvers highly commended. The whole class was well worthy of commendation. In Fantails good Whites were first and second; Yellows and Whites were highly commended. In Trumpeters there were two grand specimens of Black Mottles, by far the best in the class; but some error occurred in the penning, yet they received an extra first prize. Turbits were a very good class; Yellows first, Blues second. Nuns were fairly represented, although trimming was discernible in some of the specimens. The Dragoon class was far from what was anticipated. A good pair of Blues was first, but the second-prize pair had too much of the Carrier's eye. The Antweps which carried off the first honours were very fine Silver Duns, although they did not look to their best, being in moult. The same exhibitor also showed a single Blue cock, which was a grand bird, the mate of which died subsequent to entry. A very good pair of Blues were second; one of them was winner of the first prize at Exeter last year. In the class for Any new or distinct variety a magnificent pair of Blue Swallows were first, Ice Pigeons second. In the Selling classes Frillbacks were first, Yellow Jacobins second. The latter ought to have competed in their own class.

Great praise is due to Mr. Northcote, the Honorary Secretary, for his indefatigable exertions; also to the Committee, in using every effort to make the Exhibition a success.—VOYAGEUR.

COCHINS.—1, S. R. Harris, Cusgarne. 2, H. Feast, Swansea. *hc*, S. W. Probert.

FLOORS OF POULTRY HOUSES.

I AM only an amateur poultry-keeper, and very inexperienced, not having kept fowls long. I had a substantial wooden house made for them, with a brick floor laid in cement; now I find they are all more or less suffering in their feet. Where have I erred?—BRENTFORDIENSIS.

[If you had consulted our "Poultry-keeper's Manual" you would have saved yourself much trouble; there you will find the following:—

"Bricks or pavements of any kind we regard as the worst of all materials for the floor; they retain moisture, whether atmospheric or arising from insufficient drainage; and thus the temperature is kept low when warmth is most essential, and disease too often follows, especially rheumatic attacks of the feet and legs. The flooring of a poultry-house should be of dry gravel, and quite loose to the depth of 2 or 3 inches—nothing can then adhere to it; and it is neither necessary nor right to sweep the floor of a poultry-house. A long birch or heath broom may be drawn lightly over the surface. It will remove everything that offends, but if turned over with a spade twice or thrice weekly, the earth decomposes the dung and becomes a good fertiliser in the course of a few months, and has then to be removed and replaced by fresh earth. A mixture of gravel and coal ashes makes an excellent flooring, and in which the fowls delight to busk."—EDS.]

BEES' HATCHING TIME.

MR. PETTIGREW says, on pages 41 and 43 of his book on bees, "Generally the eggs for young queens are set about four days before swarming takes place," and that those eggs will produce "beautiful princesses in ten days," which would make together fourteen days from the time the eggs were set. Now, on Sunday, June 15th, I hived a first swarm, and in about ten minutes it returned to the parent hive; on Tuesday, June 17th, it swarmed again, was hived as before, but returned again to the parent hive. To-day (June 27th) it again swarmed, and is now permanently hived. I want to know from which date I must reckon the ten days, or whether I must take no notice of the swarming on June 15th and 17th, and consider this of to-day (the 27th) as the commencement.

Mr. Pettigrew also states on page 145, that "on the twenty-first day after the first swarm leaves a hive the combs are free from brood, save a few drone cells." I want to be informed from which date—viz., 15th, 17th, or 27th, I must reckon the twenty-one days, in order to find no young brood in the above hive.—GERTRUDE.

[Mr. Pettigrew very wisely uses the word "generally" when speaking of the development of "the eggs for young queens." Everything in this case depends upon circumstances. We have known eggs lie dormant many days before the hatching took place. Much depends on the activity of the bees themselves, which proportionably increases the temperature of the hive, on which hangs so much of its prosperity in every way. Therefore, in answer to your query, we say with Mr. Pettigrew "generally," or perhaps more correctly "under favourable circumstances," the young queens will come forth about the time specified. But here again there comes another qualification. In the case of wet or stormy weather, which in our variable climate sometimes lasts a fortnight or more even at the prime of the year, the young princesses may be prevented from issuing from their cells by the wise forethought of the bees, even though fully developed. It is therefore quite impossible to date precisely the issue of the young queens from the setting of the eggs; but we

should be inclined to take the earliest date you have named, allowing for all sorts of casualties. We have known swarms issue before any eggs had been laid in royal cells; we became aware of this by subsequent examination, as we found "artificially" formed cells, and only such in out-of-the-way parts of the comb.]

OUR LETTER BOX.

BOSTON SHOW.—Mr. W. Woodhouse informs us that he took the first prize in "Tumblers, any variety," with a Blue Baldhead cock.

GAPES (Brahma).—The plan you mention is in all old poultry-hooks. It is a difficult operation and very uncertain.

EXHIBITION PENS (F. B.).—We do not think you can do better than use Mr. Turner's pens of Sheffield. They are very good, and he sends an experienced man with them, who is very useful. You can put yourself in communication with him. We know no one in Bristol. You want troughs only for water. Put sand or gravel on the floor, and throw the food upon it. (F. B.).—We know no place where you can hire pens, except of Mr. Turner, of Sheffield. We think well of them, seeing them often.

LIGHT BRAHMA CHICKENS (R. E. H.).—We give our chickens no Indian corn. It is not good for growing chickens. It does not make bone. We should at once discard pea and Indian cornmeal. Ground oats are in use throughout Sussex, and we have bought them of Messrs. Marsh, Market Place, Kingston, Surrey. Try barleymeal, and mix some dripping with it. Give them meat scraps from the table, and curd made of new milk turned with rennet, and dried by two persons turning a cloth opposite ways.

TURKEY POULTS SICKLY (J. P.).—Are your Turkey poults at liberty? If they are, the probability is the hen dregs them about through dewy or frosty grass till they get chilled. Shut the hen up in a rip—an empty china crate is a good one, with a thatched hurdle to keep off the wind, and another on the top to keep off the rain. If as convenient or more so, you may shut them in any out-house, but they should not be let out till the sun is well up, and the grass dry. Give them some ants' eggs if you can. Feed them on oatmeal with which a small quantity of pea and beanmeal is mixed, and chop-up some onion-tops with it. You may safely give the sickly ones a pill of camphor the size of a garden pea.

COCHINS' FEATHERS COMING LIGHTER (A. Y. Z.).—You cannot prevent the hens from moulting light. You are not safe in interfering with the moulting process. Let Nature have her way, and all be well.

"From Nature's chain, whatever link you strike, Tenth, or ten-thousandth, breaks the chain alike."

GROUND OATS (H. J. L.).—The sample you sent is of crushed oats. Ground oats are as much a powder as is barley meal. The only person whom we know to prepare ground oats is Mr. Azate, Slough Mills, near Crawley, Sussex.

CANKER IN PIGEONS (A. Suberbiok).—A great authority stated in this Journal, that of all things do not attempt to cut the canker out, but dress the place twice a day with a solution of zinc or copper (use the crystallised), about half an ounce to a quart of water. Merely wash the bird's mouth, or wherever the sore is, with a flint feather. The lotion must not be too freely used in the month, a very little is quite sufficient.

FEAS IN A PIGEON LOFT (Bird's Egg).—You have, doubtless, limewashed the place thoroughly. Allow no dust, or feathers, or dirt to lie about. Clean out the corners. The Persian insect powder will do good.

LABRINIANS (J. Mackenzie).—We have no reason to think that you will be dealt with unfairly.

BEES PROFITABLE (Rev. S. A. Brennan).—Bees are profitable, as we can testify from experience, and cent. per cent. is quite within the mark. But where to find a market for honey gathered in Co. Tyrone we cannot state. You are too far from the great market of London to get the high prices which are obtained there, 2s. or 2s. 6d. per lb. But if you got no more than 1s., the profit would still be cent. per cent. on a well-managed apiary. Have you no market in Dublin?

BEES NEAR CARDIFF (Bird's Egg).—The suburbs of Cardiff ought to be no bar to your success in bee-keeping. You must be sufficiently near the open fields to have a fair chance. They have succeeded even in Hibernia. We fear it is not generally a good honey year; but the flowers are late, especially the white clover, which is a grand honey-producing flower. There may still be three splendid weeks in July. But it is impossible to predict. The secret of success in bee-keeping is to have strong stocks and swarms, and to give your bees plenty of room. What sort of hives are you using? and what spurs, if any? Tell me how this we cannot advise when or how to "take it off."

BEES CLUSTERING-OUT (C. M. Major).—It is almost too late in the season for swarms to do much good, or we should advise your driving out all the bees of your cottage hive into an empty butt, which is to be left on the old stand. The Neighbor's hive should then be moved to another part of the garden, and the hive from which the bees have just been expelled be put in its place. The bees returning will, with those rapidly being hatched out of the cells, make a good stock, and will raise royal cells. Taking the advanced state of the season into consideration, we should be inclined to recommend either fixing the hive on a nail, or else, or cutting out a 4-inch hole in the top, lining on with a ring of soft putty, a board of suitable size, clamped at the ends to prevent warping, with a 3-inch hole, and giving the bees a super. The bees outlying would soon go up, and even if they do not fill the super before winter, some combs may be built which will be useful the following season. Bees clustering out in this way without swarming, proves that the hive is not ready or disposed to go. In such cases the bee-master should prevent such waste of valuable bee time, by compelling them to swarm as soon as they begin to cluster out. You will need no personal advice if you have any of the works published relative to bee-keeping.

WAXEN (Noriel).—Queries 1, 2, 3, 4. White deal will do for hive-making, but better is not deal. Screws are the best fasteners. Bees do not like zinc used as a plate such as you have in view. 5. Can any of our readers say where machines for the manufacture of straw hives can be procured? Or will anyone kindly furnish a drawing of such? We think you might make one easily with a little ingenuity to suit the size and shape you wish to give your hives. C. No. 7. No. 8, 9. Dr. Dugbar has been dead many years; so has Mr. Golding. We know not where their books can be bought. Can any of our readers tell us? 10. Dr. Bevan's original work is now out of print. It has been recently edited by Major Munn, but we question if our old friend Dr. Bevan would own the work now published in his name, so many have been the alterations introduced, and the liberties taken with his almost exhaustive treatise. 11. We do not know Dr. Mackenzie's work on bees. 12. Perhaps Mr. Pettigrew can tell us "what are the dimensions of the largest straw hive that a good

queen would be capable of filling in a good season." We have only tried such a hive as would hold a bushel of wheat or a little more.

BEEES CLUSTERING-OUT BUT NOT SWARMING (J. Badger).—You will find an answer to another correspondent which meets your case.

CAT (P. M. R.).—We could not publish an answer. Ask any veterinary surgeon.

NEWFOUNDLAND PUPPY (Canine).—The symptoms are some of those which characterise the distemper. Give five grains of blue pill, and five hours after a table-spoonful of castor oil. Foment the eyes by means of a sponge with a decoction of poppies. This disease has too many complications for us to analyse further. If the dog declines in strength he will require tonics, but consult a veterinary surgeon, or buy Merrick's little book on "House Dogs and Sporting Dogs," and follow his directions.

SILK FROM SILKWORMS.—"K. E. B." asks, How should the silk be wound to make it available for use? There must be an immense amount of wasted silk among the thousands of silkworms kept by young people, and many would be glad to make the amusement a useful one. When suitably wound where would it be disposable?

[We shall be much obliged by information in reply to the above.]

METEOROLOGICAL OBSERVATIONS,

CAMDEN SQUARE, LONDON.

Lat. 51° 32' 40" N.; Long. 0° 8' 0" W.; Altitude 111 feet.

Table with columns: DATE, 9 A.M., IN THE DAY, and Rain. Rows include 1873, July, and various weather observations with temperature and wind data.

REMARKS.

- 2nd.—Rather cloudy morning and evening, but very fine in the middle of the day.
3rd.—Dull morning; fine at noon, clouding over in three or four hours; sharp shower at 8 P.M., then fine.
4th.—Thunderstorm at 2 A.M., fine after; rather cloudy about noon, then fine, but two or three slight sprinkles of rain; a fine evening and night.
5th.—Showers in morning; fine afternoon, but still not summer-like.
6th.—Much rain in the night, but a lovely day after the morning.
7th.—A beautiful summer day, and splendid moonlit night.
8th.—Much warmer, and a very fine day, though rather cloudy at night.
Mean temperature much the same as previous weeks; but the range somewhat greater, the maxima being higher and the minima lower.—G. J. SYMONS.

COVENT GARDEN MARKET—JULY 9.

We have nothing fresh to report.

FRUIT.

Table listing fruit prices: Apples, Apperotts, Cherries, Currants, Figs, Filberts, Gooseberries, Grapes, Lemons, Melons, Mulberries, Nectarines, Oranges, Peaches, Peas, Pine Apples, Plums, Quinces, Raspberries, Strawberries, Walnuts.

VEGETABLES.

Table listing vegetable prices: Artichokes, Asparagus, Beans, Broad-beans, Cabbages, Caper-squas, Carrots, Cauliflower, Celery, Coleworts, Cucumbers, Endive, Fenel, Garlic, Herbs, Horseradish, Leeks, Lettuce, Mushrooms, Mustard & Cress, Onions, Parsley, Parsnips, Peas, Potatoes, Kidney, Round, Radishes, Rhubarb, Salsify, Savoy, Scorzona, Sea-kale, Shallots, Spinach, Tomatoes, Turnips, Vegetable Marrows.

POULTRY MARKET—JULY 9.

We have still a small supply, and the demand is quite up to the average. These prices can no longer be depended upon.

Table listing poultry prices: Large Poultry, Smaller ditto, Chickens, Goslings, Green Geese, Ducklings, Pheasants, Partridges, Hares, Rabbits, Wild ditto, Pigeons.

WEEKLY CALENDAR.

Day of Month	Day of Week	JULY 17-23, 1873.	Average Temperature near London.			Rain in 43 years		Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.	Clock before Sun.	Day of Year.		
			Day.	Night.	Mean.	Days.	m.	h.	m.	h.	m.	h.	m.	h.	Days.				m.	h.
17	TH	Royal Horticultural Society's Polargonium Show closes.	74.3	51.3	62.8	16	5	af	4	7	af	8	38	11	22	1	23	5	50	198
18	F		74.7	50.2	62.5	21	6	4		6	8	57	11	42	2	24	5	54	199	
19	S	Clackheaton Horticultural Show.	73.2	49.9	61.1	23	7	4		5	8	morn.		2	1	25	5	58	200	
20	SUN	6 SUNDAY AFTER TRINITY.	73.2	50.2	61.7	22	9	4		3	8	22	0	18	5	26	6	3	201	
21	M		74.0	50.8	62.4	19	10	4		2	8	54	0	26	6	27	6	6	202	
22	TU		72.2	51.4	61.8	21	11	4		1	8	38	1	23	7	28	6	8	203	
23	W		74.0	51.4	62.7	21	13	4		0	8	32	2	7	8	29	6	10	204	

From observations taken near London during forty-three years, the average day temperature of the week is 73.7; and its night temperature 50.7. The greatest heat was 94, on the 17th, 1834; and the lowest cold 32, on the 23rd, 1863. The greatest fall of rain was 1.37 inch.

AT A ROSE SHOW.

WONDER if these few notes will be accepted. If they are, so much the better; if not, no harm done.

I have recently been exhibiting at several Rose shows, and thought I would send a few lines descriptive of the delights of showing to our most excellent JOURNAL OF HORTICULTURE. I know not what is pleasanter or jollier than taking one's blooms to one of the great shows. From first to last it is to me an unbroken pleasure. Even the early rising, the jumping out of bed at 3 A.M., when all the rest of the world are fast asleep, is pleasant; for you know what a glorious sight you will presently have. When dressed and out of doors, how lovely your Roses look! every petal frosted with dew, every leaf glittering with moisture; and whilst cutting your finest blooms and staging them, how grand is the sight that gradually unfolds itself! The sun rising in a quiet summer's morning, the eastern horizon at first suffused with rosy light suddenly changed to the brightest of ambers, and, before you have half done your work, with one leap the sun has risen.

Then the journey to the show, how pleasant it is! Even the railway people at your own station, how pleased they seem to see your boxes, and how willingly they help you to put them carefully into the guard's van; and when you come to a junction, and some friend whom you knew would meet you there, appears with his bright green boxes, how delightful the meeting. And here let me tell a short anecdote. Two nurserymen were overheard talking at a show about myself and my great (and, alas! generally victorious) Rose rival. "Yes," one said, "they always show at the same places, and yet they are friends." "Aye," said the other, "and I have heard, and I believe it is true, that they visit each other's houses." Then the next morning, when we arrive at the tented field, to see the hundreds of Roses being prepared, what a grand sight it is, and how real lovers of the Rose delight in it! Think of being placed near one of the great Rose monarchs—a Paul, a Turner, or a Keynes, and others! You can see him stage, and observe, without anyone to crush you, or policeman to shout, "Please pass on," to what a state of perfection each Rose, so familiar to you at home, really can be brought; and most delightful of all, because most flattering, sometimes to be asked by the cultivator of tens of thousands which of three blooms you would say was the best for his seventy-two.

And when your own boxes are ready for the judges, and just before the tent is cleared, how can words describe the scene which we are privileged to see? The great nurserymen's boxes all uncovered, each bloom a picture, every Rose we have tried to bloom at home here shown at its best, everyone we have longed to see, shown in trebles and singles. Morren, Castellaine, Nicol, Amand, &c., all shown without a spot on their petals, and perfect as to form and colour.

And now we leave, but not for long; soon we shall be

re-admitted, and then we shall know our fate; and in the meantime there is a very satisfactory way of spending our time. We are as hungry as horses, and just as we are thinking of breakfast a hearty voice shouts out, "Come and breakfast with me, old fellow," and our great rival, the king of the amateurs, lays hold of us, and carries us off to his hotel; and there we talk of our chances over the best of breakfasts, with, perhaps, a glass of champagne to keep up our spirits, and before we have well done it is time to rush off to the show again. We present our pass, we enter the tent, we make to our boxes, and then—well the writer of these lines was successful; but if he had not been so—and he often has not—he would enjoy it nearly as much, and at all events would have congratulated his friend as heartily as he in turn was.

But we have not done yet with the delights of the show. What pleasanter to stand near your box and hear the remarks the visitors make upon your blooms? Sometimes they are flattering, sometimes the reverse, and now and then wonderfully cruel. "I could have shown much better blooms than that." "If I had known there were no better Roses to be shown, mine ——" "Pass on, ladies and gentlemen, pass on." "I wish you would pass them on, constable," says a rather portly old woman, "for they have been pushing me all round the tent like a catapult." Then the meetings of friends, and the introductions to people whose names are as familiar to you as the flowers that they grow. The pleasant greetings, among others, of your old friend and correspondent, "D., Deal," and the valuable information he imparts to you on this year's new Roses which he has seen exhibited for certificates at Kensington. In fact, there is no pleasanter place than a Rose show, there are no better fellows than the exhibitors of Roses, whether they be amateurs or nurserymen, and there is nothing which delights me more than the conviction that each year the Rose is more popular, and the exhibitors more numerous.—JOHN B. M. CLARK.

TRACHELIUM CERULEUM.

ALTHOUGH *Trachelium ceruleum* has been cultivated in this country for more than two centuries, it is far from being generally known. I have frequently met with persons whose knowledge of the plants of the day extended to countless varieties of each species, but who acknowledged their ignorance of this handsome plant.

It is a native of the south of Europe, and though moderately hardy, it suffers from unusually severe winters, therefore it is desirable in most cases to preserve a plant or two under glass; but it is easily raised from seed, and seedlings flower the same season. Allied to the *Campanula*, it, nevertheless, differs from the most of that genus in its habit of growth; it does not throw up suckers like most of that family, but produces side shoots, which make excellent slips or cuttings. It also differs from most of the cultivated *Campanulas* by its flowers being collected into a flattened umbel, often 5 or 6 inches across. Although the individual flowers are small,

they are very numerous, and in colour a rich violet blue in some plants, while in others they are of a bright lavender, and I have occasionally had plants with white flowers. The latter, however, are not so desirable as the darker-tinted kinds, excepting for the sake of variety. The height is about 2½ feet, and few plants present such a mass of bloom as this, and still fewer of the ordinary herbaceous plants remain longer in beauty; while in dying-off it never presents an untidy appearance, for the flower-stem looks well to the last, and when removed a neat plant is left, more or less plentifully supplied with shoots, from which slips or cuttings are easily obtained. These, if put into a cold pit or under a hand-glass, where some protection can be afforded them in winter, make good plants in the following spring. We often put in a batch of cuttings in September at the same time as Pentstemons, Santolinas, and even Centaureas, and they rarely fail to strike.

Our plan is to insert the cuttings in rows in a cold pit in sandy soil, and to shade them for a time if necessary, but always giving them the benefit of the heavy dews that are common then. The plant, as already stated, is also freely propagated by seed, which, however, requires to be sown in pots or pans, as it is very small—perhaps one of the smallest of all garden seeds, being much smaller than that of the *Calceolaria* or *Lobelia*; but it is obtained in any quantity, and I have raised seedlings in the open ground often enough. Seedlings, I need hardly say, make the sturdiest plants, besides giving the chance of variety, but a few cuttings insure a continuance of a favourite kind, and, besides, there is some uncertainty in so minute a seed being lost in the ground, or the young plants falling a prey to insects or other enemies, so it is desirable to secure a stock from cuttings.

I have sometimes grown the plant in rows along with other herbaceous plants of similar habit, as *Phloxes*, double *Rockets*, and *Catchflies*. It likewise makes an excellent plant for the mixed border; the question, "What is this?" being often asked when its numerous heads of flowers form a sort of balloon or beehive, and this, too, without the aid of sticks or artificial support. It is also sometimes met with as a pot plant, and supplies a colour not at all plentiful in the conservatory. I am not partial, however, to growing anything in the conservatory that will succeed out of doors, unless it come in at a particular season. To those who are not acquainted with it I unhesitatingly say, Procure it at once; they will not regret the adoption of my advice.—J. ROBINSON.

POTATO PROSPECTS.

I OBSERVED a statement in the *Journal of the 3rd Inst.*, on the authority of the *Yorkshire Gazette*, that the Potato disease had appeared in North Yorkshire, and that the early American kinds were most affected. Last year the early American kinds, especially *Early Rose*, were free from the disease, and happy should we be had we no greater disease to contend against than that which has shown itself in the June of the present year in the early American kinds in North Yorkshire. The disease to which our north-country papers refer is what is known all over the country as the curl, which has no relation to the Potato disease that begins at the haulm and then attacks the tubers.

The American *Early Rose*, though not quite free from disease last year in North Yorkshire, was the least affected, excepting *Red-skinned Flourball*, which was quite free of disease. This year *Early Rose* has been much affected with curl, a disease quite as virulent as that which attacks the Potato at a more advanced stage. The curl presents itself as soon as, or very shortly after, the haulm is above ground. What is it but the undecayed growth of a diseased tuber, the consequence of planting a diseased set? Did you ever try to get a crop of Potatoes by removing the set as soon as the haulm was a few inches above ground and note the result? No Potato affected with curl comes to anything; no Potato from which the set is early removed produces a crop, for in both cases the plant is deprived of the support which it requires. Even a diseased Potato will make an effort to continue its kind if the eyes be not destroyed, but the growth is weak.

Now that we have to deal with the curl, permit me to say that I last autumn pointed out that the Potato disease is not hereditary, and cannot be reproduced either by planting a diseased Potato or by contact with diseased haulms or tubers. Plant a diseased tuber with sound eyes, and it will grow weakly; the haulm and the whole haulm will be speckled with dark brown spots. The curl will be manifested by the leaves curl-

ing; and the plant, if the set has not been much diseased, may make an effort at flowering, but sound though small tubers, capable of continuing their race, will be formed. The disease has been thrown off, and will not again return until the plant be in a fitting state for the development of the spores of the Potato fungus. It will be found in most cases that the Potato plants infested with curl have the sets partially or wholly decayed; but the curl, though generally resulting from a diseased tuber, is not always to be traced to that beginning. The removal of the sprouts once or twice before planting, after allowing these to grow several inches long in "pies" or "hogs," or on dry shelves or floors, is a taking-away of the life-blood of the set, and to such an extent is this sometimes carried that many kinds, especially the earlies, do not make a second growth after being planted, or if they grow, the growth is weak, and they begin to form tubers early. They then curl up their leaves as all Potatoes do when forming tubers, and growth is at an end, simply because the set can afford no more support. To have sound full crops we must plant plump, healthy sets.

I may remark that Potatoes in Cleveland present a very healthy appearance. In gardens, though admitting the curl in the early American kinds, especially *Early Rose*, which, in my opinion, has no claim to special mention, I have not seen them finer. We have taken up *Ashleaf*, *Myatt's Prolific*, and *Veitch's Improved Ashleaf* from the open ground, and they are fine and dry, even floury when cooked; and the later sorts, of which I have upwards of twenty, are very promising, especially *New Hundredfold Fluke*, *Red-skinned Flourball*, *Late Rose*, *Excelsior*, and *Willard's*, the last three American sorts. I may also mention that Potatoes come from self-sown seeds here. We have cut and pulled up thousands within the last few days. They came up even on trenched ground; the kind is evidently the old *Pink-eye*, a variety of the finest quality. In the fields the Potato crop promises well, especially where a change of seed had been secured.

The disease mentioned by your excellent correspondent Mr. Bichant in No. 639 as occurring in an orchard house, was, I grant, the disease proper. It would be interesting to know if the Potato haulms were syringed after they had attained their full growth and when tubers were forming, or if the trees were. Was not the haulm of the Potatoes wetted twice a-day? From the cold of the past spring and early summer it is likely the house would be kept closer than usual. I had similar experience in a vinery. All went well until the haulm was full grown; then, from syringing the house, the haulm was wetted, and it was clear that either the foliage of the Potatoes must be kept dry or the crop would fail. They were not wetted, and the crop ripened, but not well. In houses and in frames I have not had a diseased tuber where the plants were not wetted overhead after the tubers were well advanced, but kept only moist at the roots. Continued dampness of the haulm of Potatoes when ripening deteriorates the quality of the tubers, and generally results in disease.—G. ABBEY.

GREENHOUSE GLAZING.

I HAVE practised the method described by "J. P.," of York, in your number of July 3rd for several years past, and I question if any of the patent processes will bear comparison with it for cheapness and efficiency; in fact, a more simple, inexpensive, and neat method could scarcely be devised. Your correspondent very accurately describes the *modus operandi*, which, however, I think I can slightly improve upon in one or two particulars. In the first place an eighth-of-an-inch play on each side of the glass is too much. If the rafters are put quite true, and the glass cut true, an eighth of an inch will be ample space to allow for expansion of rafters, which, I may remark in passing, is never so much as is generally supposed; in fact, if the glass goes in easily and freely all will be well. Then, again, if large panes are used (mine are all 12 by 20) a tack will be required on each side at the end of the pane to prevent its slipping down, and another close to it at the extreme point of the lower corner (not upper, as described by "J. P.") to keep the glass in its proper place; thus one tack holds both panes. Nothing is better than long tin tacks. I am confident that no one who gives the plan a trial will ever return to the old system of facing-off with putty.—WILLIAM WINDMANN, *Bevois Mount Nursery, Southampton.*

THE AUCUBA.—It is probably not known that the male plants raised from seeds of the old female *Aucuba* come into flower

at the same time as the old females, whereas imported or purchased males flower considerably earlier. This has been found here, without exception, to be the case, and is looked upon in these gardens as a valuable discovery.—G. H. COOK, *The Gardens, Penarth, Merioneth.*

FORCING THE ROSE.

Most varieties of the Rose are capable of being forced; but the Hybrid Perpetuals are much to be preferred as a whole, and it is of them that the great bulk of our stock is composed. A few of the old Cabbage and common Moss Roses are desirable on account of their fragrance and delicate colours—besides, the Moss makes the finest button-hole Rose; they are also both very prolific bloomers. A few also of the summer-blooming Roses are indispensable, such as *Coupe d'Hebe*, Charles Lawson, Paul Ricaut, Maiden's Blush, and a few others. But it is among the Hybrid Perpetuals that the grandest Roses are to be found and the greatest variety selected. *Baroness Rothschild* is a magnificent light-coloured Rose for forcing, and a strong grower; *Duke of Edinburgh*, a dark Rose, also fine; *La France*, a superb Rose; *Miss Poole*, *Jules Christin*; and of older Roses, *Jules Margottin* is very prolific; *Sémateur Vaisse* and *Général Jacqueminot* are two old Roses of fine scent and colour; *Souvenir de la Malmaison* is a sure and distinct Rose; but selection is scarcely possible; they are nearly all equally suitable—at least we find them so. Many of the Tea-scented Roses are also first-rate for forcing, cutting them when just about to open. It is needless to name varieties, as the whole of them are suitable for pot-culture. If plants are received from the nursery they must be examined at the roots to see if drainage is all right and the soil in a healthy condition. Any plants with the pots full of roots should be shifted at once; those not demanding shifting should remain until some growth has been made, standing the plants in a cold pit for a time with plenty of ventilation.

By the first week in June, when the sun is getting hot and powerful, they should be plunged in the full blaze of his rays out of doors. This is the time when we repot all our stock of pot Roses; till the first week in June they have been resting after the flowering period, attention being paid to them in watering and not overcrowding them in some sheltered place out of doors. Those in small pots are shifted on if the pots be full of roots and the soil healthy; others may require partial shaking-out and repotting in the same sized pots; none of them are in larger than 11-inch pots, which is large enough for early-forced Roses, and fine large plants can be grown in pots of that size. We do not cut or prune Hybrid Perpetuals at this stage, believing that they should have all the foliage left to ripen the wood and enable them to make roots; much fresh growth after this is not desirable on Roses to be forced early. We, however, cut out any old exhausted wood from the Tea-scented Roses.

The Rose in the open ground thrives best in strong loam whose basis is clay; for potting, however, a lighter open soil is to be preferred: a light, yellow loam of a sandy texture is what we use, well-enriched with rotten farmyard manure. Light manures, such as leaf-mould or old mushroom-bed dung, are not of much use for Roses—they like more substantial fare. The soil should be chopped up rough, and a sprinkling of crushed bones will much improve it, and a few over the cracks will serve the double purpose of drainage and manure, which the roots soon find out. Pot firm, and drain well. When firmly potted the soil is not so liable to become waterlogged, or the drainage disarranged. Roses want a deal of water in the summer. When all are potted as they require, arrange the plants in rows according to size—the tallest at the back, and giving room to those which require it, without any attention as to the distances being uniform—in a turf pit facing the sun, in a warm sheltered place, and fill-in between the pots with sawdust, which keeps the roots equable as to temperature and moisture. The sawdust absorbs the heat of the sun through the day, and Pine-wood sawdust is also obnoxious to worms when it is fresh. Here they will now require very little attention throughout the summer, except watering, and an eye to suckers from the stocks if the Roses are worked plants. Those known to be well-rooted should have weak liquid manure at all times when watered. We sometimes top-dress the whole with sheep's or other dung, as it is useful at a rainy time. When the water-pot is not required, the rain washes the manure into the soil. All flower buds are picked off the plants as they are formed, and sometimes a few plants may require staking, but

not often, unless a strong shoot gets top-heavy, catches the wind, and unsettles the whole plant in its pot. About the end of October we remove the whole to the Peach cases, where there is abundance of air night and day. Here they are allowed to become comparatively dry at the root, when the foliage will soon begin to turn yellow and fall off, a sign of ripeness of the wood. Water may now be withheld entirely.

By the middle of December they may be pruned. This we do to the whole at one time. It is not at all necessary to leave those unpruned which are required later. They will start as required, just as Vines in pots will. The difference in flowering is effected by the time the plants are pruned, but by this time they get introduced into heat. The first lot may be selected and started at once; the most mild temperature of a Peach house just started suits them well. Here they will have the syringe daily, and for a time plenty of light, and a minimum of fire heat. If a low span-roofed forcing house can be devoted to them, so much the better; they can be better attended to as regards ventilation, and will have the benefit of all the sunshine possible, better than under Vines or Peach trees. One good soaking of water will be sufficient for a time; the syringe will keep them moist enough until they have developed a foliage. The chief points to be attended to now will be to husband the sun's heat, to ventilate freely when the weather will allow, but avoid draughts, which will injure the tender foliage and induce insects. The object must be to get strong growth; spindly drawn growth ruins the plants for future use, as well as yielding poor unrecognisable flowers. Fumigate on the least appearance of aphid, and watch for the Rose grub, which curls up the leaves and eats out the buds. Force slowly with as little fire heat as possible, the thermometer ranging from 50° to 65°, or 80° with sun heat.

The plants must be gradually hardened before removing to a cool house, else the buds may turn yellow and drop off. If the conservatory be warm they will not feel the change, especially if the forcing has not been rapid, and the pots not been plunged in heat. Water with liquid manure as soon as the buds begin to show, and continue until all the flowers are out, after which the same routine of ripening, and resting, and potting begins for another year.—THE SQUIRE'S GARDENER (in *The Gardener*.)

THE NEW STRAWBERRY DWARF TOMATO A DECEPTION.

AMONG the announcements of vegetable novelties for the present season there appeared the following taking description of a "New Strawberry Dwarf Tomato!"—"An entirely distinct variety, of novel form, and totally different in appearance to all other Tomatos. The fruit has a juicy pulp of a pleasant Strawberry-like flavour, with a certain degree of sweetness and acidity. With the addition of lemon juice it is frequently preserved like Plums, as well as stewed like Cranberries, if kept from the frost till spring." To give still greater force to this announcement, it was further stated that the variety, with some others, had "been recently introduced by us from America, and can be highly recommended." Like many other gardeners I gave sufficient credence to a statement so attractive, and hearing such an appearance of truthfulness, as to order a packet of the seed—not of the introducers, but of another leading and highly respectable firm, who were deceived equally with myself. The seed was sown, the plants raised and cultivated, and the result is that the so-called novelty proves to be—not a Tomato, but our old friend *Physalis edulis*, the Cape Gooseberry! Now, the cost of the seed and its cultivation was so trifling that one would hardly be at the trouble of complaining if nothing more were involved, but it is the feeling of distrust that such faulty practices engender that is most to be deplored. Willingly do I ascribe to enthusiasm the highly-coloured, often-exaggerated descriptions which herald the advent of many new plants and flowers; but when an old plant is pressed under a new name upon the public, it becomes a matter of duty to expose it and all such practices.

It is always painful to publish strictures of this kind, and I venture to hope that the matter may be explained to the satisfaction of all concerned, on this side of the Atlantic at least.—E. LUCKHURST.

PROPAGATION OF THE MISTLETOE IN WALES.—Two years since some seeds of the Mistletoe were rubbed upon, not inoculated into, an old Apple tree here, a large original Ribston Pippin. Last year the only symptoms of vegetation which any of these

seeds showed was throwing out two or three "tentacula," or claws; but this year one of the seeds has vegetated, and has now thrown out sprouts of more than an inch long. It was quite despaired of that the seeds would vegetate. This information may be useful to anyone who may wish to propagate this parasite in our, as in many other districts almost unknown.—G. H. COOKE, *The Gardens, Peniarth, Merioneth.*

FLOWERS FOR OUR BORDERS.—No. 10.

POTENTILLA MENZIESII.—MENZIES' CINQUEFOIL.

THE order Rosaceæ, to which the genus *Potentilla* belongs, may be regarded as one of the most important of the vegetable kingdom; for it includes within its limit not only some of the handsomest of our garden flowers, but also comprehends all the most valuable of the fruits of the temperate regions, such as the Apple and Pear, and the different varieties of the Peach, Plum, Apricot, and Cherry. Leaving aside, as foreign to our present purpose, the fruit-bearing genera, we may claim for the *Potentillas* a high rank among the ornamental plants of the order.

Of the 150 species and varieties known, all, with scarcely any exceptions, are interesting plants, and a considerable number of them are indeed scarcely inferior in beauty to any of the hardy perennials.

Most of the highly-coloured varieties now so common in gardens are hybrids; the flowers of the wild species being, with very few exceptions, yellow or white.

Among those species most deserving of cultivation may be named *P. rupestris*, with pretty pure white flowers produced in May; *P. pyrenaica*, also an early bloomer, of dwarf habit, yielding bright yellow blossoms in profusion; *P. mollissima*, with primrose yellow flowers; *P. Richardsonii*, also yellow, with foliage silvery beneath; *P. atrosanguinea* and *P. formosa*, two Nepalese species, the former with deep purple, and the latter with pale cherry-coloured flowers. These two species are not only interesting for their intrinsic beauty, but also as being the parents of many of the numerous hybrids which have adorned our gardens for years past. As one of the earliest and best of these we may name *Russelliana*, formerly a very popular plant, but now superseded by varieties with greater breadth of petal and brighter colours, of which *P. Menziesii* may be regarded as the type. Equally desirable are the varieties *Hopwoodiana*, *Macnabiana*, *Smontii*, *Striata multiflora*, all more or less distinct in colour. But beautiful as these are, they are eclipsed by the numerous double and semi-double varieties of recent introduction, which have the advantage of not closing their flowers so completely as the single-flowered, and their blossoms are also of longer duration. Some of the best of these are *Louis Van Houtte*, large, deep crimson; *Belisaire*, bright vermilion; *William Rollison*, reddish yellow and orange; *Rosaflora plena*, rich velvety vermilion, edged with yellow; and *Vase d'Or*, canary yellow, all first-class plants, worthy of being added to the most select collection of perennials.

All the species and varieties we have enumerated are perfectly hardy, and of the easiest cultivation, though it cannot be said that they will flourish in any description of soil. They succeed best in a good rich earth of some depth, and require, in summer, a plentiful supply of water, especially about the time the flower stems are thrown up. We have never seen the *Potentillas* grown in beds, but we think that such an arrangement would be exceedingly interesting, if a proper selection of plants were made. For the centre of the bed one of the shrubby species, such as *fruticosa*, or *floribunda*, both with yellow flowers, and growing about 4 feet high, would be well adapted; and around these might be grouped the erect-growing herbaceous species and varieties, reserving the trailers, of which there is a fair sprinkling, for the outer circle.

They are all readily increased by dividing the roots early in spring, and as these descend to a considerable depth, care must be taken that the fibres are not broken. Many of the species ripen seeds, from which new varieties may often be raised, and all the seedlings would flower the second season after sowing.

A wide field is here open to the amateur florist, and, with a little care and attention, he could scarcely fail to originate some valuable additions to this ornamental family.

There is an allied genus, of which a few species are occasionally found in gardens, and which fully equal in beauty the *Potentillas* we have named; we allude to the *Geums*. They are distinguished from the *Cinquefoils* by their lyrate leaves,

reflexed calyx when in fruit, and more particularly, by the style of the numerous little granular seed-vessels being jointed. (*Geum coccineum* (the *G. Quellyon* or *chilense* of some authors), is an extremely handsome plant.

The properties both of *Potentilla* and *Geum*, as well as of *Tormentilla*, another allied genus, are very similar. Many of the species of the three genera are astringent and aromatic, and all are perfectly innocuous. The common *Potentilla anserina*, or Silver Weed, has been used by tanners; and *P. reptans*, another English species, of which a pretty double-flowered variety is sometimes met with in gardens, was formerly employed as a febrifuge.

Potentilla Menziesii

The generic term, *Potentilla*, is derived by some authors from *potens*, powerful, or *potentia*, power, in allusion to the medicinal properties of the species; but as these are undoubtedly very weak, we incline to agree with those who consider the reference to be to the Latin diminutive, signifying little power.

The popular designation, *Cinquefoil*, alludes to the arrangement of the leaflets, which are often in fives, but by no means exclusively so; for many of the species, including *Menziesii*, have ternate foliage, and it is not rare to find on the same plants, leaves with segments varying from three to six in number; a few species have even pinnate leaves.—W. THOMPSON, *Ipswich.*

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

PRIMULA VERTICILLATA var. *SINENSIS*. *Nat. ord.*, Primulaceæ. *Linna.*, Pentandria Monogynia.—Native of Abyssinia. Flowers primrose-yellow. "*Primula verticillata* has been long cultivated in Europe, having been raised from seed brought, I believe, from the Sinaitic Peninsula; but the Abyssinian variety is of recent introduction into England by Messrs. Veitch. It flowered in the Royal Gardens in March of the present year; it grows freely on rockwork."—(*Bot. Mag.*, t. 6042.)

MENINIA TURBIDA. *Nat. ord.*, Acanthaceæ. *Linna.*, Diandria.—Native of Cochin-China. Flowers white, reticulated with pink nerves. It flowered at Kew in April. The plant is a powerful febrifuge, called *Thuong-son* by the natives.—(*Ibid.*, t. 6043.)

CRASSULA PROFUSA. *Nat. ord.*, Crassulaceæ. *Linna.*, Pentandria Monogynia.—Native of South Africa. Flowers white tinged with pink. "A free-flowering and remarkably ramous species of *Crassula*, sent from the Graaf Reinet district of the Cape Colony by Harry Bolus, Esq. The structure of the leaf is very curious. The margin, which is quite entire, is edged with a narrow band of chestnut-brown, within which is a series of orbicular, slightly convex, punctiform disks. These disks, when highly magnified, are found to consist of a very dense cellular tissue, that terminates downwards in a conical form, and communicates with the peripheral ends of the nerves, in the

loose parenchymatous substance of the leaf. The surface of the disk is studded with excessively minute stomata, of a different form from the other stomata on either surface of the leaf; the guard-cells of these stomata further contain on their outer edge a row of minute chlorophyll granules, giving them a most beautiful appearance. It was raised from seed received in 1871 from Mr. Bolus, and now forms a profusely flowering mass of branches and leaves, 2 feet in diameter; it flowered from March to June of the present year."—(*Ibid.*, t. 6014.)

RHODODENDRON MALAYANUM. *Nat. ord.*, Ericaceæ. *Linn.*, Decandria Monogynia.—Native of the Malayan Archipelago. Flowers crimson. "Dr. William Jack, of the late East India Company's service, a very able botanist and author of the 'Malayan Miscellanies,' was the first to make known this fine plant (in about 1823), which he discovered on the summit of Gunung Bunko, a remarkably insulated mountain, commonly called by Europeans the Sugar-loaf, in the interior of Bencoolen, Sumatra. Dr. Jack observes of this mountain that, though estimated at only 3000 feet in height, the character of its vegetation is decidedly alpine, a fact which he attributes to the form and consequent exposure of its sharp conical peak. *Rhododendron malayanum* has since been gathered repeatedly on Mount Ophir, Malacca, at an altitude of 1000 feet."—(*Ibid.*, t. 6045.)

BORONIA MEGASTIGMA. *Nat. ord.*, Rutaceæ. *Linn.*, Octandria Monogynia.—Native of south-west Australia. Flowers maroon-purple outside and pale yellow inside. "It was introduced into Kew by seed originally received from Baron von Mueller, and subsequently living plants were presented by M. Thozet. The somewhat aromatic fragrance of the flowers resembles nothing known to me; it is most delicious; and though not overpowering, soon fills a large room; and should it be capable of being obtained as a perfume, I may safely predict its being in great request. In these respects, of delicacy of odour accompanying a singular brown-purple colour, it resembles the *Tinnæa æthiopia* of Tropical Africa, and like the *Tinnæa*, the *Boronia* is very easy of cultivation, if treated like a Heath in an ordinary greenhouse."—(*Ibid.*, t. 6045.)

OPHALODES LUCILLE. *Nat. ord.*, Boraginaceæ. *Linn.*, Pentandria Monogynia.—Native of Asia Minor. Flowers some pink and others blue. "This beautiful plant has hitherto been found only in two localities, which are very distant from one another, in Asia Minor—namely, Mount Sypilus, near Manesis (the ancient Magnesia, north-east of Smyrna), where it was discovered by Ancher Eloi; and in the Eastern Taurus Mountains of Bulgar dagh, in the province of Cilicia (now Itschili), adjoining the Gulf of Scanderoon. In both places it inhabits considerable altitudes, attaining 8000 feet. It is decidedly the most beautiful species of the genus, and is well adapted for rockwork cultivation, remaining in flower for a considerable time in cool weather, and presenting all shades of colour in the corolla, from a pale pink-purple to azure. The specimen here figured was presented to the Royal Gardens by James Atkins, Esq., of Painswick, and which flowered profusely for a second time after arrival."—(*Ibid.*, t. 6017.)

ROSE—Mademoiselle Cécile Berthod.—"This pretty new Tea Rose is from the collection of Mr. W. Paul at Waltham Cross. The variety has been shown at some of the spring metropolitan exhibitions, and won a first-class certificate, being, as we think, very deservedly rewarded. The Rose is of good free habit, blooming abundantly, and the flowers are large and full, of a fine pure sulphur-yellow colour, the backs of the petals being almost white. Our collections of Tea Roses have received some very useful accessions during the last year or two, and amongst the novelties thus obtained we believe the variety now figured will be found to hold a foremost place, and will not disappoint those who cultivate it."—(*Florist and Pomologist*, 3 s., vi., 115.)

THE ROSE-SCENTED GERANIUM.—Some forty years since, or more, the "old Rose Geranium" was much prized, not for its flowers, for they are quite insignificant, but for the delicious fragrance of its foliage, which, like the Sweet Verbena (*Aloysia citriodora*) retains the scent when dried and kept in the pocket. My employer some three weeks since informed me that many years back he recollected, at Peper Harrow, the beautiful seat of Viscount Middleton, the then, as far as he knew, only remaining plant of that Geranium. I immediately wrote to Mr. Thompson, the gardener at Peper Harrow, and was happy to find that the old plant is still in existence, and Mr. Thompson

has been kind enough to send me some cuttings of it. It is well worth preserving.—G. H. COOKE, *The Gardens, Peniarth, Merioneth.*

VALUE OF FRUITS AND FLOWERS.

FRUITS and flowers have too often been considered only as the luxuries of life; but the more we use them, the more we are associated with them, the nearer shall we approach a refined and healthy temperament both of body and of mind. It is therefore our duty to develop these wonderful resources of nature, and to increase and improve them to their utmost extent. No employment is more consonant with the refinement and happiness of a rational being, none better calculated to develop the purest sentiments of our moral nature. "They are," said Mr. Webster, "a constant field where all sexes and ages, and every degree of taste and refinement, may find opportunity for gratification."—(*Extract from a Lecture by the Hon. Marshall P. Wilder to the Massachusetts Horticultural Society.*)

ROYAL HORTICULTURAL SOCIETY.

JULY 16TH AND 17TH.

On one of the finest days we have enjoyed this summer, but by no means hot, the Zonal Pelargonium Show opened, and it is to be continued this day. The flowering specimens are dazzling in their colours, and those whose memories stretch back to the old Tom Thumb would marvel indeed at the size both of pips and truss that is here to be found, not in one variety only, but in dozens. The Tricolors, on the other hand, which but a short time ago were all the rage, are dull, and present a great sameness. Notwithstanding the absence of exhibitors who had entered, but did not come forward, Mr. Eyles evoked at the last moment a very good arrangement in the conservatory corridors, where the Show is held, and by a more rigid adherence to time, in which respect the reins must be drawn tighter still, we believe it will be possible to have yet better effects in the future. Exhibitors entering a number of plants and then not coming forward at the last moment, render all preconceived plans futile.

Class I is for eighteen Zonal Pelargoniums in 6-inch pots, novelty and shape of flowers taking the precedence of size and training. Here Mr. George, gardener to Miss Nicholson, Putney Heath, is first with A. F. Barron, a fine scarlet, with a white eye; Edward Bennett, deeper in colour; Queen's Messenger, very large truss; La Grande Marque, fine truss; Lord Lonsborough, scarlet; Congress, fine orange scarlet; Circulator, free-flowering rosy scarlet; Lucretia, white, with pink eye; Polly King, salmon rose; and others all of his own raising. Second come Messrs. Bell & Thorpe with a collection not one of which is named except on tallies in the pots, but nearly all of them are beyond reach. The same remark applies to the third-prize lot from Dr. Denny, of Stoke Newington. Mr. Cannell, of Woolwich, also exhibits in this class.

In Class 2, for twelve Nosegays or hybrid Nosegays in 6-inch pots, novelty and shape of flowers again taking the precedence of size and training, Mr. George also takes the first position with a group, in which Grand Coup, bright rosy scarlet, is very fine. Mr. Cannell is second with a group in which Frank Miles, magenta crimson; Undine, deep scarlet; Mrs. Flyte, intense rose; Mrs. Turner, magenta rose; Mrs. F. Burnaby, pink, white at the base of the upper petals; and Matilda, are conspicuous. Third comes Mr. Goddard, of Twickenham. Messrs. Bell and Thorpe, Stratford-on-Avon, Mr. Turner, of Slough, Dr. Denny, and Mr. Rowe, The Rookery, Rochampton, also exhibit in this class.

For six specimen Zonal varieties Mr. Catlin, gardener to Mrs. Lermite, Finchley, is first with plants in splendid bloom, some of which measure 5 feet in diameter. The kinds are Monsieur Rendatler, Prince of Wales, Pioneer, Lord Derby (magnificent), Virgo Marie, and Leonidas.

In the nurserymen's class for six hybrid Nosegays, Messrs. Bell & Thorpe are first with an unnamed lot. For twelve double Zonals the same firm are also first with fine examples of Marie Lemoine, rose; Victor Lemoine and Charles Glym, scarlet; Mr. Gladstone, rose scarlet; and Siguet, together with Alba plena, a very poor white, and others. Second come Messrs. Wright, Lee, Kent. In the amateurs' class Mr. R. Watson, gardener to T. H. Bryant, Esq., Airlie Lodge, Surbiton, is first.

Golden Tricolors are exhibited in considerable force. The best eighteen come from Mr. Pestrige, Greenway Nursery, Uxbridge, and consist of finely-grown excellently-coloured plants of Prince of Wales, Mrs. Headley, Sophia Dumaresque, Mr. Rutter, Lady Cullura, Peter Grieve, Mrs. Turner, Florence, Salamander, Sir Robert Napier, Acme, Mrs. Dunnett, E. R.

Benyon, Vale of Evesham, Achievement, Sophia Cusack, Lucy Grieve, and Brilliant. Mr. H. B. Smith, Ealing Dean Nursery, is second with, among others, excellent plants of Jetty Lacy, Defiance, and Lady Cullum. The third prize goes to Mr. Wright, of Lee. For six Mr. Watson is first; Mr. Goddard, Twickenham, second; and Mr. Goddard, gardener to A. Chancellor, Esq., Richmond, third. In the class for the same number of Silver Tricolors the prizes go to Mr. Pestridge, Mr. H. B. Smith, and Mr. Wright. Among the plants shown are excellent specimens of Lass o' Gowrie, Miss Burlett Courts, Mrs. Roushy, Mrs. Col. Wilkinson, Italia Unita, and Silver Cloud. For four Mr. Beach, gardener to E. R. Pettie, Esq., Riverhead, Sevenoaks, takes the highest place; and the remaining prizes go to Mr. G. Goddard, Twickenham, and Mr. J. Goddard, Richmond.

Of the Golden Bronze Bicolors there is but a small exhibition. Mr. Pestridge is first for six in 8-inch pots with Black Douglas, W. R. Morris, Earl of Roslyn, Crown Prince, Reine Victoria, and Sybil, remarkably well grown but not in good colour. Second and third come Mr. Watson and Mr. Wright. The best group, however, is that from Mr. Beach, but these, having been grown in pots less than 8 inches in diameter, were disqualified; Mrs. John Lee, Countess of Kellie, and Earl of Rosslyn are very good.

In Class 13, for six Zonal varieties not in commerce, the prizes were offered by Mr. Cannell, of Woolwich. Mr. George is first with A. P. Barron and Edward Bennett, both of which received first-class certificates from the Floral Committee, and are very fine varieties; Mrs. J. George, very large truss, orange scarlet, fine form, first-class certificate; La Marque, and two others. Messrs. Bell & Thorpe are second, and take a first-class certificate for Czarina, white, tinged with rose at the eye.

In the next class, for six Nosegays or hybrid Nosegays not in commerce, the prizes are likewise offered by Mr. Cannell. Mr. George is first with Lustrous, fine dark scarlet (first-class certificate); Dr. Masters, magenta-flushed; Teresa, Beauty of Surrey, and The Shah, all large-trussed varieties.

For three plants of a new variety Mr. G. Smith is first with Santley, scarlet, white eye; Mr. George second with Mrs. J. George; and Mr. Smith, Edmonton, third. Mr. Turner sent three fine baskets of stage Pelargoniums, Protector, Ruth, and Giant.

For three plants of a new Nosegay or hybrid Nosegay Messrs. Bell & Thorpe are first with Happy Thought, with the centre of the leaves variegated with white, and having besides a dark zone surrounding the variegation, and the whole of the margin green, whilst the flowers are magenta crimson, but narrow-petaled. Mr. George shows Achievement, crimson scarlet; and Mr. Turner, Duchess of Marlborough, pink, white eye. For the best new Golden Tricolor, Mr. Pestridge is first with Mrs. H. Little, having a broad, clouded crimson band; Messrs. Bell and Thorpe are second, and Mr. Turner is third with Miss Morris. The best Silver Tricolor is Dolly Varden from Mr. Turner, the second best Mrs. J. Marshall from Mr. Pestridge, Uxbridge.

The best new Golden Self exhibited is Golden Banner, from Mr. Pestridge. The second prize was awarded to Messrs. Bell and Thorpe for Sulphureum, and the third to Mr. Turner for Golden Lover, a beautifully-coloured kind.

Mr. Pearson, of Chilwell, offered prizes for twelve distinct varieties of seedlings, not variegated, raised and sent out by him, in pots not to exceed 8 inches, the plants to be grown with as little training as possible. Mr. W. Brice, gardener to J. H. Lemitte, Esq., Knighton, Finchley, takes the first prize. His plants are in good health, the trusses very large, and the flowers splendid in colour. The most notable sorts are Bayard, Rev. C. P. Peach, Florence Durand, a very fine pink flower of the semi-Nosegay section, the flowers large, well-shaped, and the trusses remarkable; Amaranth is another fine pink flower, the colour very rich; Lord Belper, Lady Egerton, Thomas Speed, and Corsair. Mr. J. Catlin, gardener to Mrs. Lemitte, sen., East End, Finchley, comes second; Mrs. Vincent, Chumder Sen, and Mrs. Saunders, are fine.

For Dr. Demy's prize for a collection of plants, consisting of two plants of each of his seedlings that were sent out by Mr. William Paul in the spring of 1871, pots not to exceed 8 inches, plants to be grown with as little training as possible, Mr. J. Scott, gardener to Mrs. Howatt, Enfield, is first. The plants in this class were not to be subjected to much training, but the trusses were tied-out with sticks placed conspicuously in the pots. Wellington, Sir J. Moore, and Sir C. Napier are very fine. Messrs. Bell & Thorpe, Stratford-on-Avon, come in second with small plants.

For Mr. G. Smith and Mr. J. George's prizes for twelve varieties of Pelargoniums, raised by Mr. J. George, to be shown in pots not exceeding 6 inches, quality of flower to be the primary test of merit, Mr. E. Rowe, The Rookery, Roehampton, is first. In this class the plants are necessarily small, but Mr. Rowe's plants are very neat, and the trusses good. Circulator, Dr. Livingstone, King of the Forest, and Master Harry are fine. Mr. G. Goddard, Twickenham, is second with nice plants; and Messrs. Carter & Co., of High Holborn, have a collection.

Prizes were offered for *Disa grandiflora*, but no one came forward to claim them.

Of six *Liliums* in pots, nurserymen, Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, has the best, and Mr. C. Turner, of Slough, is second. Mr. Ware has *L. auratum*, *L. longiflorum*, *L. croceum*, *L. excelsum*, &c. Mr. Turner's are principally *L. auratum*.

The successful exhibitors of Delphiniums, Pentstemons, and hardy perennials are Mr. Ware, of Tottenham, Mr. Porter, Isleworth, and Mr. Parker, of Tooting; the latter, in particular, contributes a very fine group. In Carnations and Proteas all the prizes go to Mr. Turner, of Slough, Mr. Norman, and Mr. Pizzey, Mr. Turner's blooms being remarkable for their beauty; but we have not time just now to do more than render a well-deserved meed of praise to the exhibitors of these old favourites.

The prize for the best collection of Lettuces was awarded to Mr. Osman, of the South Metropolitan Schools, Sutton, who has large examples of numerous Cos and Cabbage kinds.

Among miscellaneous subjects, which are less numerous than usual, we must mention a fine group of the beautiful crimson *Spiraea palmata* from Mr. C. Noble, of the Sunningdale Nurseries; a fine lot of Balsams from Mr. Smith, of Ealing Dean; a good mixed group from Mr. Aldous, South Kensington; and a remarkably fine collection, both of Tricolor-leaved and flowering Zonal Pelargoniums, from Mr. W. Paul, of Waltham Cross. In this genus, rose, edged with white, and Marathon, Nosegay, brilliant crimson flushed with magenta and orange, received first-class certificates. Mr. Keynes, of Salisbury, had a cultural commendation for boxes of new Roses of 1872, in which President Thiers, Etienne Levet, Anguste Rigotard, and Princess Beatrice were conspicuous.

FRUIT COMMITTEE.—Alfred Smee, Esq., F.R.S., in the chair. Mr. Harris, gardener to Mrs. J. H. Vivian, Singleton, Swansea, sent three very handsome Queen Pines, one of which weighed 6½ lbs., and was a remarkable specimen. They were awarded a cultural commendation. Mr. G. Westland, The Gardens, Witley Court, sent four Queen Pines, weighing in the aggregate 22 lbs. They were awarded a cultural commendation, but they were not equal to those shown by Mr. Harris. Mr. G. Ward, gardener to T. N. Miller, Esq., Bishop Stortford, sent two fruit of Moscow Queen, under the name of "Queen." Mr. T. Farrow, gardener to T. Batters, Esq., Enfield, sent a seedling Grape, called Golden Drop, raised between the Black Hamburgh and Canon Hall. It was not considered of sufficient merit to receive a certificate. Messrs. Standish & Co., Ascot, exhibited two bunches of Ascot Citronelle Grape, which received a first-class certificate last year. The flavour was a fine brisk Muscat-Citron flavour. A letter of thanks was awarded. R. B. Postans, Esq., of Brentwood, sent a collection of nine sorts of seedling Strawberries:—Boz, a medium-sized fruit, similar in shape to La Constante, was passed; Dr. Lindley was also passed; Chancellor was also passed; Princess was a large variety, but not of good flavour; Pomona was of superior flavour to the preceding, and the Committee requested to see it again; Nabob is a large handsome variety, but the flavour inferior; Sylvanus is also a large variety, and the flavour inferior; Excelsior is a large handsome variety, and, as it was not quite ripe, was asked for again; Exquisite is large and well coloured, and the flavour good; it was asked for again. These were fine handsome-looking varieties, but the recent heavy rains had diluted the flavour. Mr. William Paul, of Waltham Cross, sent a seedling Strawberry of medium size, very firm and compact, with a red flesh throughout, and with a fine Pine flavour. The opinion was that it was a good Strawberry, but too small. Mr. T. Stevens, gardener, Wray Park, Reigate, sent a seedling Melon, which was passed. Mr. Johnston, The Gardens, Glamis Castle, N.B., also sent a seedling Melon, which was passed. Mr. Bennett, The Gardens, Hatfield, sent sprays of Peaches and Nectarines laden with fruit, to show the abundance of the crop on concrete wire walls. Mr. P. Dancer, of Little Sutton, Turnham Green, sent sprays of Monarch Gooseberry completely studded with fruit, showing its wonderful prolificacy. Mr. W. Child, The Gardens, Pool Bank, Birkenhead, sent a seedling Melon of good but not remarkable flavour. Mr. D. Piccirillo, Wigmore Street, sent three very large Flat Red Tripoli Onion, grown at Naples, which were of enormous size.

FLORAL COMMITTEE.—W. B. Kellock, Esq., in the chair. The subjects submitted to the Committee on this occasion were but few. Of new Roses, Messrs. Paul & Son, Cheshunt, exhibited S. Reynolds Hole, dark maroon scarlet, fine form, and received a first-class certificate. A like award was made to T. Laxton, Esq., Stamford, for Empress of India, another dark variety of fine form. Mr. J. Walker, Thame, likewise received a first-class certificate for Beauty of Thame. Mr. H. B. Smith, Ealing Dean, sent Golden Tricolor Cesareva with finely-coloured leaves. A first-class certificate was awarded to Mr. J. Cocker, nurseryman, Aberdeen, for Phlox Miss Robertson, a fine white variety. Mr. J. Gee had a certificate for Gloxinia Grand

Monarch, large, erect-flowering, purple; Messrs. Cripps & Son for hybrid Clematises Guiding Star, violet purple, with a purplish crimson band, and for Louis Van Houtte, rich violet-blue, quite novel in colour. Azara microphylla, a hardy ornamental shrub from Chili, shown by Messrs. Veitch, of Chelsea, had also a first-class certificate.

From Messrs. Barr & Sugden, Covent Garden, came a basket of Lillies, Ixias, and other bulbous flowers. Mr. Ware sent a large collection of hardy plants, of which *Acantholimon venustum* was awarded a first-class certificate; Messrs. Carter & Co. one of double and single-flowered Zonal Pelargoniums, together with Lobelias, of which Charity—purplish pink with a white eye—had a first-class certificate, also *Clarkia integrifolia limbata*, purple edged with white, very pretty. Mr. Norman sent a number of new Carnations and Picotees.

From Messrs. Bell & Thorpe came Zonal Pelargonium Mrs. Carr, with double rose-coloured flowers, and leaves variegated with creamy white: this received a first-class certificate, as did also Pelargonium Princess from Mr. W. Paul, and Lustrous from Mr. George. Mr. Bull had also a first-class certificate for *Dipladenia Barclayana*, with splendid deep-coloured flowers; and Mr. Kimpton one for *Coleus Mrs. Knatchbull Hugessen*, cream-coloured.

FLOWER-SHADE.

SEEING an article in your No. 640 on shades and shelters, in which your correspondent talks of "home-span shades," brought to my recollection a flower-shade used by a great florist near Dublin for shading Tulips and Carnations, which, to my mind, is as cheap and efficient as anything can be, and also easily made. I therefore send you a description of it. It is made of any old pieces of oilcloth, such as is put down in halls, &c., which may be knocking about a house, and are generally looked upon as rubbish, and either thrown away or consigned to the lumber-room. A circular piece of any dia-

Fig. 1.

Fig. 2.

Fig. 3.

meter required is cut out, as in *fig. 1*; from this a triangular piece is cut out, as shown by the dotted lines; the two edges are then overlapped, and a couple of nails driven through and clenched inside complete the shade (*fig. 2*). The apex of the cone is then cut off, which leaves a small round hole in the centre of the cap. When a Carnation is in flower a small hole is drilled in the stick, to which the plant is tied at the required height, a nail (brad) passed through, and the cap slid down the stick until stopped by the nail; a small wedge is inserted in the hole between the stick and cover, and the whole is firm (see *fig. 3*).

This, I think you will say, is as cheap and easy to make as the painted canvas shade, and would stand more knocking about and last longer too. —F. T. B.

THE SHAH OF PERSIA.—We are informed that Messrs. James Carter & Co. attended at Buckingham Palace to receive His Majesty's commands for a considerable supply of seeds of all

kinds. We are very glad that the Shah is an encourager of the culture of the soil. Persia vastly needs improvement in this. A Scotchman said the country's soil is of two kinds—sand mixed with salt, and sand without salt.

THE BEAUTIFUL AND USEFUL INSECTS OF OUR GARDENS.—No. 6.

THE number of insects killed by mere accident is pretty considerable, and, if there existed an accidental death insurance company among these six-legged individuals, I suspect the rate of premium would need to be rather high! Man, too, is destructive to insect life without as well as with intention, though he has but two legs against an insect's six, and many of these creatures possess wings as an additional means of locomotion. Some species seem to have a fatality for blundering along, so as to get upon pathways or expose themselves to the perils of fire and water; and despite their tough wing-cases, the human foot puts an end to the existence of various beetles, as was noticed long ago by Shakspeare. As I narrowly avoided treading upon a newly-emerged cockchafer recently (for this occasional foe to the gardener seems to be coming out rather briskly this year), I recalled with some amusement the different meanings which have been drawn out of the observation, perhaps hastily penned, that

"The poor beetle that we tread upon,
In corporal sufferance finds a pang as great
As when a giant dies."

The two extremes of the deductions drawn from this are: one, that in reality giants do not feel any more than beetles, only imagination leads them to think they do; and the other, that beetles have as acute sensibilities as men, therefore we should be chary of taking their lives or inflicting injuries upon them. The ordinary human individual, however, regards these insects with disgust sometimes amounting to alarm, and does not at all hesitate to terminate their lives with or without provocation so to do. I believe the gardener for the most part is neither excited to indignation nor admiration by the name "beetle," except it may have happened that the too-well-known black beetle—no beetle really—has paid him an unfriendly visit.

There are some beetles injurious to our gardens in their larval stage, and some, again, as perfect beetles; yet only here and there are these recognised by the horticulturist and their true character known. They are most usually grouped under the indefinite terms of "the flea," "the fly," or "the grub." True it is that the non-scientific man might with justice assert that the scientific giver or collator of names is at times unacquainted with the habits of the insects he examines, and very much at a loss to suggest a remedy when they are injuriously abundant; yet he who devotes his time to the driest of technicalities connected with entomology may still do the horticulturist good service, and also the general naturalist, for what is many an observation worth unaccompanied by the means of identifying the species to which it attaches? This may be deemed to be a little beside our subject, but there is still at times an unfriendliness showing itself between those who ought to be at one, since they are students, though in a different way, of the same branch of natural history. We cannot expect to find many Admirable Crichtons in entomology, who shall be learned alike in anatomy, classification, habits, and geographical distribution.

"Returning to our mutton," or rather to our beetle-flesh, not to that of sheep: it should be stated that we have a goodly number of beetles which are of decided utility in our gardens and orchards, and their services form a set-off against the undeniable injuries done to us by other species. We see, I believe, much less of our beetle-friends (excepting the universal lady-birds), than of our foes, and hence are scarcely aware how much we are indebted to them. Besides those which are predatory in their habits, hosts of beetles act as scavengers, being engaged in destroying or decomposing matters which are thereafter salutary to the ground instead of remaining noxious to the atmosphere, as they would be if undisturbed. In this particular work the Staphylinide are largely engaged, and they may often be detected under leaves putrescent or decaying; though the beetles of this family are indeed well-nigh omnivorous in habit and active enough at night, but frequently apt to conceal themselves in the daytime. Many Staphylinide are carnivorous in the larval as well as in the imago condition, and it is hinted they feel no compunction in devouring a juvenile relative.

Under the popular name of "Cock-tail Beetles" several Staphylinide are included, and the most familiar of these is

that represented in the accompanying figure called *S. (Goërius) olens*; and it can certainly be very odorous if annoyed, being furnished with an apparatus by which is given forth an offensive liquid. Sometimes it will also exude an acrid fluid from the mouth, apparently of a similar nature. This and other species allied have also been designated Rove Beetles from their propensities, and the common species specially has attached to it the epithet of the "Devil's Coach-horse." A modern naturalist justifies the appellation, for he says that he made a "coloured drawing of the head of this insect, representing it with its jaws widely opened as if in the act of seizing its prey, and the light glancing from its polished eyes. It was a perfectly faithful sketch, drawn by the help of the camera lucida, but yet almost

Wood points out, the beetle is at times baffled by the earth worm's practice of dragging down leaves to some depth into the openings it has made—a practice which has been accounted for in a variety of ways. These leaves are just as likely to be those of living plants as not, and hence one decided objection the horticulturist has to a multitude of these creatures in his domain. But these leaves impede the progress of *O. olens* in pursuit of worms, though perhaps the insect would be more determined in the chase were it not capable of feeding on so great a variety of substances living and dead.

The larva of *O. olens* is, of course, devoid of wings, yet quite as capable of providing for itself as when fully matured. It is predacious even when quite young, and, though darkling in its habits, comes into view sometimes, and may frequently be detected under stones and logs. How it wriggles into some of the situations where we find it is surprising. Many of the small insects and other creatures killed by this larva are not actually eaten up; the juices having been extracted, the larva often quits its prey and renews its search for more. The pupa is quiescent and usually concealed under the earth, contrasting strangely with the restless larva and imago.

The Tiger Beetles claim a passing notice, as at least occasionally certain of the common species are to be found on the wing in gardens situate near waste or heathy land; and even when flying or running in other spots, they kill insects which are at times frequenters of gardens, though bred elsewhere. The familiar *Cicindela campestris* is a good representative of the tribe; it is an insect wonderfully active, though it takes but short flights for the most part. Decidedly different in appearance from the species under our notice just now, with a rather elegant outline, and displaying pleasing colours, it is quite as ferocious as the repulsive *Staphylini*. At its front it bears a deadly weapon, resembling in miniature two sickles crossed at the points, and poor are the chances of any insect that has the misfortune to come in the way of these. For its own security, and to assist it in its pre-

dacious excursions, the Tiger Beetle has eyes so situated that an object approaching from any direction is at once seen. Like wasps and others of the Hymenopterous order, the *Cicindelidæ* rarely devour their victim; partially dismembering it, they remove the soft contents of the body. An alarm will make them fly off with anything they are grasping, but they have not strength of wing to carry it far. A specimen of *Cicindela campestris* held between the fingers leaves an odour which has been compared to that of a crushed Verbena leaf: it is not disagreeable. In some species of *Cicindela* we notice a perfume resembling that of the Rose or Sweet Briar.

The larva of this species cannot emulate the rapid movements of the imago. It has short legs and a body not adapted for locomotion. But what it cannot secure by force it obtains

Oecypus olens.

everyone who saw it for the first time thought that it was a fancy sketch for an imp." With regard to the pugnacity and courage of the insect, the same author observes that when he was out with a party of friends a cock-tail beetle brought the group to a standstill. The ladies shrank back, but the naturalist advanced stick in hand. "I kept the creature fighting me for about ten minutes, its determined attacks and the fierce looks which it put on exciting general applause. Even when at last I allowed it to retreat, I had only to strike the end of my stick on the disputed ground to provoke another attack." The rights of the quarrel were evidently not on the side of the naturalist, but on that of the beetle. The bite of this species and of other *Staphylinidæ* should be avoided, however, as it has been known to inflame the skin considerably.

The menacing aspect of *Oecypus olens* is, as Kirby remarks, increased by the mode in which, scorpion-like, it turns up the abdomen, as if about to strike its foe. This is, however, only a threat, and the flexible abdomen subserves other purposes in the insect's life. The observer who is no entomologist can see at a glance that the wings are of good size, and the elytra or wing-cases are small. In many beetles the latter are of service in folding-up the organs of flight, but in *O. olens* the delicate membranes could not be packed away without other assistance, which is afforded by the hind segments. After an excursion in the air (should one of these beetles be noticed in the act of coming to rest), a cock-tail beetle gives its wings a flourish, and then by the help of the tail puts them under the elytra, and is all ready for a run. The operation is performed with great rapidity.

Besides destroying insects, this common beetle helps to reduce the number of earth worms in the garden. It does not find any difficulty in pursuing the slippery annelid, since its long body and powerful structure enable it to follow its prey along the tracks beneath the ground, though, as the Rev. J. G.

Cicindela campestris.

Ambush of larva of *Cicindela campestris*.

Larva of *Cicindela campestris*.

For this and the other illustrations to the present article we are indebted to Figuer's "Insect World," published by Messrs. Cassell.

by stratagem. In sandy ground we may expect to find the ingenious pitfalls constructed by this larva, which suggest to us the oft-described traps made by the ant-lion, not a native of these islands. The pit sunk by the larva of *Cicindela cam-*

pestris is more rude, though going to some depth; and the immature Tiger awaits its prey, usually near the opening, wedging itself there by means of hooklets, with which it is furnished for this very purpose. Having seized some by-passer, the larva drops with it to the bottom of the pit. The digging-out of this is accomplished by the legs and horny head; and

the insect has a natural hod, in the form of a hump, upon which it rests the sand or earth as scooped out, and ejects it near the mouth of the pit, not often troubling itself to remove the rubbish to any distance. The change to a pupa takes place within the same burrow, the mouth being then carefully closed. Here the insect remains from autumn until spring.—J. R. S. C.

ORTHOSIPHON STAMINEUS.

This is a very pretty and interesting member of the Labiata, and is well deserving of the attention of growers of stove plants; for, coming into full bloom about the end of July, it becomes extremely valuable in a decorative point of view,

servicing to enliven the plant stove just at the time when there is somewhat of a dearth. As a genus, *Orthosiphon* is closely allied to *Ocymum*, *Coleus*, and *Plectranthus*, but its inflorescence reminds one of a *Clerodendron*.

Orthosiphon stamineus.

Orthosiphon stamineus is herbaceous in habit, and forms neat little bushes, which if required may be had in bloom when only about 6 inches high. Most cultivators will, however, prefer growing it to a larger size before allowing it to flower, and, therefore, when any bloom buds which are not required to develop make their appearance, they must be picked off. The stems and branches of this elegant little plant are furnished with light purple hairs; leaves sharply oval, toothed on the edges, and dark green on the upper side, but glaucous beneath, the veins in addition being sparingly clothed with short white hairs. The flowers are produced in terminal racemes, as the illustration kindly lent us by Messrs. James Veitch & Sons, will show, although it fails to convey an adequate idea of the plant's beauty. The corolla is about an inch in length, bluish-lilac in colour, having the stamens much exerted, which adds materially to the beauty of the raceme.

The culture of *Orthosiphon stamineus* is really of the simplest nature, which is another feature in its favour, inasmuch as any amateur possessing a cool stove may take it in hand without the slightest risk or fear of failure. Drain the pots well; for soil use about equal parts of peat, loam, and good leaf mould, adding a little sharp river or silver sand to the

whole so as to make it feel gritty when taken in the hand, and during the growing and flowering season supply the plant liberally with water. It appears to be widely distributed over India and through the islands of the Indian Archipelago, but was introduced to our collections from the neighbourhood of Cape York in north-east Australia, by the late Mr. J. G. Veitch. —EXPERTO CREDE.

ESCALLONIA MACRANTHA.—I can with much pleasure endorse every word Mr. Robson has said with respect to the beauties of the above plant. I have one planted in the south-east corner of a sunk-fence brick wall about 6 feet high, which is at the present time one complete mass of bloom, borne upon the young wood of last season's growth in sprays from 12 to 18 inches long. It has almost assumed the character of a shrub, as it has been nailed in very little; so the growth it makes during the summer is left to ramble as it likes, which is probably the cause of its blooming so profusely. The young growth it is now making above the top of the sunk fence will again flower late in the autumn, but not so profusely as it does in the summer. It is planted in a rich stiff loam, which appears to suit it in every way, as it makes shoots from 18 inches

to 2 feet long, with rich shining green foliage as large as that of the Laurel.—W. MCP., *Ashbourne, Derbyshire.*

PLANTING-OUT FORCED STRAWBERRIES FOR A MAIN CROP.

For the last nine years we have planted out our forced Strawberry plants in a systematic way, for a main crop of fruit, and have never in one instance failed in securing a most abundant crop. I am aware it is a common practice to plant-out forced plants as a kind of auxiliary crop, most dependance being placed upon the permanent plantations; but where Strawberries are forced in any quantity I would advise the planting of them out in a regular way for a supply of fruit for preserving and other purposes. Such plants bear excessively the first year, and never fail. The second year they will bear a heavy crop again, but after this they should be trenched down. Besides, the plants are soon enough if they are planted out in August. We follow our second early Potatoes with the Strawberries, and have been as late as September in finishing, but the last-planted plants bore just as well as the first in the following season.

Our practice is to put the plants out in a sheltered corner as they have done bearing: if the pots are wanted, the plants are turned out and the balls packed closely together, filling up the crevices with a little fine soil, and in this way they are left till they can be planted out, not forgetting, in the meantime, to water them abundantly. If the ground has been manured heavily for the Potatoes, it is just dug over and the Strawberries planted at the same time, 18 inches apart between the plants, and 2 feet between the rows. This is ample, for forced plants do not make such growth as permanent ones: neither do they root deeply, for which reason they are somewhat apt to suffer from drought; but a thick mulching of half-rotted stable litter put on early in spring prevents any risk of this kind, and works little less than a miracle in swelling-off the fruit and promoting the general health of the plants. We have often gathered more than 1 cwt. of Black Prince from a piece of ground of less than half the extent that permanent plants would require to produce the same, for we plant this variety (forced plants) 1 foot apart between the plants, and 18 inches between the rows. Last year we began planting about the middle of August, and the plants are now perfectly smothered with bloom, and the forced plants of 1871 are but little behind them.

I ought to state that when the plants are put out, the old leaves which have been developed in the forcing-house should be shorn clean off, and the balls should be buried as deeply as is possible without burying the crowns altogether. Plants of which the surface-roots are left exposed to the air never do so well.—J. SIMPSON (in *The Gardener*.)

NOTES AND GLEANINGS.

It has lately become the fashion to visit the sins and delinquencies of the ROYAL HORTICULTURAL SOCIETY on the head of the SUPERINTENDENT OF SHOWS. Because a good deal went wrong, and some people were dissatisfied, at Bath, it has all been laid to the charge of the Superintendent. Now, although we do not regard the Superintendent as infallible, we do say that, so far as regards the breakdown at the Bath Show, he is no more to be held responsible for them than Tenterden steeple is for the present condition of the Goodwin Sands. Has it ever occurred to the minds of fault-finders what it is to have the responsibility of such a show, with all its conflicting interests and ramifications, at a time when the Society was all "sixes and sevens," with an inexperienced Council and Secretary, and with limited powers placed in the hands of the Superintendent? It is easy to find fault when the facts are unknown. Mr. Eyles can no more make bricks without straw than other men can; and when those who enter collections of plants for exhibition do not send them, nor give timely intimation of their intention not to send them, it cannot be wondered at that the "big tent" should look thin, and that the grouping and disposition of the plants which had been decided upon days before should have to be hastily reconsidered at the eleventh hour, when there are fifty other things to be attended to. If exhibitors make application on Monday morning to be permitted to alter their entries, and if they crowd the office and harass the clerks for their cards all the forenoon, when the judging ought to have commenced, it is

hard that any individual person should be made responsible for the shortcomings consequent upon such conduct.

Until the Council take the matter in hand, and lay down irrevocable rules which all must adhere to, and the whole thing is properly organised under their authority, we fail to see how any person can be expected to be held responsible for the failures which have taken place. Hitherto there has been no direct action of the Council, and the Superintendent has not had a staff given him adequate for carrying out such an undertaking successfully. There has been far too much cast upon his shoulders, and we trust that in future, if the shows are to pass off successfully, a properly-organised staff distributed over the various departments, and under the direction of a competent head, will be appointed. It has always been a marvel to us how any single individual could possibly direct the varied details of such an exhibition.

— THE POST OF ASSISTANT SECRETARY TO THE ROYAL HORTICULTURAL SOCIETY, vacant by the resignation of Mr. Richards, is succeeded to by J. S. Davenport, Esq., who has been elected out of 395 candidates.

— A VERY handsome plant for a single specimen on a lawn is FERULA TINGITANA, its large, deeply-cut, feathery-looking foliage and large yellow flowers producing a fine effect in such a situation.

— MR. W. CARRUTHERS has just issued his official report for 1872, of THE DEPARTMENT OF BOTANY IN THE BRITISH MUSEUM. The additions to the herbarium during the year are spoken of as large and important, rendering more and more pressing the necessity of increasing accommodation for the arranged herbaria. The species included under several of the natural orders, both in the general and in the British herbarium, have been entirely re-arranged during the year; and much use has been made of the herbarium by botanists preparing monographs for a number of different publications. Numerous interesting additions have also been made to the structural series, both in the fruit, the fossil, and the general collection.—(*Nature*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

At the time of planting Celery, Endive, or any other culinary vegetable, they should by no means be deprived of any portion of their leaves. This practice is still continued by some persons, but it is evidently a bad one, and may be proved as such by trying both methods. In planting, great care should be taken to press the soil close to the roots. Plant out some of last month's sown Cabbage for use in the autumn as Coleworts; make a sowing about the end of the week for the first main spring crop. The Capsicum plants should be kept watered during dry weather; if a little litter be laid round them they will not require water so often. There is a frequent complaint of their not fruiting sufficiently early to ripen; I know not how it can be expected when the plants receive no attention whatever, and consequently do not begin to grow till the autumnal rains set in. Thin the late-sown crops of Carrots; loosen the earth between them where they have been sown in drills. The earliest-planted Celery will now require to be gone over and be divested of the small lower leaves and side shoots. The trenches should afterwards be thoroughly soaked with water previous to the plants being earthed-up, which should be done the following day as soon as they are quite dry. As the Cucumber plants on the ridges spread, cover the soil with short grass; this will keep the earth moist and the fruit clean. Transplant a few more Endives, and make another sowing; a few days' difference in transplanting at this season sometimes proves of great advantage. A last sowing of Dwarf Kidney Beans should now be made in a sheltered situation; the drills should be watered if the soil is very dry. *Hyoscyamus* for drying or distilling should be cut before the flowers expand, as they afterwards lose those qualities for which they are most valued. *Sorrel* should be cut down if required for use in the autumn.

FRUIT GARDEN.

Proceed with the thinning of Peach-tree shoots where they are too thick, taking off the laterals, and exposing to the action of sun and air all the wood you mean to retain for next season. On old trees of Cherries and Plums lay-in a succession of young wood in all parts of the tree, which, being kept close to the wall, will in a few years furnish finer fruit, and produce more plentifully than old unsightly spurs will do. Shorten the side shoots of Gooseberries and Currants, if this has not been already done; on plants previously shortened, the points of the leading shoots may now be taken off with advantage. Keep the late sorts of Strawberries, such as the Elton, well mulched with grass or straw to keep the fruit clean. Look after the runners of Keens' Seedling and other early sorts. Where time and labour are not

overtaxed, it is a good plan to layer each runner in a pot, and to cut it from the parent plant when the pot is full of roots; or rich compost may be strewed between the rows to encourage the rooting of the runners. The method generally adopted is to choose a situation with a good aspect, dig it finely, supply it with a good dressing of old Mushroom dung or other manure; cut off the runners as soon as they have made two or three leaves and are beginning to protrude roots; prick them out on the prepared ground 3 or 4 inches apart; shade until they begin to grow, and lift with balls of soil for forcing or making fresh plantations as wanted. The advantage of this system is that you can clear away all the runners and the superabundant plants almost as soon as a plantation has finished bearing, thus affording free exposure to those buds which you expect to bear fruit next season.

FLOWER GARDEN.

Flower gardens are at last becoming a little cheerful, and the plants are making-up for the time lost in the spring. Look over the beds of Scarlet Pelargoniums, and stop the leading branches wherever a flower bud is perceptible. This will tend to keep the plants dwarf, and the flower buds will be much increased in size by the concentration of sap. Beds of Petunias and tall-growing Verbenas are generally much disfigured by being broken about in the stormy weather. To avoid this, provide some strong pieces of birch branches and place them in the bed, so that after they are covered they will support the branches and prevent their being blown about. Attend assiduously to the removal of all decaying flowers, especially on profuse-flowering Verbenas; this will tend to prolong the season of growth and bloom. Roll, mow, and sweep the grass and walks at least once a-week. Prepare a temporary pit in the reserve garden, either by building turf walls, or excavating the earth a few inches deep, and forming an embankment round the sides, for the propagation of Scarlet and other Pelargoniums, indeed for all free-striking plants. This pit may be covered with Whitened or oiled canvas, and if there be 3 or 4 inches of light sandy soil for the cuttings to strike root into it will answer admirably. Heartsease, Penstemon, and most plants which make branches near the surface of the ground, may be readily increased by placing some light sandy soil about the young shoots, into which they will strike root, and then may be removed into nursery beds.

GREENHOUSE AND CONSERVATORY.

Some of the stove plants that have recently been brought into the conservatory will require attention to prevent their being injured by damp during cloudy weather, and it will probably be necessary to use fire heat occasionally for the purpose of drying the atmosphere of the house. The propriety of this will largely depend upon circumstances, for in small well-ventilated houses damp will hardly be troublesome; whereas in lofty houses with but little ventilation, and the roofs overgrown with climbers, it may be very troublesome. But at this season there is nothing to fear from cold, and air should be freely admitted on every favourable opportunity, using every care to keep the atmosphere of the house as dry as possible, and keeping the plants clear of decaying flowers, &c. Considerable care will also be necessary in watering recently potted specimens, whether of the soft-wooded or hardwooded class, as in the present state of the weather they will require little water, and will be speedily injured by a careless supply. Continue to carefully regulate the growth of climbers, but avoid tying them too closely, and allow them to grow according to their natural habits as much as circumstances will admit. Examine the border plants frequently for insects, which, if allowed their own way at this season, soon injure the young tender growth. The *Lunulias* are matches; subjects for the conservatory borders and are deserving of every attention, but they are very subject to black thrips, and if this pest is in the house it will soon disfigure their noble foliage unless kept under by some means. Tobacco smoke is the most effectual remedy for this pest, and repeated washings with the engine the next best; but there must be no trifling with this enemy, otherwise the beauty of the plants will be sacrificed for the season.

PITS AND FRAMES.

These structures are now partly stocked with plants which are coming forward for another season. Prepare a slight hotbed for a frame, and begin to increase such plants as you require a large stock of next season. Mangles and other variegated Geraniums are generally tardy strikers if left till late in the season, therefore begin in time.—W. KEWE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

In this department, except in hoeing the ground to destroy weeds, little has been done but gathering small fruit for preserving. It is abundant this year, and is being gathered in excellent condition. Raspberries we have never had in such abundance. Fastolf and Carter's Prolific we think the best bearers.

Strawberries in our light soil require to be planted every year, and with plenty of manure added to the ground they yield abundantly. Black Prince and Kears' Seedling are the sorts most esteemed in the kitchen. We have grown more varieties this year than we ever did before. Late Prince of Wales, kindly sent by Mr. Record, is worthless as regards flavour, and not for a moment to be compared to Frogmore Late Pine or La Constante, nor does it bear more freely than those two excellent varieties.

Peas.—We made a rather large sowing on the 9th. The ground is well prepared, and we sowed both early and late sorts on trial. We had equal quantities of Laxton's Alpha, Taber's Perfection, and Kentish Invicta. We shall continue to grow the first two sorts, but Invicta must give place to that finest of all early Peas for exhibition, William I. Although I mention it as being valuable as an exhibition sort, it is equally valuable for kitchen purposes. The dried seeds are blue, and the plant is in the way of Invicta more than Alpha. A succession crop of Peas just forming pods has been attacked by thrips. Can any correspondent suggest an easily-applied remedy for the destruction of this pest on the Pea? After dry weather sets in, we find much difficulty, owing to the thrips, in obtaining crops from this most useful of all vegetables to us.

FRUIT AND FORCING HOUSES.

Pines.—We have some strong suckers on the Queen and Charlotte Rothschild Pines; these we shall pot at once, and place them in the house from which succession plants have been removed. They are potted in 6, 7, or 8-inch pots, according to the size of the suckers; from these pots they will be shifted at once into the fruiting-pots. We do not wish to have a quantity of fruit at a time, as with the limited means at our disposal, it is not possible to secure a constant supply; but we manage to do the next best to this, and that is, instead of having a glut at one time and no more for weeks, or even months, we produce a continuous supply, only one or two fruits ripening at a time, and by a little forcing or retarding we have a fruit or fruits at the time required. We plunge the newly-potted suckers at once into a bed of fermenting material, and if the bottom heat is 100 or 110 the formation of roots will take place more quickly. It is not safe to plunge them in such a strong heat after the roots have reached the sides of the pots, as the young rootlets would in all probability be injured. We give air freely night and day when fruit is ripening, and maintain a rather dry atmosphere in the house.

Vines.—In the earliest vineyard all the Grapes have been cut, and, as soon as they were cleared off, the Vines had a thorough drenching with a garden engine; the water was thrown with some force against the under sides of the leaves to cleanse them effectually from red spider. We read of a clever gardener, one that grew Grapes well, who, when he fancied the growth on his Vines was over-luxuriant, instead of cleansing the leaves from this pest, allowed it to increase in order to check the over-luxuriance. We do not fancy the red spider about our houses anywhere, nor do we give it any rest until it is destroyed. We also with strong force send the water into corners and crevices of the walls to wash out spiders, &c. These are also troublesome in a vineyard. One will sometimes establish itself in the centre of a compact bunch and spin its web amongst the berries. It is very difficult to dislodge them from this position, but a slender piece of wood thrust amongst the berries where the insect is concealed will accomplish it. As the wood is well ripened, all the ventilators are kept open night and day. In the late houses the Grapes are showing signs of colouring, the necessary treatment being plenty of ventilation with less moisture in the house. The lateral growths do not now require stopping so often, but they must be gone over occasionally. There is one thing we would notice here: A man should not go into a vineyard to thin Grapes, pinch off laterals, or perform any other work amongst Vines, if he has been working in houses or amongst plants infested with red spider. Young men are sometimes careless in a matter of this kind, and the hint may be useful.

Orchard House.—We continue to surface-dress all pot fruit trees that require it, using a rich compost of horse droppings and loam in equal proportions, thrown together in a heap until it ferments. All the trees are bearing good crops of fruit and growing freely. In dry hot weather they are freely syringed, and watered at the roots twice daily, but only clear water is used. We have given them manure water, but this caused many of the leaves to become spotted and to fall off. That the manure water was the cause of this there was no doubt, as on discontinuing its use the plants regained health and vigour. Plum trees had become much infested by aphides, and the Peach and Nectarine trees were not free from them. Syringing is of no avail, but a thorough fumigation with tobacco soon cleared the trees.

CONSERVATORY AND PLANT STOVE.

Azaleas are making their wood, and require daily syringing and the house to be shut up at four in the afternoon. We used to place the plants in a pit by themselves, but now they are too large. This necessitates the shutting-up of the greenhouse

earlier, and the rather moist atmosphere does not suit the flowers; but as plenty are to be had out of doors, it does not so much matter.

The stage *Pelargoniums* have been turned out of doors, and they are cut over according to the time they are required to be in flower. We have plenty of plants coming into flower which will keep up a succession in-doors. Although they are plentiful outside, it is not possible to cut them good enough for button-hole and other bouquets, or for furnishing the vases. Double Zonal *Pelargoniums* are valuable for many purposes, especially such sorts as Madame and Marie Lemoine. These we have in a cool pit with *Picoetes*, late-flowering stage *Pelargoniums*, *Roses*, &c.

In the plant stove there is continuous work. Climbers require attention once a-week at least. The growing shoots of such plants as *Hoya carnea* and *Stephanotis floribunda* twine tightly round each other and the wires, and should not be allowed to remain so, but be untwined and tied up loosely to the wires. Such *Orchids* as *Lælia purpurata* and some of the *Cattleyas* are making vigorous root-growth; all re-potting that may be necessary must be performed at once. We have just done ours, using very turfy peat, with a little sphagnum moss added to it. Cool *Orchids*, such as the *Masdevallias*, *Odontoglossum Alexandræ*, and a few others, require very cool treatment in the hottest summer days. Ours are grown in a small span-roofed house with the end to the south, but the heat is too much for them, unless double shading is put over the glass, and this causes them to become drawn. As we have no other suitable accommodation for them they are removed to a cold frame under a north wall until the end of August. Amateurs and others who can only grow a few plants would do well to try this plan. I saw plants of *O. Alexandræ* only the other day slowly dying through being grown in a house where the temperature was too high for them, when the same plants would have grown with the utmost vigour, and with but little attention, had they been placed under a north wall in a cold frame. All the attention we give them is to tilt the lights about half an inch in the morning at six, and to shut up the frame, after damping the surface of the pots or syringing the plants overhead, at five o'clock in the afternoon.

FLOWER GARDEN.

Now that the beds are filled up they do not require much attention, except to remove dead and decaying flowers, which must be noted as weekly work for the rest of the season. In wet weather trusses of Zonal *Pelargoniums* are destroyed if withered flowers are allowed to remain in the centres of the trusses.

We have been placing permanent sticks to *Hollyhocks*, and removing all side shoots. This grand old autumn-flowering plant is seldom seen now as it should be; in many places it is grown, but in a mixed herbaceous border, where, indeed, it has a fine effect as a back-row plant; but it is generally crowded-up with other plants and shrubs, and the ground is not prepared for it. The *Hollyhock* likes a very rich deep loam to grow in, and, when well supplied with water, its gorgeous spikes towering to 10 or 15 feet above the surface of the ground have a splendid effect. We prepare a place in the kitchen garden specially for them, as also for *Phloxes* and *Gladiolus*. We have been placing sticks to the *Gladiolus*; they also look pretty well, but certainly not better than usual. We are trying some experiments with manure-waterings, but until this year not a drop of manure water was ever given to them; we fancy that it is injurious to the corms. *Phloxes* had been supported by sticks some time ago, but we looked over them, and tied any loose spikes to the supports.

We do not now grow a collection of named *Pinks*; if we did, the pipings would have been put in this morning. Our success in striking these used to be remarked upon. We always put them in after a heavy shower; a piece of ground was prepared in a shady place out of doors, and as soon as the rain came they were put out. In this way we did not lose a plant. If the pipings were taken off in dry hot weather we lost 50 per cent., or more.—J. DOUGLAS.

TO CORRESPONDENTS.

* * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

CURIOUS COINCIDENCES (Crito).—We are obliged by your bringing the paragraph in our contemporary to our notice. We were not aware that the portrait of *Thysanotus rutilans* had appeared in his pages in 1868. We admired it as published two or three months since in the "Rural New Yorker," but the flowers were so deficient in form that we supplied our artist with the "Botanical Magazine," in which the plant is figured, to correct it. Had we known it had been originally published by our contemporary we should have acknowledged it, as he ought to have done the portrait of *Odontoglossum vexillarium* which he published only last Saturday, the day on which he blames us. We employed Mr. Smith to draw and engrave that portrait, and published it in our number issued on the 15th of last May, a few weeks—not a few years—since.

BOOKS (H. D. K.).—B. S. Williams's "Choice Greenhouse and Stove Plants." It is in two pocket volumes, to be had of the author, Victoria Nursery, Holloway, London.

VAN HOUTTE'S "POMONA" (J. M. W. B.).—We do not know the number of parts it will occupy.

DESCRIPTIONS OF PLANTS (Eps).—We cannot afford space for descriptions of plants. You must refer to London's "Encyclopedia of Plants."

PELARGONIUM SPORT (H. B.).—We have seen several instances of totally different blooms on the same plant; and such sports occur in other much-crossed plants. The petals of your specimens were all shed.

COVERING WEST AND SOUTH WALLS (X.).—As you propose turning the 7-foot walls to profitable account, we would advise, in the event of your having Pears, to grow only the very early and very late sorts, as, of early kinds, Citron des Carmes and Jargonelle; and of late ones, Easter Beurré, Ne Plus Meuris, Josephine de Malines, Zéphirin Grégoire, Beurré de Rance, and Doyenné d'Hiver. We are inclined to think, in your situation is sheltered and mild, that Tea and Noisette *Roses* might be more profitable, and very likely command a better price than fruit. In this case you might plant Maréchal Niel, Céline Forestier, Lamurque, Devoniensis, Gloire de Dijon, Madame Falot, Niphétos, Safrano, and Vicomtesse de Cazes, which, in all likelihood, would give you buds more valuable than fruit. A few plants of *Jasminum nudiflorum* mixed with them would help in the autumn and midwinter weeks to afford bloom, and would, doubtless, attract customers as well as the *Roses*.

HOT WATER PIPING FOR A FORCING PIT (Subscriber's Gardener).—The hip-roofed pit that is 7 feet wide, 12 feet long, and 8 feet from the floor to the apex of the span, contains about 360 cubic feet of space, and will require 60 feet of 4-inch piping to maintain a temperature of 65° during severe frost.

GRAPE BAGS—PEARS AS DIAGONAL CORDONS FOR A WALL (Amateur).—No patent material for making Grape bags has come under our notice. The No. 3 Hexagon netting made by Haythorn, of Nottingham, is an excellent material, stouter and more durable than the ordinary gauge. To avoid rubbing the Grapes, distend each bag by fastening slight wire hoops on the inside near the bottom, and another near the top, fastening the mouth of the bag around the bunch-stalk with an elastic band. By this means the bloom remains intact, and the air plays more freely among the berries than when the bag touches the sides of the bunch. The following Pears are choice kinds that ripen in succession during seven or eight months—Jargonelle, Williams's Bon Chrétien, Desiré Cornels, Belle Julie, Marie Louise, Millot de Nancy, Beurré Bosc, Urbaniste, Comte de Flandre, Winter Nelis, Zéphirin Grégoire, Doyenné Defais, Doyenné du Comice, Duchesse d'Orléans, Knight's Monarch, Beurré Sterckmaus, Beurré de Rance, Jean de Witte, Elisa de Heyst.

PEAS (Thorney).—We never heard of any varieties of the names you mention.

SEEDLING BEGONIA (Dorsetshire).—*Begonia xanthina* is yellow-flowered, and a portrait of it is in the "Botanical Magazine." Yours is a pretty variety of it.

VEGETABLE MARROWS NOT SWELLING (Mould).—We attribute the non-swelling of the fruit after setting to the cold state of the soil, or to the cold weather; we think the former is the cause. The treatment cannot be far wrong. Try watering with weak liquid manure at a temperature of 70° to 75°. Hot weather will most likely set them right.

VINES FOR PLANTING-OUT (A Reader).—The Vines you propose planting out in autumn, and which are now in pots, we should at once shift into 10 or 11-inch pots. A fortnight afterwards reduce them to one cane each, unless you want them with more than one cane or rod, and cut the laterals to one joint each. Train the shoots or canes about 1 foot from the glass, and let the cane run to the length of 8 to 10 feet, then stop it. Keep the laterals pinched-in to one leaf. The supply of water should be liberal during the growing period, but reduce it gradually when growth is complete. Cut the laterals close-in in September, and prune the canes to the height required when the leaves have fallen.

CUCUMBERS FOR WINTER FRUITING (Idem).—To have fruit at Christmas and throughout the winter sow the seed in the first week of September. The kinds we advise are Volunteer and Telegraph. They are good, certain, and handsome.

MELONS WITH MALE FLOWERS ONLY (J. A.).—If your plants have made more than two joints of the side shoots without showing fruit we should cut away the main shoots, and train fresh shoots from the collar of the plant in their place; stopping these when they are 6 inches from the side of the frame. Probably the plants are not sufficiently advanced for the appearance of the fruit blossoms. They should fruit on the second vines, and mostly at the first or second joint of the laterals. We would not let the temperature fall lower than 65° at night, and 70° to 75° by day, with a rise from sun heat to 85° or 90°. If the temperature is too low, male flowers abound; if too high, female flowers predominate.

CARNATION SEEDLINGS DYING OFF (Frank W.).—From your description we should say your plants have died off from the attacks of wireworm or some grub in the soil used. There is no remedy but to scrutinise the soil minutely before sowing, and to have it well exposed to the air before use, turning it over frequently, and sprinkling with soot at each turning. Mix some lime rubbish with the soil. The application of soot water would tend to prevent the mischief complained of. Place some pieces of Carrot just under the soil. It is likely the grubs will leave the Carnations for the Carrot bats, when they may be taken and destroyed.

PREPARING ROSE CUTTINGS (Arthur).—Take off the cuttings as soon as the flowers are shed; the wood is then ripe. The cuttings must be of the current year's growth, without any portion of old wood. They may have

three joints or eyes; remove the leaf from the lowest one, and insert the cuttings up to the second eye in sandy soil in a frame; then keep moist, close, and shaded from sun.

PEACHES IN ORCHARD HOUSE FLAVOURLESS (*Amateur*).—We should consider the want of flavour to be due to the trees being highly fed by rich top-dressings, or manure water, and not having heat sufficient to ripen them thoroughly, or they may be kept moist when ripening; instead of having a dry atmosphere. We should preserve a dry atmosphere when ripening, and give only sufficient water at the roots.

PLANTING STRAWBERRIES (*P. T. B.*).—We should layer the runners at the first joint in 8-inch pots, and take off the point of each runner immediately the joint is layered in the pots. When the runners have filled the pots with roots cut them from the parent, and at once plant 1 foot apart, in rows 2 feet distant from each other. After the first year every alternate plant may be taken out. We should trench the ground as deeply as you have soil—two spits or more. After turning the top spit to the bottom of the trench give a good dressing of manure, and throw the bottom spit upon it. We should give, after trenching, a dressing of rotten manure and pour it in with a fork. The manure you mention will be suitable. Give as much as you can afford. It is useless taking off runners of plants that have not fruited. The first joint or runner gives the best plants. Plant them as soon as you can secure them well rooted, the earlier the better.

MELONS DAMPING-OFF (*Scott*).—The cause of the Melon plants damping-off at the collar is the leaves there overshadowing it and keeping it from receiving a due amount of air. The young shoots and leaves that cluster over the collar should be removed, so as to expose it to light and air. In dull and moist weather a light air at night is necessary to keep the moisture condensed during the night from being deposited on the leaves and stems. The collar should not be wetted or watered. Keep the laterals duly stopped to prevent the principal leaves from being crowded or overshadowed. Dust with quicklime the stems of those affected by canker. See that the lights are drip-proof.

PLANT HOUSE (*W. Sardin*).—We should decidedly prefer a half-span roof for the plant house to be built against a wall that is 5 feet 9 inches high. As you will not attempt to grow plants of a large size in such a structure, the roof need only be high enough for a tall person to pass under it. Let all the woodwork be as light as is consistent with strength. Do not let the sills touch the soil, but keep them a little above the surface by means of a few courses of brickwork, which will add very materially to the strength and durability of the building. For ventilation make an opening of 10 inches wide all along the south side or front of the ridge, fixing glazed or wooden ventilators by hinges to the ridge-bar, each ventilator to be opened or closed by an iron catch or handle perforated with holes, so as to enable you to regulate the admission of air to a nicety. Three small sliding wooden shutters fixed in the brickwork under the front sill will complete the ventilation, and answer as well as the most costly apparatus. The staging should be 2 feet wide in front, then should come a 3-feet walk, and between it and the back wall there should be a stage in three tiers, the lowest 2 feet from the ground. Continue the two lower tiers of the back stage round to the back wall at each end opposite the doors. With the exception of the path the whole of the space will thus be utilised for the plants. You are in error in supposing it is necessary to place plants near the glass to prevent the growth becoming drawn-up and attenuated. In a light and thoroughly ventilated house, with ordinary care, the plants might be grown to perfection upon the floor, but the stage is, of course, more convenient, and the plants appear to better advantage upon it. Use four rows of 4-inch piping along the entire length of the front of the house, placing them under the front shelf. Connect the flow and return pipes with the boiler by 2-inch pipes, which is the smallest size that ought ever to be used for the purpose. We do not think a glass coping along the wall from the plant house to theinery would improve the appearance of the houses, and we think it bad practice to plant a fruit tree or anything but Vines in a Vine border.

MILDEW ON VINES (*Elruep*).—This disease is prevalent in the present year. We had it in a Rose house, and dusted the Roses at least six times with sulphur before we eradicated it. A damp atmosphere with insufficient ventilation causes mildew, while a rather dry atmosphere with a current of air in the house is unfavourable to the development of this parasite. Sulphur is the only cure for it that we know. It will be desirable to paint the stems of your Vines, after they are pruned, with the following mixture:—Dissolve 2 ozs. of soft soap in a quart of water, add flowers of sulphur to make it of the consistency of thin paint, then add a little tobacco water; with this paint the Vines, working it well into all crevices with a brush.

MUSHROOMS GRUB-EATEN (*Backbarn*).—The grub is apt to assail Mushroom rooms in houses in summer, from being too close and hot. Sweep the beds clean over, water especially at the back and front, syringe the walls and pathway, give a little air, not a keen draught, and put no covering on the bed. A shady place out of doors, or a cool cellar, is the best for Mushrooms in summer.

GRAPES DISEASED (*W. F.*).—They are severely attacked by the gangrene, called by gardeners "the spot." Cut away every berry attacked, and water the roots freely twice a week, once out of the twice being with weak liquid manure, and the chink taken off all the water applied. The roots do not supply sap sufficient.

COLD PIT CONSTRUCTION (*A. P. Chester*).—Ours are sunk in the ground 2 feet, but the site is well drained. The floor is cemented, but ashes will do. The front wall is raised 6 inches above ground, or 2 feet 6 inches high, and the back wall 4 feet. The walls are 4½ inches thick, the wall plates the width of the walls, and beddled to suit the pitch. The pit is 7 feet wide, which with redrains, our lights are 3 feet 6 inches wide, and had we another to make we should have them 3 feet. Wide lights are very unwholly. The best of the sites you describe would be the S.S.W.; let the front face to that point. The lights should be 2 inches thick, and glazed with 21-oz glass.

STRIKING ROSE CUTTINGS (*Rose*).—Though you have means of supplying bottom heat, we presume you have a frame or hand-light or two. Take cuttings of the kinds you wish to propagate as soon as the first crop of flowers is shed. The cuttings should be of the wood of the current year, and are best with three eyes or buds. Cut the shoots below the lowest bud or eye, and remove the leaf which is there, but let the others remain. Insert each cutting in a 3-inch pot filled with two parts light loam, one part leaf soil, and one part sand. Set the pots on ashes in a cold frame or under a hand-light; keep the cuttings close and shaded from sun, and sprinkle lightly overhead with water every morning, replacing the light or lights immediately. In a month or six weeks they will be well rooted, and air should then be admitted, but gradually at first. Shift the plants into 5-inch pots in September,

and during the winter keep them plunged in ashes in a cold frame, with air in mild weather, but protect from severe frost. Shift the plants into 6-inch pots in April, and plunge them out of doors in a sheltered position, watering as required, and frequently giving water overhead. In September they may be placed in 8-inch pots, and in the following year they will flower if pruned in January and then introduced into the greenhouse.

HERBACEOUS CALCEOLARIAS AND CINERARIAS DYING-OFF (*Douglas*).—We do not see in what way your treatment differs from ours, only we think you allow the plants to become pot-bound. At no stage is this good. We should shift them into larger pots more frequently, and under this treatment they will require to be in 8 or 9-inch pots in February or March. Pinch out the point in the centre at the first pair of good-sized leaves. They require to be kept moist, and should be set on a cool bottom where they will be only just safe from frost, and have an abundance of air whenever the weather is mild. The dying-off at the collar probably arises from potting them too low. Pot so that the collar or neck of the plant may be a little raised in the centre of the pots, which will cause the water to drain from, not to it. Never pour the water directly on the stem or neck of the plant. In other respects we cannot improve on your treatment.

SOIL FOR PANSIES—POTTING (*P. C. S.*).—The best soil for the Pansy is three parts loam from rotting turves not less than six months old, turned over frequently, and sprinkled with soil in the turning to drive away wireworm. The loam should be of a medium texture—that is, neither heavy nor light. To this add one part leaf soil, half a part of thoroughly rotten manure, and half a part in equal proportions of sand and charcoal not larger than a hazel nut, the whole well mixed. For flowering in pots they should be potted at the end of September in 4-inch pots, well drained, and placed in a frame near the glass. Air should be admitted freely in mild weather, but keep close and covered with mats in severe frosts. Shift in February into 6 or 8-inch pots for blooming, continuing to keep them near the glass, but with abundance of air in mild weather.

RED SPIDER ON VINES (*A Subscriber*).—The chief cause of red spider is a deficiency of moisture at the roots or in the atmosphere. We should dress the border with guano, making it quite yellow all over, and wash-in the guano by watering. The floor of the house should be kept damp by sprinkling with water twice or thrice a day. If the Grapes have not begun to change colour for ripening, we should syringe them twice a day with clear rain water until they change colour. The force of the water should be directed against the under side of the leaves. Pearson's "Vine Culture under Glass" will suit you. It may be had from our office for thirteen penny postage stamps.

THRIPS ON VINES (*J. E.*).—We think that the insects on your Vines are thrips, which may be destroyed by fumigation with tobacco. Choose a calm evening, shut the house up closely, and after damping the floor, but having the foliage of the Vines dry, fill the house with tobacco smoke so densely that you cannot see the Vines from the outside; then remove the fumigating apparatus. In fumigating take care to deliver the smoke cool, not allowing the tobacco or tobacco paper to blaze. Repeat the fumigation on the next night but one, and continue to do so as long as you find a thrips alive. These insects are rather difficult to destroy when they obtain a hold, for though one or two fumigations may destroy all those in existence, other broods succeed them from their eggs; therefore keep a sharp look-out, and fumigate the house whenever a thrips is seen.

NAME OF FRUIT (*J. Green*).—Your Strawberry is Trollope's Victoria.

NAMES OF PLANTS (*W.*).—The Orchil sent two or three days ago is *Odontoglossum pulchellum*. (*G. B. C.*)—The plant is *Thalicttrum minus*, Lesser Rue-weed. We cannot name Roses or other florists' flowers. They are in leucis. (*H. P. M.*)—The same reply must be to you with this addition, we have repeatedly announced that only six specimens must be sent at a time, and you have sent nearly forty. (*E. J. E.*)—*Fumaria parviflora*, small-flowered Fumitory. (*F. D. H.*)—*Cynoglossum officina* c. (*O. Orpet*)—*Sertera depressa*; is quite hardy. (*T. Perry*)—1, *Veronica Teucrium*; 2, *V. spicata*; 3, *Erigeron speciosus*; 4, *Epilobium angustifolium*. (*W. D.*)—2, *Adiantum teucrium*; 3, *Nephrodium setigerum*; 4, Not in fruit; 5, *Pellaea hastata*.

POULTRY, BEE, AND PIGEON CHRONICLE.

DOGS IN GENERAL,

AND A VISIT TO THE HOME FOR LOST DOGS.—No. 2.

"Let Hercules himself do what he may,
The cat will mew, the dog will have his day."

Shakspeare.

I suppose that in the above lines Shakspeare wished to show, what is indeed most true, that let the great of the earth do whatever they choose—this king reign, that king be deposed, yet the little ones of the earth will in no wise be affected by them. They will go on just the same; they will have their life, their loves, their hates, their ways, and their whims under whatever king, or no king at all. Carry this reasoning to the lower animals, and how very little, indeed, is the power of the great. Look at the animal world, and the bird world; the lamb will frisk, the bird will sing just the same, however the land and timber may change owners. Let the dog only have a good master, and what cares he for king or kaiser? He will have his own enjoyments in his own little world. So, therefore,

"Let Hercules himself do what he may,
The cat will mew, the dog will have his day."

In passing, let me note how one man of genius inspired another. The latter half of the last line, from the greatest work, Hamlet, of the greatest poet of all time, found an echo in the heart of Charles Kingsley, who adapts it to another and higher purpose in his sweet and antique-sounding song beginning

"When all the world was young, lad,"

for, speaking of the hopes of youth and the enthusiasm of youth, when

"Every goose is a swan, and every lass a queen,"

he adds, remembering Shakspeare's words—

"Then hey for horse and boot, lad, and ride the world away;
Young blood must have its course, lad, and every dog his day."

Yes, and the more spirit the dog has the more eventful will be his day. You and I, my good reader, may like repose and a settled home, to sit in sunshine in our gardens during the summer, and be cozy by our firesides during the winter. But that fine, ardent, energetic lad of nineteen will not rest here, but must be off to ride over Australian plains. Well, be it so; it is all right, as saith a shrewd observer and wise man, whose letter lies before me. "We should be a strenuous lot, if, like the Hindus, we all kept in and around the paternal compound." So "to horse and boot, lad;" let "thied" have his day, let him go forth, and in future years he will have more to talk of, more to think over, and a brighter brain than the mere stay-at-home; for "Home-keeping youths have ever homely wits."

Mark next how we use the term dog. We call the boy we are proud of "a fine dog," or "a rascal of a dog;" and men with twinkling eyes and a poke in the ribs say to an old friend, "Oh, you sly dog." Then, "as kind as a dog," "as faithful as a dog." We use the word "cur" reproachfully, but he is the lowest class of dog, and has a nasty trick of biting the heels. He is the exception to the rule. Why, even "Oh, you dog," is half praise. What is an Englishman called? "John Bull," surely from the bulldog. We say of a bold plucky orator, "Ah! he has so much of the British bulldog in him."

I sometimes wish in my annual visit to the Royal Academy, that all those portraits of respectable round-faced gentlemen who have had their likenesses taken to please their wives, or to please their fellow-townsmen, or simply to add to the hereditary pictures, often mere "tenth transmitters of a foolish face"—I wish, so firesome are they in the unartistic black coat of the day, that they were all put in one room, and that visitors could go in if they chose (I wonder how many would choose)—I say I wish this could be, and in their place were portraits of good dogs (mark the good, if you please). How much more interesting than the picture of Alderman Jones, "Presented to Mrs. Jones, in grateful acknowledgment of the services of the worthy alderman in his spirited and successful endeavour to prevent the railway station being nearer his native town than full two miles." N.B.—This was actually done some years since. A portrait gallery of great men by great artists—such as Richmond's likeness of Lord Salisbury in this year's Academy—and good dogs would indeed be worthy of a visit. But there being no picture gallery of dogs, I determined to go and see the lost dogs at their Home.

This Home was originally somewhere in Holloway, but is now at Lower Wandsworth Road, Battersea Park. Wishing to pay a call there, two friends of mine, bent on walking the distance, inquired of a policeman as to the direction in which it lay. Policeman was a new one, and looked much puzzled by the question. "Home for lost Guards, sir. Yes, sir, all right, sir. Take the second turning to the right, sir." Now that turning led into St. James's Park, where, no doubt, many a gallant guardsman has lost his heart, but scarcely lost himself. But then, new policemen are in such an awkward position; as policemen they are expected to know every place, but being new, they do not know any, and they are ashamed of being thought ignorant. The greatest Englishman of the last century, who, by the way, had a deal of the bulldog in him, when asked by a lady why he had given such a wrong meaning to a word in his dictionary, truthfully answered, "From pure ignorance, madam." As it requires great courage sometimes to say "no," so all our dogs confess ignorance. Not being myself a walker, I take the train at Victoria for York Road Station on the London, Chatham, and Dover line, and in a very few minutes I am there, passing close by Battersea Park, where in olden times duels were frequently fought—then not a park, but a level dreary plain called Battersea Fields, now made an interesting and by no means dreary place, owing to the clever hand of a good gardener. Battersea Park is one of the genuine improvements around London; and then think how much the finger of time will add to the improvements, how trees and shrubs will grow, and the whole place become each year more and more park-like. Close to the station I find the Home; turning under an arch I pass on, but stop to pet a sleek cat basking and happy on a low wall, in spite of, and wholly indifferent to, the barkings fall in her ear and mine. The first thing that strikes me is the cleanliness of everything; all the paths clean, the kennels clean, the yards for exercise clean.

I walk down the centre of the kennels, where on each side of me, on low benches, are lying dogs of all varieties in different compartments: then these compartments open at the other end (I walk down a corridor on either side of the kennels) into yards wired-in, where in turns a number of dogs are let out for exercise. The separation is only a separation of sexes, not of sorts, save that the spiteful dogs are confined in kennels in another part of the yard. I was told that a great number of dogs are daily brought to the Home, and some 250 to 300 are usually there. If not claimed within a certain time they are for sale, with a due

care that they are not bought by dealers. Anyone desirous of a pet dog, and having a good judgment, or who can take one with him who has, can procure an excellent dog at a small price. Something like eight hundred were restored to their owners during the year 1872. Here we see the value of the Home, for the lost are found and welcomed home again. I own I expected to find that the greater number would be little dogs, knowing how many such are kept in London, but to my surprise they were not small pet dogs which were so very numerous, but larger dogs, and especially retrievers. A moment's reflection put me right. They are not so much London dogs as country dogs, who, like country folks, easily get lost in the vast metropolises. Poor bumpkins! they trotted off behind some vehicle; they would come to London, and, bumpkin-like, they get lost. There are almost all varieties of dog, "puppy, whelp, and bound," down to the very frequent "cur of low degree." I noticed one bob-tailed shepherd dog, with his peculiar long trot, who seemed sorely puzzled as to where his sheep could possibly have gone, and who trotted quickly and restlessly about the yard, marking friends with no one. He looked quite out of place. I longed to see him in a tree-shadowed country lane with his fleecy charge. Poor shepherd dog! There were also a few greyhounds in the Home, but by no means at home; and two Dalmatians, like school plum-puddings, for their plums (spots) were not plentiful. The many seemed happy enough, for they gambolled and played, especially the younger ones. Some were nasty fellows—noisy, irritable, senselessly and continuously barking. Some, a few, followed one round the wires, very desirous of biting. Then there were the pleading-faced dogs, who said as plainly as eye could say, "Do let me out, now, do!" There were only a few very large dogs, and also only a few very small. Here and there was a lady's pet, with a cloth coat to keep him warm; but I fear, as a rule, the little dogs in London are not lost but stolen. Some of the little ones lay on the benches close to the larger, cuddling near them for warmth, a liberty which the large ones did not seem to resent. There was the over-fat bulldog, evidently the pet of the butcher's shop, so very sleek and meaty. With me, or rather near me, in the corridor was a roughish-looking man, who peered into every kennel, evidently searching for a missing dog. Suddenly he called out, "That be 'im, sir; lor, bless 'e, sure enough that be little Fanny." And within the bars was a little crippled creature, making with voice, and eye, and tail the strongest demonstrations of affection. Note, that rough-looking man was not rough all through. The very good ones were at the Home, as they are everywhere, very few and far between, but some such there undoubtedly were.

The Home is worthy in every way of a visit, and deserves to be well supported. Anyone curious in the characters of dogs may get many a lesson, for points of character always come out in a crowd. Thus, a hot-tempered man at once loses his temper if he is in a crowd, while a sleek, easy-going, kindly-tempered man seems even to enjoy it, and cares little for the crush. Shrill-tongued parchment-faced women are always unpleasantly demonstrative in a crowd. N.B.—Let a bachelor beware of a thin-cheeked woman with only a slit for a mouth; let such a one have a pair of fiery eyes, and you have the being ready to use knife or poison. Rounded cheeks and rosy mouth imply kindness. In the crowd of dogs you could see the sensual Barnardine (see "Measure for Measure"), you could see the irritable brute, you could see the very affectionate dog, you could see the one pining for his own home, and the dog indifferent as to where he was—a very citizen of the world. One started up and thought he saw in me his master, but disappointment soon shadowed his face, and he lay down with "He has not come yet, I hope he will come soon" in his mind.

The manager showed me the various parts of the Home, and with him and if I was pleased. It is a good place, the result of kind thoughts towards the animals next to man in brain and heart. You see in this Home one of the results of Christianity. A Home for Lost Dogs! How much better than the dog pit! how much better than the tin kettle tied to the tail of the poor straying dog! how much better than the kicks and curses of cruel men! how much better than the stones of cruel boys! Poor weary, dirt-soiled dogs are fed and made comfortable, the weary and the exhausted are rested and refreshed. Then there is now hope that many a master or mistress who prizes dogs may have them returned, and a favourite dog is, if lost, not only much missed but much wanted. May the Home prosper, may its funds increase, and so its means of usefulness be extended. A home for the lost, but when there the lost are found.—WILTSHIRE RECTOR.

OXFORD POULTRY AND PIGEON SHOW.—His Royal Highness Prince Leopold has consented to honour the Oxford Show with his patronage, and has presented a silver cup, value £5, for the best pen of Dorkings irrespective of colour. The Committee intend having a class for Malays; the following gentlemen having promised to subscribe for a cup—viz., Rev. N. J. Ridley, 10s.; Rev. A. G. Brooke, 10s.; Mr. R. Hawkins, 10s.; Mr.

G. Burnell, 10s.; Mr. J. S. Rooth, 10s.; Rev. G. S. Cruwys and Mr. Herrieff kindly giving one guinea each for a cup for Clean-legged Black Bantams, not forgetting Mr. Billett's subscription for the same. Thirty-four silver cups or pieces of plate will be awarded. The number of classes is increased from forty-nine to sixty-three, including a class for local fanciers.

MANAGEMENT OF SITTING HENS.

The sitting hens should be very clean and free from vermin, which is one of the great secrets of successful poultry-rearing. It is impossible for a hen to sit well if she is tormented in this way, and the little chicks get infested with them and cannot thrive, sometimes dying off by whole broods. As a proof of this being the cause, Cochins or Brahmans rarely die off in this manner, because the young chicks have not feathers enough to harbour vermin. I have also been very often asked to call and see a lot of chickens that have been doing badly, though fed upon the best food money could buy; and on taking them up have generally found them covered with lice, which all quickly-feathering breeds are subject to. The best thing I know of in such a case is to mix a very few drops of carbolic acid with powdered brimstone, mixing or rubbing well together, and putting no more of the acid than will mix up dry with the brimstone; give them a few dustings of this, and you will not see any more of the little plagues for some time, while the chicks will recover as if by magic. I also find it a good plan to water the house all over with water in which a little of the acid has been mixed, which purifies it as well as destroys all insect life.

I prefer to set my own hens out of doors in the same covered coop I mean the bird with her chickens to occupy after hatching, and allow her to come off at pleasure. I do not believe in their needing to come off every day, as many people make a practice of taking them off—the food they eat lasts much longer than when they are taking plenty of exercise, and if Dorking hens at least be left to their own will, they will only come off once in two or three days. If you put a feeding hopper there will always be food ready for them. If the weather is very dry do not forget to sprinkle the eggs a few times, and pour plenty of water round the nest when the hen is hatching. I never take the chickens away, not being partial to chickens roasted on the hob or before the fire at that tender age. As soon, however, as all the chickens are out of the shell and are quite dry they should be put into a clean nest, though this is still better done the day before hatching; but they are better for not being fed till twenty-four hours old.—(*Colonial Farmer.*)

[We are always glad to get information from every source, and therefore gladly cull from our transatlantic brethren, and venture to make such remarks as seem called for. One of the most certain plans to avoid vermin in nests is to let hens sit on the ground. A butter-tub cut in half, and the top and bottom knocked out, makes two good sitting boxes. As the birds do not sit outdoors let a large sod of growing grass be cut, on which place the half tub, give a little clean straw, on which place the hen, putting the eggs under her. Let the top be covered with a frame of wire netting. All hens should sit in a house where they are quiet and secure from interruption from other fowls. The hens should have access to dust or road grit when they are off. When fowls have plenty of dust and road grit they will have no vermin. When a hen comes off her nest, all except the tub or box should be destroyed, and the tub thoroughly cleansed with boiling water, and carbolic soap if desired. We do not at all approve of the hens sitting in the rips in which the chickens are to live. We keep them fresh and thoroughly cleansed to receive the chickens. Nor do we approve of the plan of leaving the hens two or three days on their eggs without coming off. We take ours off regularly every morning, and they look for the attention.—Eds.]

LINCOLN POULTRY SHOW.

This Show, although the first that has taken place in the locality, obtained an exceedingly good entry as to numbers, and comprised pens from most of the celebrated breeders both of poultry and Pigeons. There was also a very good collection of eggs and butter exhibited in the tent, besides which a large number of excellent Rabbits competed for the special prizes allotted to that division of the Show. The tent was unusually spacious, and very well arranged throughout. Messrs. Turner supplied their well-known exhibition pens, and every specimen was seen to the greatest advantage. The Committee, a well-appointed body, worked with a will, evidently determined by personal supervision to enforce the regulations of the Show to the very letter. No small portion of the success of this meeting was attributable to the courtesy and methodical promptitude with which the whole of the correspondence was carried out by the Honorary Secretary.

During the whole of the present season *Dorkings* have not before shown as strong an entry as they did at Lincoln, Mr. White standing first in cocks, and Mr. Lingwood first with a well-shown hen. In the classes for Buff *Cochins* Mr. Taylor, of Man-

chester, took precedence in both cock and hen classes, the hen taking also the silver cup. In the variety *Cochin* class, Mr. Woodgate's grand White cock stood first, and Mr. Darby's splendid Black hen was easily first in her class. In Dark *Brahmas* Mr. Ansdell had it pretty much his own way with birds now so generally successful. The Light *Brahmas* were not nearly so good as the Dark ones, but the *Spanish* classes were such as to tax severely the discrimination of the Judges; at this season such excellent classes throughout are exceedingly rare. For this breed Mr. Powell took the cup with a most extraordinary young hen, in admirable form for competition. *Creve-Coeurs* were most extraordinary classes, some of the cocks being as well built as *Dorkings*. Golden-spangled were the best of the *Hamburgh* classes; the Golden-pencilled and Black were also of high merit. Both *Game* fowls and *Game Bantams* were well represented. In the Variety class Golden Polish stood first, Black *Hamburghs* second, and Malays third. Among the *Bantams* we noticed some Silver-laced that were conspicuous for the purity of the ground colour, but wanting the rich iridescent character of the lacing that marked the breed as shown some twenty years back.

Aylesbury Ducks were remarkably good both as to the entry and their general good quality; the Duck cup being given to this variety. *Geese* were decidedly superior; but, as may always be fairly anticipated at this season of the year, the *Turkey* entry consisted of only a single pen.

A glorious rivalry prevailed throughout the *Pigeons*, Messrs. Harvey, Pulton, Loversidge, Watts, and Yardley sending their choicest show birds.

The weather, we are glad to say, was satisfactory, and the arboretum grounds tended much to enhance the satisfaction of visitors.

The *Poultry Judges* were Messrs. Hewitt and Teebay; and Mr. Esquilant awarded the *Rabbit* and *Pigeon* prizes. We published the prize list last week.

OUNDLE POULTRY SHOW.

This meeting, which was held on the 11th inst., was very satisfactory, and, as the weather was exceedingly fine, the visitors were more numerous than on any previous occasion. It will be remembered by many of our readers that the last year's show was, on the contrary, marked by severe thunderstorms, and consequently the receipts were comparatively small. We can also congratulate the Committee not only on an increase of entries, but also on the quality of the poultry and Pigeons exhibited being such as is rarely surpassed even at exhibitions with double the number of specimens. An excellent tent fitted with Messrs. Turner's well-known exhibition pens placed all the birds on an equal footing for inspection.

All the classes of *Grey Dorkings* were well filled, and the competition, as is usual at Oundle, was very close in these breeds. It was a matter of regret to find that many of the *Grey Dorking* chickens, though very early hatched and well grown, were intolerably sooty-footed—a feature that necessarily prevents position in the prize list. Though fast getting into moult, many of the *Game* fowls were of great merit, and it may be safely said such a numerous and first-class collection of *Spanish* hens is very rarely to be met with. *Cochins* were large classes, and the birds were excellent. In *Cochin* cocks the first prize went to a Buff, and the second to Partridge-coloured; and in the hen class Whites of high quality stood first, the Buffs taking the remaining prizes. In a capital class of *Cochin* chickens, at once well grown and in first-rate condition, the first and second prizes went to Whites, and the third to Partridge-feathered. *Brahmas* were few, and some so exhausted by over-exhibition as to enforce rest if they are intended for future competition. The Spangled proved much better than the Pencilled *Hamburghs*, the Golden-spangled being especially fine. In *Game Bantams* a pen of superior Red Piles was successful, closely pressed, however, by Black Reds. A single pen of Golden-laced *Sebrights* constituted the whole of the entries in the Variety Bantam class! In an especially good class for any other breed, Silver *Polands*, *Creve Coeurs*, and Golden-spangled *Polands* took the prizes in the order named. *Geese*, *Turkeys*, and *Ducks* were well shown; in the first-named class a pen of Canada *Geese* in extremely good feather stood first. The *Aylesbury Ducks* proved unusually good.

The *Rabbits* were of far quality throughout.

In *Pigeons* the competition was far greater than on any previous occasion. A peculiarity of this Show is that in Pigeons each entry has to consist of three pens, the varieties being left entirely to the discretion of the exhibitors. It certainly gives considerable scope for entries, and contributes much to the interest of this portion of the Show. The first prize was taken by White *Pouters*, Black *Barbs*, and foreign *White Owls*. The second prize was given to White *Pouters*, Red *Barbs*, and *White Fantails*. An extra prize, a silver cup, for the exhibitor winning most poultry prizes, was very warmly contested, the principal competitors being Mrs. Deacon, of Polbrook Hall, and Mr. Yardley, of Birmingham. Mrs. Deacon secured three first and four second prizes, Mr. Yardley taking four first, three second,

and a third. The birds were well attended to, and the Show proved very successful.

DORRINGS.—*Hens*—1, Rev. E. Bartrum, Berkhamstead. 2, J. Longland, Gleadon. 3, O. E. Cresswell, Bagshot. *he*, R. Wood, jun., Clapton (2); J. White, Warbury, Northampton. *Pullets*—1, L. B. Calcott, Oundle. 2, J. Longland.

DORRINGS.—*Cock*—1, T. C. Burnell, Mischeldere. 2, J. Longland. 3, E. W. Southwood, Fakenham. *he*, J. White, Warbury. R. Wood, jun. *Cockerel*—1 and 2, Rev. E. Bartrum. *c*, J. Longland (2); R. Wood, jun.

GAME.—*Hens*—1, H. Yardley, Birmingham. 2, S. Deacon, jun., Wellingborough. 3, H. Lotan, Oundle. *c*, S. Deacon, jun.; Mrs. Deacon. *Pullets*—1, Mrs. Deacon. 2 and *he*, H. Lotan.

GAME.—*Cock*—1, 3, and *c*, H. Lotan. 2, Mrs. Deacon. *he*, H. Yardley. *Cockerel*—1, S. Deacon, jun., Wellingborough. 2, H. Lotan.

SPANISH.—*Black.*—*Hens*—1, W. R. Bull, Newport Pagnell. 2, H. Yardley. 3, M. Brown, Akkethley. *he*, J. Nash, Walsall.

SPANISH.—*Black.*—*Cock*—1, W. R. Bull. 2, Withheld. *Chickens*—1, W. R. Bull.

Palmer (Dragoons). 2, — Marshall, Peterborough.

JUDGE.—Mr. John Douglas, The Aviaries, Clumber, Worksop.

TESTIMONIAL TO MR. VAN HAANSBERGEN, OF NEWCASTLE-UPON-TYNE.

I have just had the pleasure of placing in the hands of Mr. Van Haansbergen a very handsome marble dining-room timepiece, on his resignation as Honorary Secretary and Treasurer to the Northern Columbarian Society, Newcastle-upon-Tyne. It will be remembered that Mr. Haansbergen took a most prominent part in the formation of this Society—in fact, he was almost the founder of it. From its commencement he held the joint offices of Honorary Secretary and Treasurer until last February, when he resigned solely on account of business engage-

ments. As soon as his resignation became known Mr. James Watts, of Birmingham, reminded the members that they were losing the services of one of the best, if not the best of secretaries, honorary or otherwise, and that we ought not to be unmindful of his unflinching energy. Such an appeal was at once responded to by most of the members. The testimonial was forwarded to me by Mr. Watts for presentation on behalf of the subscribers. It was supplied by Mr. T. Leighton, Snow Hill, Birmingham, and bears the following inscription on a silver tablet—"Presented by the Members of the Northern Columbarian Society to W. B. Van Haansbergen, Esq., in recognition of his valuable services as Honorary Secretary of the Society."—JOHN G. DUNN.

Mr. Haansbergen acknowledged the receipt of the testimonial in a letter to Mr. Dunn, of which the following is a copy—"Will you permit me to express my great pleasure at receiving, and to tender my sincere thanks for, a most handsome present which has been presented to me by the members of the Northern Columbarian Society, in recognition of what they are pleased to term my valued services as Honorary Secretary to their Society since its formation until the beginning of the present year, when, owing to other engagements, I was obliged to retire from taking an active part in the management of the Society, although I retain as great an interest as ever in its welfare, and am glad to see, from the large number of new members who have joined it, that there is every probability of this year's exhibition being an improvement upon the very good one of last. I believe Mr. James Watts, of Hazlewell Hall, King's Heath, near Birmingham, was the prime mover in originating this testimonial. Whether this be the case or not, I wish to convey to him my especial thanks for the kind manner in which he has taken so much trouble in selecting the beautiful marble timepiece (which is the form the testimonial takes), and it does great credit to his good taste. It will always afford me pleasure on looking upon it, by recalling to my memory the many new friends I made since the establishment of the Society. Wishing success to the Society, such as I have no doubt it will attain under its present able management, I remain, &c.—W. B. VAN HAANSBERGEN."

HIVE WITHOUT DRONES.

We are the possessors of a hive, which, though apparently in a most prosperous condition (the bees gathering honey and pollen, the latter in such abundance as to lead us to think that breeding must be progressing very rapidly, while the hive is crowded to such an extent that late in the evening the bees cluster thickly outside the entrance), yet not a single drone has made its appearance up to this advanced period of the season. To what cause can this absence of drones be attributed? Even if a swarm should now come off, it would have a very small chance of wintering. We have, it is true, in our neighbourhood an abundance of heather, to which the bees might be sent in August; but unless the weather should prove exceedingly favourable, we fear that it would be of little avail. The hive is of straw, and of large dimensions. Do you advise our putting on supers or placing boxes underneath?—ANXIOUS BEE-KEEPERS.

We can hardly tell how to account for the non-appearance of drones in a colony so prosperous as you state yours to be. We should imagine that in the early part of the summer it must have been in a very backward state, and that it is only of late the bees have become so numerous. As there was but little prospect of their being able to throw off a swarm, no drones were allowed to come to maturity; probably you may yet see them. A swarm now would be scarcely likely to construct comb sufficient for surviving the winter, unless copious supplies of artificial food were given. It would be better to put on a super, which, if not filled with honey, may have some combs built in it; if so, the super must be taken off in September, and carefully kept in a moderately warm place, to be put on in the following spring. A box placed beneath the stock would also, most probably, prevent a swarm leaving, but it must be removed before winter.—EUS.

THE ITALIAN BEE.

In unpropitious years one learns the worth and superiority of many of the productions of nature, which in good years are not so apparent, owing to the abundance of the yield. It is thus with the Italian bee. I admit that I did oppose the introduction of that bee. Yet the past year, the worst we have had in thirty years, has altered my opinion. Now, from the fullest examination, I believe the Italian to be the race most suitable to Germany. Whether those Italians reared artificially by Herr Vogel are equal to the native Italian, is yet in my mind a matter of doubt. The appearance is there, but that does not make the Italian bee. In the spring of this year I had sixteen stands alike as to numbers and quantity of food. Four of these were Italians, and the remaining twelve German bees. During the fine days of March they all flew alike, and my hope was consequently much raised to obtain this year a large yield. Then came the bad days of April. Were there some few good

hours during the dry, they were invariably followed by cold winds or wet weather. With the opening of April, my sixteen stocks during propitious moments flew strong.

But what did I live to see? All the patris of the garden, and the ground around the hive, were covered with German bees, yet no Italians were to be found among them. I then watched the fly-holes. Out of all the hives many bees flew, the Italians, however, alone returning. It was a rarity for the German bees to return to the hive. The natural result was, that the German stocks were becoming weaker and weaker, while with the Italians there was no diminution apparent; further, by the end of April, the German bees had no brood, while the Italians were rich in brood. May was like April. My German stocks had become so weak that, except in the warm hours of the day, not a bee was to be seen. The Italians, on the contrary, increased in strength from day to day, and by the end of May began building comb. Long before this I began to feed the German bees, so as to keep them alive. On the 19th of June the raspberries began to bloom. The weather became warmer. The Italians began with their whole strength to gather from the raspberries. The weak German stocks were able to gather little. On the 20th of June the *Acacia* began to bloom, but its blossoms were not as rich this year in honey as they had been in former years, the frost having destroyed fully one-half of the blossoms. The Italians now developed daily a stronger flight as the young bees made their appearance. After eight days they ascended to the surplus honey-rooms and built them half full of comb. The German bees now only began to have large supplies of brood. When on the 8th of July, the Linden began to blossom, and the Italians were so strong that I began to expect them to swarm, the German bees had also become stronger, and were labouring rather industriously on the Linden; yet the most of the honey brought into the hive was used for feeding the young brood; there was none stored of any account. With the end of the Linden blossoms the harvest was practically over; still the German stocks continued to increase in numbers, so that by the end of August they were over-populous. The Italians had at that time filled all the honey-room with honey, about 30 lbs., and in the brood-chambers there was a superabundance for winter use. When at the end of August I inspected also the German stands, I was astonished. All the stocks were in arrears, so that in order to winter them I had to feed them strongly. Had I only Italians, the year 1871 would have been for me a good ordinary one, as four stocks of this species would have given me a yield of 112 lbs. of honey.—*Bienenzeitung*.)

THE SILK FROM SILKWORMS.

To make it available for use, ten cocoons should be put in a basin of warm water (this will not kill the chrysalis); the threads from each can then be easily found, and should be twisted together and wound round a reel 3 feet in diameter; this will fit the weaver's loom. The individual threads will easily cement together, for they are very gummy, and if wound in this way, will scarcely ever break. A few years ago we had 5000 silkworms in this parish; the school children wound the silk, and Mr. Smith, I think, of Coventry, offered us 5s. a-pound for it. We never got a pound weight, and so he did not have it; but in one of his letters he said it was far better than foreign silk. It was shown at the Coventry Museum, and especially noticed in the newspapers. Afterwards it was sent to France to dress the wounds of the soldiers in the late war.—*J. SHELSWELL.*

PREPARING WAX FOR MAKING WAX FLOWERS.

The material or wax in its crude state is unfit for modelling purposes: it requires to be prepared as follows, that is, if the modeller is desirous of preparing his own material, otherwise it may be purchased ready made for use at any artificial florist's.

Procure some of the purest beeswax, and having first cut it in pieces, place it in a vessel and dissolve by means of heat. When dissolved, add Venice turpentine in the proportion of 2 ozs. to each pound of wax. The addition of the turpentine renders it of a softer nature, and prevents it from cracking in the mould, as it would be apt to do if used otherwise. The modeller can impart any colour to the dissolved wax by rubbing together in a vessel a small quantity of the particular colour required, mixed with olive oil with a portion of the liquid wax, until it gets hard by cooling, when it should be well stirred into the body of the dissolved wax. The liquid is strained through muslin to remove impurities, and is then fit for use.

A mould of the fruit, &c., desired to be copied is next required. This is generally made from plaster of Paris, and consists of two, three, four, and even more separate pieces, according to the form and size of the fruit to be modelled. It is obtained in this way.—First construct a card form, somewhat like a collar box, about 1 inch or so larger than the fruit to be copied. Then mix with water such a quantity of plaster of Paris as will be of a moderate thickness; pour just as much of this into the form as will fill to the fruit, which has been previously olive-oiled, to sink only half way in the plaster. Having allowed

some time for it to get set, remove the paper and make a few holes on and around the edge of the mould. Then scrape the edge quite smooth, and re-oil the uncovered part of the fruit edge of the mould, replace the form, and pour on the fruit as much plaster as will be of an equal thickness to the first part of mould. Let this also stand for some time, then take off the paper form and the mould is complete. By giving the first half of mould more or less "cup-like holes," the second part will receive a similar number of projections, which, fitting into the cavities, allow the parts to be exactly placed together, and render the mould more secure.

Leaf moulds are made by giving the leaf (which should be first made quite clean, and then oiled, and placed face-upwards on a sheet of paper), first thin, then thicker, coatings of plaster, allowing a little time for the first coat to become set before giving it the second, and so on, until the mould has acquired the requisite thickness. The face of the leaf only should be covered with the plaster.

Having shown how to obtain the fruit and leaf moulds, I will now describe the method of using them. Before doing so, however, I wish to observe that no moulds should be used before they are thoroughly set or hardened, and that preparatory to using the mould, it should be placed in hot water for a few minutes, and then carefully wiped dry with a soft cloth. On casting, take one half of the mould in the left hand and pour in the liquid wax so as to nearly fill the hollow; then quickly place on the other part, in such a way that the projections of the one fit into the cavities of the other part of the mould. Hold both parts tightly together, and gently turn the mould in the hand so that the wax may be disposed on the inside evenly. Having allowed some little time to elapse, place the mould in hot water for about two or three minutes, then take it out and separate the parts carefully, and remove the fruit as gently as possible. Should there be any roughness on the fruit, it can be easily removed by rubbing it with a flannel dipped in turpentine.

Wax leaves may be painted green by means of Prussian blue, chrome, and burnt sienna, and polished, when necessary, by means of a soft brush. The stems of fruit are made from wire covered with wax of the required colour.

The characteristics of both fruit and leaves are mostly produced by the colouring and its various modes of application; to give rules for such would be but waste of time, and only tend to mystify the reader. Practice and study of the works of Nature alone will enable the reader to acquire any proficiency in this art. I may mention, however, by way of a guide, that most fruits require a body tint according to the particular colour required, and that all colours must dry on the wax before any decision can be pronounced as to the correctness of tint. If the modeller always endeavours to copy Nature in all her parts, so that each part when taken conjointly shall resemble the whole, he will not only achieve but deserve success.—*SULYAN.—(English Mechanic and World of Science.)*

OUR LETTER BOX.

PRESERVING EGGS FOR WINTER USE (St. Edmund).—You must preserve your eggs by putting them in slaked lime in a pan, layer upon layer, till the pan is full. You must put them in fresh, and they will keep so. It is the generally received opinion that Ducks must have a depth of at least 12 inches of water. Observation will show you we are right, and yours is, we believe a solitary case. The Rabbit is an uncommon case, but those who breed from bantock stock frequently meet with these sports.

COLOURS OF CREE-COERS (L. S.).—Cree-Coers should be quite black. Both cocks and hens get white feathers in their top-knots as they grow older, but they are a great disadvantage in competition. White feathers cannot be excluded out of the top-knot, and any other colour is a positive disqualification.

CHICKENS NOT EATING AND ATING (L. W. P.).—It may be your chickens suffer from the seeds they pick, but as a rule they improve in condition on new-mown land. Change their food. Give them meal mowing and evening, slaked with milk, some Indian corn or whole barley twice between these meals, and discontinue the scraps for a time. The rains will probably do them good. Drought is bad for them. Give them cauphor in all their water, and supply their runs with road grit.

DONCASTER AND BOSTON POULTRY SHOWS.—T. S. Adsett, Esq., Cowley Mount, Lancashire, informs us that he won the first prize for Dark Brahms at Doncaster, and the silver cup for the same variety at Boston. We publish the reports as sent to us.

POULTRY FOOD (Dover).—Do not be deceived by a delusive term. "Middlings" are not so good as barley meal, being part of the ground grain that is taken from the meal. If it were as good as barley meal it would not be sold at half the price. We have long sought for some cheap food that was as good and nutritious as the dearer ones, but we are still seeking. We had nothing so cheap as the best food. In such the weight is made-up of feeding stuff, in the lower priced it is made-up of "offal." Profitable food mixes into dough or paste, it is smooth; but the cheaper and less-feeding is rough when wetted, and looks as though fine-cut chaff were mixed with it. The fowls do not like it.

EGG-EATING HEN—SWOLLEN CROP (Idem).—There is no cure for a hen that eats the eggs on which she is sitting, but we are bound to say it is a very unusual thing—so much so, that we advise you to kill the hen as soon as her three chickens are fit to leave her. She will always do it. The swollen crop may be reduced, if not cured, by holding the fowl by the legs, head downwards, till the crop has emptied itself from the mouth; the bird must then be shut up and fed very sparingly, and only with a small quantity at a time. It must have water only twice per day, and then very little. If the crop still has so down you may put alum in the water. It will be some time before it regains its normal state, but we have seldom known this treatment fail.

EGGS BLOOD-STREAKED (E. J. B.).—You do not say whether the streaks were on the shell or in the egg. The latter is not an uncommon case, but it is a bad sign, and shows there is something wrong about the bird that lays them. If the streaks are on the shell they betoken fever. Castor oil given internally and administered with a feather into the egg-organs will cure it. In all cases of fever, lettuces are excellent food. It is hard to find a cause for the paralysis. An injury on the back will cause it; being egg-bound will do so also. We advise you, as soon as you see this, to take a wing feather, dip it in castor oil till it is thoroughly saturated, and then introduce it into the egg-passage as far as it will go without hindrance. We believe you will then remove the complaint, by causing an egg to be laid. You say she is only a year old; these are, perhaps, her first eggs. If so, you may well expect to save her. She is little more than a pullet.

LINCOLN POULTRY SHOW.—One of the pair of Ayresbury Ducks entered for this Show by Mr. S. H. Harris, of Casgarra, Carwall, was dead in the hamper when delivered on the Show ground, and therefore, strictly speaking, this pen should have been marked "absent," in the catalogue.—THE POULTRY SECRETARY.

INCUBATORS (H. G. O.).—We cannot give any information about them. Any one will hatch, but then the difficulties commence. We never knew any one who reared chickens artificially hatched except at a fearful loss.

RUCKWHEAT, &C., FOR PIGEONS—SEX OF EGGS (F. W. H.).—We have known Pigeons fed on this, but we never used it for our own birds. In regard to the disease in Pigeons known as eanker, see our reply in last week's "Letter Box." As to which egg produces the cock bird, the one laid first or second, we believe there is no rule. Very often both the young are cocks, occasionally both are hens.

CANARY'S LEG-WEAKNESS (Constant Reader).—I fear there is no permanent relief for your ailing bird, but I think the symptoms would be ameliorated by giving a drop or two of cod-liver oil. Hold the bird in the left hand, and if you cannot manage to open its mouth and administer the oil at the same time (which can be done by taking up sufficient on a blunt-pointed little stick) get some one to assist you by opening the patient's mouth, when a little nerve and a steady hand will do the rest. Another method is to remove the water vessel, say from breakfast time till the middle of the day, three or four hours, when you can replace it, or one kept for the purpose, with plenty of oil floating on the surface of the water. The patient will then drink its medicine without assistance. Some birds soon get to like it. I once had a very valuable Variegated Jonque Norwich cock which appeared hopelessly gone, and which I turned over to the care of my wife. I do not know whether it is the result of practice acquired in the nursing, but for artistic management with a spoon recommend me to a woman. The way in which a woman tucks up one of those little bundles in the nursery, pinions its fat hands, and prepares to administer physic is a gift peculiar to the sex. No sooner is the mouth open than in goes the spoon and the operation is over. I should be afraid of hitting the bundle in a wrong place. My wife appeared to have no difficulty in managing this bird, which subsequently became the father of a family, and lived almost entirely on cod-liver oil.—W. A. BLAKSTON.

BULLFINCH AND CANARY EGGS (M. G.).—After a horned Canary we may expect anything. Among other freaks of nature I have heard of a remarkable Linnet Mule. I was told it would be sure to beat anything likely to appear this season if the prize-lists could only be made to suit the bird, "myast (most) legs to win," as my informant said, "for this yale's (one's) gotten fower (four)!" The notes on Bullfinch and Canary Mules in the "Letter Box" a short time back attracted the attention of a correspondent, who writes:—"I had a hen Bullfinch which I had reared by hand. Seeing her evidently preparing to nest, I introduced into her cage a very vigorous Buff-breasted Norwich Canary, which paired with her successfully. She behaved in every way as a Canary; if anything she seemed more so. She dropped the first egg in the case bottom, and finding it broken I examined it: it was to all appearance properly impregnated. I that evening stewed the case bottom with fine sawdust, and so saved the remaining eggs—five, some of which she laid in the nest, and others on the sawdust. These eggs I placed a laid under different Canaries, but they all proved infertile. I gave the Bullfinch some bad Canary eggs, which she set quite carefully, and after a week or two had clasped I again tried her with the same Canary, with precisely the same result. She again laid six eggs, all infertile." "M. G." also, in reply to whom the notes in the "Letter Box" appeared, writes, "I was not successful with the Canary and Bullfinch. The Canary had five eggs, which she sat for fifteen days. She was a small hen, and did not cover well. Some time after she laid again, and the Bullfinch made a hole in the egg. She is now sitting on two eggs, and never stirrs except to eat, and that seldom." So far, then, the weight of evidence in this *versata quæstio* is against the production of Canary and Goldfinch Mules. Other Finches also will mate with the Canary readily, but the result is *nil*.—W. A. BLAKSTON.

YOUNG CANARIES LOSING FEATHERS (A Reader).—If I shut some young Canaries into a cage with their father, and I noticed that one of them became rather short of feather, I do not know that I should suspect the old bird of the theft, because young ones are very apt to pick one another, and when they once begin it is extremely difficult to get them to discontinue the practice—in fact, they will continue to pick as long as there is anything to pick at; but if I observed that one of them was "minus his tail, with blood all about the tips of its wings and the roots of the tail, and I noticed blood on the cock's beak," I should consider that strong presumptive evidence of his guilt, and I do not think an action for libel would lie if I charged him with the crime. At all events, I should lock him up on suspicion. You have done quite right to remove him, and if the young ones can only pick a little there is not much fear that you will rear them. Give them plenty of soft food, such as stale bread soaked in water, and squeezed dry, or neatly so; add to this a little chopped egg and a little mawseed. Supply white canary seed, and when you notice that they can crack it, reduce the quantity of soft food and put them on hard seed entirely. I should not, as a matter of choice, always allow young ones to be fed through the bars of another cage hung on to the other; but when they are so ill used, what else can you do? In such cases all depends on the ingenuity of the breeder; and any contrivance which, while it protects them, gives the old birds access to them for feeding purposes, is an admissible adjunct to the breeding cage. The method you have adopted is very common, and you will see by referring to my A. P. C. Canary papers in previous numbers of the Journal, that I recommend the wires of the breeding cage to be inserted at such a distance as will admit of the birds getting their heads through without fear of their bodies following, or, on the other hand, strangling themselves. You must be careful, however, to put the perch on which the young ones will have to sit at such a distance from the wires of their nursery cage that they will either have to stretch their necks a little, or go to the wires to be fed, or else, when they are resting after a meal, the cock will be sure to help himself to any juicy little tail feather he can

reach. The life of a Canary, from the shell to the show-cage, is beset on all sides with dangers, and were it not for the great number of deaths which occur, an ordinary room would scarcely hold the produce of a season.—W. A. BLAKSTON.

SILKWOOLS (E. M. N.).—Thanks for your note, but our correspondent needs more details of the size of marketable skeins, &c.

PAYNE'S HIVES (T. M. P.).—Either Messrs. Neighbour, High Holborn, London, or Mr. W. J. Pettitt, Apicultural Institute, Dover.

SALE OF HONEY (A English Bee-keeper).—Write to Messrs. Neighbour, Messrs. Fortnum & Mason, and other Italian warehousemen, whose directions you can find in Kelly's "Post-office Directory."

POT PATRIE (L. Jackson).—You must mix your rose petals (leaves as you call them) as follows:—Gather the petals of the most fragrant kinds of roses, with which other flowers may be mixed at pleasure in smaller proportion; spread them out to dry in the sun, or in a warm room; sprinkle a little salt on them, and put them into a jar, in which they are to be kept covered up till wanted for use. Take of these rose leaves 4 ozs.; dried lavender flowers, 8 ozs.; vanilla, cloves, storax, and benzoin, all bruised, of each 1 drachm; ambergris, 20 grains; otto of roses, twenty drops. Mix.

ROSE LEAVES (St. Edmund).—See the above answer.

REMARKS.

- 9th.—Fair all day, but occasionally cloudy all through the day.
 - 10th.—Bright and fine, with a pleasant breeze all day.
 - 11th.—Fine day, but slightly clouded in the after part of the day.
 - 12th.—Three or four slight showers, but very fine between.
 - 13th.—Fine early, but rain commencing at 10.30 A.M., and continuing to fall, more or less heavily, all the day.
 - 14th.—Showery in morning, but very fine after.
 - 15th.—Heavy showers in morning, with thunder between 11.3 and 11.18 A.M., thunder also at 2.13; fine evening, distant lightning in the south at 9.13 P.M.
- A moderately fine week, temperature very similar to the preceding four weeks. Very heavy rain on 13th.—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 16.

We are now getting into full swing with the standard and bush fruits, all of which are well supplied and of good quality, especially Currants, Raspberries, and Strawberries. The latter are very abundant and can be had at very low figures. French goods are also freely offered, comprising Peaches, Nectarines, Cherries, Apricots, Plums, and Melons. Potatoes are showing symptoms of disease both in rounds and kidneys.

POULTRY MARKET.—JULY 16.

THERE is a tendency to lower prices, and a change may be looked for daily. This season will for a long time be remembered as a bad hatch for fowls and Ducks.

WEEKLY CALENDAR.

From observations taken near London during forty-three years, the average day temperature of the week is 74.6; and its night temperature 50.4. The greatest heat was 95, on the 24th, 1838; and the lowest cold 31, on the 29th, 1838. The greatest fall of rain was 1.18 inch.

STRAWBERRY GOSSIP.

THE time of gathering Strawberries is the time for judgment and comparison, and as soon as the gathering is over it is time to prepare for future crops. There can, therefore, be little risk of an anachronism by essaying a little Strawberry gossip in the month of July—the month alike for eating the fruit and planting the plants.

In the early period of the year, after the deluge of the autumn and winter months, I never saw Strawberries present a more miserable and starved appearance, and had there been a scant crop, no one could have justly grumbled, considering the absence of autumn sun and the consequent immature state of the crowns. There has, however, been such a bountiful yield generally, that owners and growers, and Strawberry lovers, may rejoice indeed. The fact seems now about demonstrated, that extreme frost is more detrimental to this fruit than extreme wet. I have seen the foliage of plants rotted and perished by wet to such an extent that hardly a vestige of green could be found on the beds, and following this one of the finest returns of fruit ever gathered; but I have never seen the foliage so frozen and perished by a dry continuous blast without the crop following suffering proportionably. Extreme wet, then, appears to be less injurious than extreme frost. Strawberry-forcers may perhaps gather a hint from this, and turn it to account in storing their prepared plants. I know, from a pretty extensive experience, that damage may be done by packing the pots high and dry, and that there is much less danger in plunging the pots upright in a sheltered position, providing the heavy rain and melting snow can by some means be shunted off them, as certainly the plants cannot so well resist the damaging effects of a torrent of wet in pots as when planted in the open ground. The reason for this is obvious. But the lesson is given that they will suffer from drought and frost in autumn and winter more than from wet, and that many failures in Strawberry-forcing may be attributed to letting the pots get too dry in ripening and resting. As to moisture, in this matter the "happy medium" is the safest and the best.

I have only had one kind of Strawberry in the garden that could in any manner deal with the enormous amount of wet which the ever-dripping clouds poured upon it, and that is the Vicomtesse Henriette de Thury. But stay, I am a trifle too fast. Newtown Seedling carried its foliage remarkably well. This is my sheet-anchor Strawberry. I have been occasionally deceived in other sorts as to a crop, but in this one never. That, however, is its best recommendation, but it is not devoid of usefulness. By its extreme firmness, high colour, and nice appearance it is the best I know for bottling; it is also useful for preserving, but rather too acid for dessert when there are so many others better. I have grown it for several years, and hope to grow it for several more; but the Vicomtesse stood the wet best, and preserved its foliage

dense and green all throughout, and then such a crop! and just as early as Black Prince, and five times better. It is good in size, good in colour, in taste not rich but refreshing, and is, according to my experience, the best early Strawberry extant; but this is a qualified verdict, as I have not quite grown all in the dictionary. If anyone thinks he can send me one earlier and better I shall be glad to have it, but as I am growing every day harder-headed, I shall attach this condition—that I prove it before I pay for it. I shall not have many come.

After the French peeress come the two next best, and best of all for general purposes and midseason. They are well named, too, in President and Sir Joseph Paxton. On stronger soil I have seen Garibaldi as good as either of them, but on this light ground the last must take a subordinate position in the Strawberry ranks. The longer I grow President the better I like it, and am certain it is the Strawberry for a non-strawberry soil. The crop is immense, and superior in this respect to Sir Joseph Paxton, but a trifle inferior in flavour, though not much. President requires more room than any other variety I grow. The rows should be quite 3 feet apart to allow its fine fruit bunches to spread and have air. Last year I had it less than 2½ feet distant, when the fruit of the rows overlapping and lying one on the other was one-half spoiled. I took out every alternate row, and this year have more than double the quantity of fruit from just half the number of rows, and I adduce that as the best argument for plenty of room. President has one advantage over most, if not all, others. After the first gathering of large ripe fruit, the smaller green ones continue to grow larger, and do not, as is common, lie still and ripen small. I do not mean to say that all the small ones get large, but they do this to a greater extent than any other variety.

After President comes that fine sort Dr. Hogg, but the little ones of this do not get big. The big ones, however, are fine indeed, alike in size and quality. It is not so hardy as those previously named, neither in frost nor wet-resisting qualities, but is, nevertheless, thoroughly recommendable. It will grow on lighter, poorer soil than British Queen, yet I will put the latter and Dr. Hogg together, and pay due and loyal respect to both.

Now for lates: and here Elton Seedling comes in, but not all alone in its glory. As a distinct sort Lato Prince of Wales, kindly sent me by Mr. Record, is fully as late, if not later, but I have only had it this season. It promises remarkably well, and bids fair to be really useful and worthy a place in a limited and select list. The few sorts named are what I have found to be the most useful, taking into account productiveness, quality, and succession. I observe they are nearly identical with a list recently recommended in the correspondence columns of this Journal, and I am sure may be planted with confidence. But this does not say there are not many other good kinds that I have not proved.

And now a word as to culture. This must vary according to soils, but in all cases planting early in July if possible; ground, however, is not always vacant at this

time. The most fruit from a given quantity of ground I have obtained this year has been from plants put in, just a foot apart all ways, on the 1st of August last year. As soon as fruiting is over, and in showery weather, half of these will be lifted and planted, and will again do well; but if the weather continue hot, they will be thrown away, and young plants again depended on. Another favourite plan of mine is at every 2½ feet, or 2½ by 3 feet, to put in three stout young plants in a triangle with a base of 6 inches. No one at next gathering-time can, without very careful examination, tell these from established two and three-year-old stools. In strong soils thorough deep-digging and making the ground rich to a depth of 15 to 18 inches, and a top-dressing of manure on the surface, will be all that is really necessary. If much deeper than this, and without surface-dressing, I have often observed the plants run too much to leaf. For fruit of all kinds there is nothing like surface roots, but they must be taken care of.

Strawberries like firm ground, and in a soil naturally light and warm I can get better crops by not digging at all, either at planting time or afterwards. I render acknowledgments to Mr. Radelyffe for this hint that I have put into practice. At desired distances scoop a hollow in the soil capable of holding two gallons of water. Soak this thoroughly with liquid manure, level-up, and put three plants in each spot. The manure water should be strong, and the hollow a foot in diameter. I have tried different sorts of manure, and find 2 ozs. of guano and 1 oz. of salt to the gallon the best of all, and better indeed than holes dug out 18 inches deep and filled-in and trodden with good manure. For a time the manured roots took the lead, but after two years the liquid-manured roots produced the most fruit, and best withstood the drought. It is the firm soil that does it. I always surface-dress my Strawberries in the autumn with half-rotted manure, or not quite half-rotted, and never take it off again. This may not be so necessary in districts with a heavy rainfall, but I know it is good practice here. Last autumn, considering the tremendous wet, I was for once doubtful as to the wisdom of the practice and only did a portion, but those dressed are much the best, and I decide that if it is good in a wet season it must be good in a dry one, at any rate where the soil is light. The winter's rains clean the manure perfectly, and leave a surface of smooth sweet straw, better packed than any hand could pack it, for the fruit to rest on. Where this top-dressing is not given, the best recipe to keep the fruit clean is Mr. Peach's—viz., straw cut into inch lengths. It is handy to apply and save when it is there, and is the best slug-antidote I know. I have watched the hungry "varmint" in their pilgrimage to the fruit, and am bound to say rejoiced in their treadmill-like work in turning over, and instead of the straw being the foundation for the slugs, the slugs were a foundation for the straw, and they were glad to get out of it. This would not have been the case had it not been cut into inch lengths.

It is important that clean surfacing be applied early, and it is the greatest possible mistake to defer it until the fruit is ripening. No one can possibly do the work then without more or less injury to the fruit-trusses. Strawberry trusses are as impatient of being disturbed as the haulm of young Peas, and neither can be meddled with without damage. Early surfacing has also another valuable point in its favour, in arresting evaporation and retaining the earth's moisture. It should be applied before the plants are in bloom, and it can never be done so well afterwards. A sprinkling of salt in early spring at the same time and in half the quantity of that given to Asparagus beds, or, to be more definite, about half an ounce to the square foot, is of much value, but more will not hurt if it be kept out of the crowns. By its deliquescent nature it keeps the ground moist and cool. It is certain to do good in dry localities to these things besides Strawberries. It should be applied previous to the straw surfacing. By salting and surface-dressing in autumn and early in spring I have had no occasion to water, although much hot and dry weather has prevailed. But—and this is important—I set aside two rows: one had no salt, and the other was not surfaced until the fruit changed colour; both these we have been compelled to water copiously, and then could not get the fruit so fine as the rest, but it was equally plentiful in point of numbers. Every point urged in this gossip is based on actual and careful practice.

I have never been sufficiently careful or curious as to note the relative value of the first or second roots of runners, but I do know that barren plants will produce barren progeny; I do not say invariably, but sufficiently so to make the practice

of planting from them an unsafe one. Just another hint: I cannot grow British Queen or Dr. Hogg by runners from my own plants, but if I have them from a thorough strong Strawberry soil I can get fair crops. I am certain this is a point of considerable value, and will in many gardens make all the difference between Strawberries and no Strawberries. Let those who grow this fruit under difficulties try, and I am very sanguine they will do as I do, "try again."—J. WRIGHT.

NEW ROSES.

MR. KEYNES did a good service to rosarians on the 16th inst., and he did it simply for their benefit, for he brought up from Salisbury seventy-two blooms of twenty-four of the best Roses of 1872. It was refreshing, after the dazzling repetition of Zonal Pelargoniums, to be able to take a chair and sit down comfortably opposite these fresh blooms and quietly examine them. It was a pleasant thing, too, after one had one's notes, to have them confirmed by two such authorities as Mr. Keynes and Mr. Turner: and therefore in giving my judgment, it may add some little weight to it when I say that it is thus confirmed. I have always maintained that it is utterly impossible to judge of the new Roses until the second year, they are only then recovering from the high pressure to which they have been subjected; but I do not recollect that we have ever had so good an opportunity of seeing the new Roses as on this occasion. We see some of them in the classes for new Roses, and oftentimes in the larger classes exhibited by nurserymen, but not in such a collection as this; and then they were so fresh, so fine, so, in fact, Salisbury-like, that it was a treat of no ordinary kind.

1. *Abbé Bramercel*.—A finely coloured, ill-shaped Rose. It may be tolerated in a stand, but will be, I think, more esteemed as a garden Rose. I should describe it as a cross between Eugène Appert and Géant des Batailles, having the intense colour of the former with the form of the latter.

2. *Bessie Johnson*.—This is a sport from Abel Grand, and is much lighter than that variety, and is worth adding to a collection.

3. *Etienne Levit*.—One of the best of the whole collection. The shape is beautiful, the petals large and shell-like, and the colour a fresh bright carmine.

4. *Madame Bellon*.—A pretty, well-shaped, light Rose.

5. *Madame de Parrieu*.—Bright rose shaded with carmine, but, then, said to be from Anna de Diesbach.

6. *Madame George Schwartz*.—Bright rosy pink, shading off into deep rose; fine form; a distinct and good Rose. I have always had a high opinion of this Rose, and am glad to see it confirmed.

7. *President Thiers*.—Fiery red; a fine colour, but wanting in quantity of petals. Probably will be grown for its bright colour, but not a first-class flower.

8. *Madame Scipion Cochet*.—Good form, but too thin.

9. *Louis Corbic*.—A pretty soft crimson rose. I find a Louis Charin in Messrs. Paul & Son's list; I do not know if this be the same.

10. *Baron de Bonstetten*.—Deep velvety blackish crimson. A grand Rose; quite in the way of Mons. Boncenne, but larger, and a good grower.

11. *Le Harre*.—Rough and thin.

12. *Souvenir de Général Douai*.—Bright salmon rose; large and full, and likely to be an effective Rose.

13. *François Michelin*.—A large, fine, and well-shaped imbricated Rose; silvery rose, with a fine petal. A first-rate Rose.

14. *Richard Wallace*.—Bright crimson rose; full, globular form, and attractive for its novelty.

15. *Madame Lefebvre Bernard*.—A splendid bright Rose; fine imbricated form, reminding one of Souvenir de la Reine d'Angleterre, but more refined and regular. A grand Rose.

16. *Madame de Riddar*.—Something of the colour of Beauty of Waltham. Good.

17. *Souvenir de Madame Hammet*.—Rough.

18. *Anaïs Rigoiard*.—Beautiful shell-like petals, cherry red. An excellent Rose.

19. *Princess Beatrice*.—Rough as shown here.

20. *Madame de St. Pulget*.—Shows the eye.

21. *André Duand*.—Light rose, with distinct paler edge; fine form, very beautiful in colour.

22. *Lyonnais*.—Light rose. Of the Charles Verdier type, but to my mind too watery in colour.

23. *Souvenir de Paul N. (Lea)*.—A very lovely flower,

salmon yellow edged with rose; large and full. Of the Madame Margottin style of flower.

24. *Bacante Louise Vrkull*.—Large and full; fine colour, but I am inclined to think uncertain.

25. *Souvenir de Charles Ferry*.—A seedling raised by our lamented friend, but hardly, I think, full enough to give it a lasting place.

I am inclined to give the first place to the following:—André Dunand, Etienne Levet, Madame George Schwartz, Madame Lefebvre Bernard, Baron de Bonstetten, François Michelin, and Souvenir de Paul Neron. In the second rank would come Abbé Brammerel, Bessie Johnson, Madame Bellon, President Thiers, Rigotard, Louis Corbie, Richard Wallace, and Souvenir de Général Douai. And it is odd to find that some of these, undoubtedly good, do not appear at all in two catalogues of our chief growers now before me, so completely is it a lottery which flowers are selected out of the eighty or ninety sent out. It will be a great boon if the new Cercle at Lyons exercise some sort of prohibitory power on the sending-out of such a multitude of new, and in many instances worthless flowers.—D., *Deal*.

G. F. WILSON PEA.

This proves to be a first-rate Pea, and fully justifies the Royal Horticultural Society in awarding it a first-class certificate. Those who like Vetch's Perfection should grow this variety; it is a decided improvement on that old favourite, being more prolific, having larger pods more equally filled, and is at least a week earlier; the colour when cocked is a lively green, and the flavour excellent. I shall grow it exclusively next year for my mid-season supply. It should be sown 2 inches apart in a single row, and the rows 8 or 9 feet apart, planting Potatoes or other low-growing vegetables between. Why do cooks spoil good Peas by boiling Mint with them?—WILLIAM TAYLOR, *Leighton*.

THE HYDRANGEA AS A DECORATIVE PLANT.

The common *Hydrangea hortensis* is perfectly hardy in the south of England, the Isle of Man, and other parts of the British dominions; but it is as a pot plant that we would here allude to its excellence.

Doubtless some of our readers may have seen the beautiful little plants of this species now being brought into Covent Garden Market by the London market-growers. These plants are propagated from cuttings in the autumn and spring, and flower in from twelve to fifteen months, bearing from one to four magnificent clusters of rosy flowers. Some of the largest, or autumn-struck plants, vary from 18 inches to 2 feet across, and are literally one mass of bloom, and invaluable either for window-plants or conservatory decoration. I visited a small market garden at South Acton the other day, and saw a long span-roofed greenhouse quite full of this beautiful plant, while hundreds had already found their way to Covent Garden before my visit. In the turf-pits outside, four thousand cuttings had been potted-off ready for next year's supply, and this in one small establishment only—a fact quite sufficient to show the high estimation in which this plant is held around London.

Old plants furnish quantities of fine cuttings, which strike freely in a moderate temperature, after which they are at once potted-off in good fibrous loam, leaf mould, and sand, and placed close together in any empty space at command. The leading growth is pinched out at the second or third joint, so as to obtain strong bushy plants as dwarf as possible. As the pots become filled with roots, they are again potted-on into 4's, and the larger ones into 32's, and in these they produce their flowers. During summer they are liberally supplied with water, a little manure water being occasionally added to strengthen their growth. They are kept as near to the glass as possible while growing, and fully exposed to the sun, by which means the plants are kept dwarf and bushy. The aim of the market-grower is to get these plants into the market as early as possible, since a much better price is thus obtained. Those now in the metropolitan market sell wholesale at from 21s. to 30s. per dozen, and are eagerly bought up at the price. The market-grower has, in fact, but little difficulty in disposing of his flowering plants or cut flowers, provided they are good in quality and early, these being the two great essentials necessary in order to succeed.

Everyone who has to keep up a succession of flowering plants in either greenhouse or conservatory, will find yearling

plants of the common *Hydrangea* invaluable for the purpose at this particular season, and for the next month or six weeks. We often see the *Hydrangea* with poor greenish blossoms; but if grown close to the glass in a low span-roof house or pit, fully exposed to sun and air, the flowers finish-off beautifully, and are of the brightest rosy hue imaginable. When growing, the plants require but little room, and when in full flower are very effective when grouped along with Fuchsias, Pelargoniums, Ferns, and other decorative plants.—P. W. B. (*in The Gardener*.)

METHOD OF GRAFTING RHODODENDRONS.

In his treatise on grafting Mr. Charles Baltet calls this method of grafting Rhododendrons "*Anglaise à cheval*," or, as we should say, "saddle-grafting." He describes it thus:—The stock B is cut wedge-shaped and sloping evenly, while the scion A is split up from the bottom, as at a, placed astride the

Saddle-grafting Rhododendrons.

stock, pushed over it, as at c, and tied up. Under glass clay-ine or waxing is unnecessary. Some years ago a charming collection of Rhododendrons was exhibited by M. Bertin, jun., in which a flowering shoot was employed as the scion, the result being in each case a truss of flowers. In this way it would be easy to have in a limited space a flowering collection of miniature Rhododendrons.

PEACH KERNELS POISONOUS.

It is not so generally known as it ought to be (says the *Argus*) that the kernels of some stone fruits, especially Peaches, contain prussic acid to an extent which may prove poisonous if a large number of the kernels be eaten. The following case, reported in the last number of the *Australian Medical Journal*, by Dr. W. R. G. Samuels, of Wanganui, New Zealand, should make parents cautious:—"February 19th, 1873. I was sent for to attend a little boy, aged five years, the son of a carpenter of this town. On my way I was informed that the little fellow had eaten something unknown to his parents, and was believed to have been poisoned. On my arrival, I found him lying on the sofa in a state of partial coma. The pupils were dilated, the skin somewhat cold and clammy, the pulse feeble. He seemed, in short, to be suffering from the effects of some narcotic poison. Upon making inquiries, I was informed that about half an hour previous to my arrival he had been seized with dizziness, stupor, fainting, inability to stand without

assistance—in fact, it was described to me as in partial intoxication. He vomited 1 oz. or more of masticated Peach kernels. I at once administered an emetic, followed shortly by a full dose of castor oil, which soon acted on the bowels. I ordered him to be kept warm. After being placed in bed, he slept for about two hours, after which he awoke and seemed recovered. This was obviously a case of poisoning by hydrocyanic acid (prussic acid) contained in the Peach kernels, of which the child had eaten a large quantity. My chief reason for reporting this is that I notice but one case mentioned in Taylor's 'Manual of Poisons' of poisoning by Peach kernels."

WALES AND WELSHMEN.—No. I.

I HAVE now been round Wales and through Wales, and am writing from its most beautiful sea-spot, truthfully named Beaumaris, built by Edward I. "upon a marsh ground, yet for the situation thereof he gave it this goodly faire name." But let not your readers deceive themselves with the expectation of finding in Wales any of the characteristics learned even in their nursery days. I have placed them long since on a blank page of Browne's "Vulgar Errors." Take first the national emblem—the Leek. "Common as Leeks in Wales" was a proverb centuries old, yet never have I, in garden or shop, seen a Leek in any part of the Principality. Who ever saw a Welshman with a Leek in his hat on St. David's day? I can aver it is not a popular table vegetable among them, but the "Welsh Onion" is; you see it everywhere, and this very morning I have seen baskets full of it at every greengrocer's in this capital of the Druids' Island as we have been long taught to consider it; but more about that presently.

We all have heard tell that Leeks are worn by Welshmen in commemoration of a victory they gained over the Anglo-Saxons in the sixth century, and which they attributed to wearing Leeks, by the command of St. David, to distinguish themselves in the battle; but others say it is because each of the small farmers who aided each other with ploughs brought Leeks to the common repast. And this I hold as more probable, sustained as it is by the still general practice of the Welsh Onion being the usual accompaniment of the bread and cheese you see vanishing from before every farm labourer as he rests beneath the field hedge; and a tradesman replied to my observation, "It's relishing, yet satisfying," which curiously agrees with old Tusser's verse:—

"In March Leekes are in season for pottage full good,
And spareth the milke cow, and purgeth the blood,
These having with peason, for pottage in Lent,
Thou spareth both omelet and bread to be spent."

Now, about this island of Anglesea, and its being especially the stronghold of the Druids. Camden says, "This isle was called of the Romans *Mon*, of the Britons *Mon* and *Tir-Mon*—that is, The land of Mon; and *Ynis Dowil*—that is, A shadowy or darke island; of the ancient Anglo-Saxons *Monez*, and at last after that the Englishmen became lords of it, *Engles ea* and *Anglesey*, as one would say, The Englishmen's Island. (Not a word about the Druids in those names.)

Giraldus Cambrensis states it was so fertile and so productive of Wheat that there was a local saying, *Mon mam Cynbry*, or "Mon is the mother of Wales." This saying is as old as 1188, for it is recorded then by Archbishop Baldwin in his "Itinerary through Wales," and it is stated that it was so called because its superabundant crops supplied the other parts of the Principality. If this were so, those other parts must have been superlatively unproductive, and Anglesea must have been more fertile than at present, for the soil is poor and the crops very inferior, Potatoes excepted, and they were unknown in Baldwin's days.

Mentioning Potatoes reminds me that I gladly learned in Oxfordshire, Cheshire, and now in Anglesea, that the disease this year has not made its appearance.

But to return to the theme from which I have diverged. Was Anglesea the stronghold of the Druids? I cannot conceive that such was the fact. There are no woods, no fossil remains of forests, no soils in which forests could have flourished, yet woods were their homes; and their sacred plant, the Mistletoe, does not grow here, and will not live here. I will jot down some of my notes about this plant, and let any one of your readers judge whether an island where the Mistletoe never dwells is likely to have been the Druids' home.

The Mistletoe is a cosmopolitan parasite, for it has been found not only on the Apple, but on the Horse Chestnut, Maple, Poplar, Acacia, Laburnum, Pear, Sallow, Locust, Larch,

Scotch Fir, Spruce Fir, Service, Hornbeam, Olive, Vine, Walnut, Plum, Laurel, Medlar, Oak, Cedar, Hazel, Ash, Lime, Elm, Baelthorn, Whitethorn, and Birch; therefore it is not the absence of a suitable tree that excludes it from Anglesea. But it is more particular as to the climate it will put up with. It flourished for a time in the Botanic Gardens at Dublin, but it died, and Dr. Moore, the Curator, repeatedly, but unsuccessfully, tried to re-establish it; yet at Farmley, in the county of Kilkenny, it has immemorably lived on the Apple trees. At Badamscourt, near Chepstow, for three-fourths of a century it was on an Oak; yet in another district of Wales, Peniarth, Merionethshire, and in other places, Mr. Cooke, gardener there, says the Mistletoe is almost unknown. That it does not grow in Anglesea is testified not only by the replies to my numerous relative inquiries, but by Mr. Hugh Davies, a native of the island, and who published a volume on its native plants. His is a remarkable testimony, for he was unwilling to admit the fact, and he says, "I have not seen this plant; but we can scarcely suppose that the Druids had fixed upon, as a favourite residence, a spot that did not produce this highly-venerated plant." The assumption rather is that they did not reside here because of that non-production.

Some have considered—I am alluding to Welshmen—that *Uchelawg*, the Mistletoe, is a magical herb, probably the Forbidden Tree in the middle of Eden's trees, for in the Edda, to the Mistletoe is ascribed Balder's death, caused through listening to a woman. The Druids had a great veneration for the number 3, and Vallancey says "the Mistletoe was sacred to them because not only its berries but its leaves grow in clusters of three."

In Brittany, at Yule-tide, the Druids sought for a Mistletoe on the Oak of about thirty years' growth, and when found it was consecrated, the *Panchrestum*, or universal remedy—the restorer of health and the securer of happiness. It was cut with a golden, or more probably brazen, sickle, and after a sacrifice and prayer, fragments were distributed to the prostrate people. Whoever obtained a fragment believed that he was sheltered from sickness, witchery, evil spirits, and even thunder-bolts.

As the berries of the Mistletoe were considered promoters of fertility, and the whole plant to be all-powerful to preserve from evil, kissing beneath it may well have been practised as an invocation to obtain those benefits; and it is certain that a belief prevailed that the maiden not kissed under the Mistletoe would not be married next year. We may be quite certain that Shakespeare calls it "the baleful Mistletoe" because it is injurious to the trees on which it prevails, and not because he objected to kissing beneath it.

At Christmas, or Yule-tide, the Druids laid the Mistletoe, which they called "All-heal," on their altars. This they cut off the Mistletoe from the trees with brazen celts, or hatchets, fixed on the ends of long staves; and, in Stukeley's time, on Christmas-eve Mistletoe was placed on the altar of York Cathedral, and a general pardon was proclaimed at the gates of the city.

Selden relates that in France about Christmas-tide the young men went from village to village knocking at all the doors, with the exclamation, "*An gwy l'an neuf*"—that is, "To the Mistletoe this New Year;" the Celtic name of the Oak was *gwy*. This seems to be a relic of Druidical customs; for it is recorded that at Christmas time the Druids in solemn procession went to gather the Mistletoe on the Oak, chanting as they went, "The New Year is at hand, gather the Mistletoe."

In Gay's time the Mistletoe was mingled with other evergreens in decorating our churches, for he wrote—

"Now with bright *Holly* all the temples strow,
With *Laurel* green, and sacred *Mistletoe*."

Even now in Worcestershire a farmer will give the Mistletoe bough in his house to his cow that calves first after New Year's-day to secure luck to all his dairy. But the belief in the general curative as well as the mystical powers of the plant's berries still prevails in many places, and as the plant was widely known here as "All-heal," so was it known to the ancient Romans by the synonymous name of "*Omnia sanans*."—G.

P.S.—I hope this will be in time to qualify that which I wrote about the Mistletoe in Anglesea. I can meet with no one who has seen it growing naturally here, but I have seen it flourishing in the garden of a butcher named Hughes. He has a very luxuriant and fruitful orchard, and on the bark of

some of the Apple trees, fourteen years since, he placed Mistletoe seeds which he brought from Denbighshire. The seed germinated, and the plants not only are vigorous, but offsets from them have come forth lower down the branches on which they are growing. So the Mistletoe will not only grow but endure here.

ARRANGEMENT OF A FRUIT GARDEN.

The accompanying engraving represents a section of the fruit garden of the "Jardin d'Arboriculture," in the Bois de Vincennes, at Paris; and it conveys a very correct idea of the arrangement of fruit trees which are cultivated for profit; the produce of fruit being sold for the benefit of the establishment. The estimate which the authorities made of the value of the probable crop was to be in 1874, 10,000 to 12,000 francs. It remains to be seen whether this will be realised.

The plan of the garden is excellent, and although this part of it which we now figure is entirely occupied with Peach trees, the same arrangement may be adapted to different varieties of fruits if the plan is used in this country. The wall which forms the background may be covered with single cordon Peaches, Nectarines, and Apricots, or, if preferred, the trees may be trained fan-shaped. Then the tall, coped trellises might be occupied with Pears and Plums, while the dwarf wired borders, or "man-traps," as they have been called, might be appropriated to the finer varieties of Apples on Paradise stocks. We have often seen in the gardens of the bourgeoisie about Paris trees grown on a somewhat similar arrangement with great success.

Our engraving is from M. Alphan's splendid work, "Les Promenades de Paris."

PLUCK THE FLOWERS!—All lovers of flowers must remember that one blossom allowed to mature or "go to seed" injures the plant more than a dozen buds. Cut your flowers then, all of them, before they begin to fade. Adorn your room with them; put them on your tables; send bouquets to your friends who have no flowers, or exchange favours with those who have. All Roses after they have ceased to bloom should be cut back, that the strength of the root may go to forming new roots for next year. On bushes not a seed should be allowed to mature. —(Scribner's *Morning*.)

SCUTELLARIAS.

I would fain draw the attention of plant-growers to the special claims which this beautiful genus of Labiates has upon their attention. More especially do these remarks apply to amateur gardeners with but limited stove accommodation. True, they cannot be grown into large specimens for exhibition purposes; but everyone does not grow for exhibition, and a genus of plants that will produce quantities of bright and gay-coloured flowers in quite a small state are well deserving of attention. Scutellarias are amongst the most easily grown plants of any that I

know; they are mostly herbaceous or small shrubby-growing plants, which bear cutting well and bloom throughout the greater part of the year. They may be grown in small pots. The compost which suits them best is loam, peat, leaf mould, and sand in about equal parts, and in a cool stove they will grow admirably.

These plants produce their flowers very freely. They are admirably adapted for cutting for bouquet-making, and also for placing in vases with Fern fronds, Grasses, &c., for the decoration of the drawing-room or dinner table. They are rather apt to become bare of leaves towards the bottom of the stems, and are thus much benefited by frequent cutting. Moreover, it conduces to production in succession; and if some few species are grown, the cultivator will not lack bloom the whole season round. Having thus made out a good case in favour of Sentellarias, I shall now enumerate a few of the best species for anyone to cultivate in order to arrive at the desired results.

S. rotundifolia.—A tall-growing species of great beauty. The leaves are ovate-lanceolate, slightly serrate at the edges, and rich dark green. The racemes of bloom are terminal, and are nearly 3 inches long; the individual flowers are tubular and stand erect, forming a splendid dense head; the tube is rich crimson, whilst the open mouth is orange yellow. As I have before remarked, these flowers are beautiful objects for placing in vases, &c.; and as the plants are cut back this causes lateral growth, so that a succession of its rich blooms may be obtained throughout the year. Native of Costa Rica.

S. aurata.—This is a fine plant, and quite distinct from the last-named. The leaves are oblong-ovate at the base, clothed with fine hairs and bright green. The terminal racemes of flower are yellow, with the inside of the lips rich orange. It is as free-flowering as the previously-named kind. Native of Mexico.

S. incarnata.—A compact neat-growing species, having cordate dark green leaves, which are slightly serrate at the edges and hirsute on the lower surface. The terminal racemes of bloom are very dense, and the flowers are deep rose colour, affording a pleasing contrast to the before-mentioned kinds. Native of Brazil.

S. incarnata Trima.—This variety may be distinguished from the normal type by its leaves being somewhat smaller and quite destitute of hairs. The flowers differ also in being rich red flesh-coloured. Native of New Grenada.

S. Mociniana.—A fine and large-flowered species, the leaves of which are ovate-acuminate, hairy on the upper side, and dark green. The racemes of blooms are very large, the individual flowers being upwards of 2 inches long; the tube bright orange scarlet, and the throat deep yellow. Native of Mexico.

S. Pentanatif.—This is a charming free-flowering plant; leaves ovate, tapering to a point, and deep green. The flowers are nearly 1½ inch long and brilliant reddish-scarlet. It might be termed a continual bloomer. Native of Brazil.—FALLENB. CREDE.

ON THE URARI,

THE DEADLY ARROW-POISON OF THE INDIAN TRIBES IN BRITISH GUIANA.

[Read by Dr. R. Schomburgk before the Adelaide Philosophical Society, on April 19th, 1866.]

The great and unfortunate Walter Raleigh was the first who brought to Europe an exact information of the existence of the dreadful and quickly-operating extract called "Urari," which was used by the natives on the Orinoco and Rio Negro for the purpose of poisoning their arrows used in war and for hunting. Though a great deal of attention has been paid, since this information was first received, to distinguish the true from the untrue in the mysterious accounts which were circulated concerning the ingredients used for the preparation of the "Urari," yet it was without success, even up to late years. The accounts of older travellers and missionaries, like Hartwick, Gumilla, Gill, and others, outbid one another in the fabulous and mysterious. The former related that, to try the strength and quick operation of the urari, the Indians send their arrows dipped in urari into a young tree. Does the tree die in the space of three days, the poison has the required strength. Other fabulous accounts need not be mentioned. In the beginning of the nineteenth century it was Alexander von Humboldt who gave us the first authentic accounts concerning the preparation of this dreadful poison, having been present at the manufacture of the same in Esmeralda, on the Upper Orinoco. Later travellers were dissatisfied with the simple process as stated by

Humboldt, and tried again to give the preparation of the urari a more mysterious appearance. It was maintained that the vegetable extract was only the medium of the deadly poison, and that the urari only received its life-destroying power through the addition of the fangs of the most poisonous snakes, poisonous ants, and Cayenne pepper. None of these travellers had been present at the preparation of the urari, and none of course had seen the ingredients added to it. These accounts are only supported by the communications received from the Indians, whose interest it is to represent the preparations to be as difficult as possible.

To test the respective value of these different accounts, my late brother, Sir Robert Schomburgk, felt induced, on his first expedition to the interior of British Guiana, to give this subject his closest attention. Already, on the Upper Rupununi, he was so fortunate as to see one part of his wish fulfilled in getting at least a botanical knowledge of the dangerous plant which gives the main ingredient for the preparation of the urari. In the Wapishana settlement, Aripai, on the Rupununi, in 3° north latitude, he was informed that the plant was found growing in the Canuku Mountains, distant about one and a half day's journey from Aripai. Accompanied by some Indians he went to the place. After a wearisome march they reached the mountains near Mamesua, a Wapishana settlement, where they stayed all night, and where to his great joy he found an inhabitant who not only was well acquainted with the place where the plant grew, but who also understood the preparation of the urari. He was quite willing to bring him bark and branches of the plant in any quantity, but refused to bring my brother to the place where the plant was growing. Only rich presents would at last induce him to act as a guide. The next morning they set out, and after great difficulties, the road winding through a very stony country, they discovered the first plant. Although this neither showed flower nor fruit, my brother recognised in it a new species of *Strychnos* (which he named *Strychnos toxifera*). No persuasion would induce the Indian to prepare the urari in the presence of my brother. During the second expedition of my brother up the Essequibo, he had an opportunity to visit the regions of the Urari plant. During his stay in Pirara, a Maensi settlement, lat. 3° 33' N., long. 59° 16' W., he was informed that near the Canuku Mountains a Maensi Indian was living, who was known as the most renowned preparer of the urari in the whole tribe. He inquired after him, and he was successful in persuading him to prepare the poison in his presence. In the company of the poison-preparer he made first an excursion to the western part of the Canuku Mountains, where it was said the plant was also in existence, not only to get from there the material to prepare the deadly extract, but also to try whether he could see the plant in flower. The Flaunkipang was about eighteen miles in a south-easterly direction from the place he was staying at. Under the same difficulties which I experienced afterwards, they reached the first plants; and although he found them without flowers, he saw the fruit, which confirmed his supposition of its being a *Strychnos*. After collecting some of the necessary bark of the Urari plant, only taken from such plants as were in full sap, they returned to Pirara.

The preparation of the poison was delayed for some days, as the preparer of urari stated that to enable him to produce the poison he had to subject himself to a strict fasting. During that time a notorious chief, named Kanaima, from the Rupununi, arrived in Pirara, who persuaded the preparer of the urari to withdraw his promise to prepare the poison in the presence of my brother. The Indian with great energy asked my brother to return the bark of the *Strychnos*, to which request my brother of course did not accede, taking the urari bark to Fort San Joaquin, a Brazilian fort on the River Rio Branco, which place the expedition exchanged with their former abode in Pirara. Here my brother undertook to make an experiment himself to extract the poison from the bark of *Strychnos toxifera* alone. For that purpose he took 2 lbs. of bark, which he pounded, put it into a pot, adding to it a gallon of water. He let this remain twenty hours, putting the half of the extract—which already had assumed a brown colour—into another pot, boiling it over a slow fire until it took the consistence of treacle, and during this process the remaining extract was added. Two fowls were wounded and the poison inserted—one in the foot, the other in the neck. The effect of the poison appeared after the lapse of five minutes; yet the second—wounded in the neck—died in twenty-seven minutes, the other in the twenty-eighth after the wounding. This was a sure proof that the *Strychnos toxifera* alone, and without the admixture of other

ingredients, develops the deadly properties, and that all other additions are not essential to the strength of the urari. The boiling-down of the poison was finished in seven hours, while it takes the Indians more than forty-eight hours, which accounts for the slower effect the poison took which was prepared by my brother; the continued boiling, of course, concentrating the extract. The colour of my brother's extract was a light-brown, while that of the Macusi Indians was almost pitch-black, probably from the admixture of the other ingredients.

This vegetable poison is known by several tribes of the Indians between the Amazon River and the Orinoco; yet almost every tribe differs not only in the preparation of the same, but also in the ingredients used. This manifold preparation is also the cause that with almost every tribe engaged in the preparation of the urari, the strength and time in which the poison operates are different. I have already observed that the existence of the most vigorous plants of the *Strychnos toxifera* is limited to some localities within the ground which is inhabited by the Macusi Indians, and that may also be the cause why these are generally considered everywhere the preparers of the strongest poison. The arrow-poison of the tribes on the Amazon, Rio Negro, and Orinoco, which came into our possession through chance, only operates after the lapse of three to seven hours; that of the Macusi produced the death-struggles in as many minutes. This renowned strength of the urari of the Macusi Indians brings whole caravans of Indians from the Rio Negro, Orinoco, and even from the Amazon River to the Canuku Mountains, to exchange the urari with the inhabitants for other articles. Von Martius gives us an account of the preparation of poison of the tribes of Juris, Passos, Tecunas, and others on the Amazon and Yupura. The traveller Poeppig gives a description of the vegetable poison in Peru and Chili, and Humboldt of the same as prepared in Esmeralda, on the Orinoco. Every one of these tribes use, according to the accounts, quite different ingredients. My brother, on a visit to the mission of Esmeralda—lat. 3° 11' N., long. 66° 3' W.—which was so flourishing when Humboldt was there—found only one family remaining. The old patriarch told him that he had exchanged his arrow-poison with Iodiani tribes inhabiting the territory near the Rivers Parana and Ventuari, especially from the Guinaus and Madongkongs. Both tribes which had been visited by my brother call the arrow-poison "Cumarawa" and "Makari;" but even these tribes prefer the urari prepared by the Macusi to their own, the latter effecting the quickest operation.

(To be continued.)

THE SPURIOUS MAY DUKE CHERRY.

It is a wonder to me that this deformed worthless Cherry has not been the subject of a note from some of your leading writers long since. It seems to me to be on the increase of late, to such an extent indeed as to call for instant measures being taken to put a stop to its further propagation. Just now being the time for budding, I think it worth while to call attention to it; but I much deplore not being in a position to offer a positive guide, to enable a person about to bud to be certain whether he is working the right or wrong without the fruit being present. Whether it is a sport I know not, but the fact that it is increasing is too apparent, and when planted for a real May Duke it is disappointing indeed. On a person going to a nursery to purchase a tree, should there be this bastard amongst them it will sure to be the first to attract the attention of the buyer as being a "healthy promising tree." We planted two supposed May Dukes with other Cherries a few years since; one, the true variety, has produced crops for the last three seasons, the other just a sprinkling, ripening, if at all, about a fortnight later than the true variety. I say, if at all, for it often occurs that but half of the fruit do so, the other half remaining quite green or yellow; and then to eat them is simply impossible, so acid and bitter are they. Bear in mind, I am not making a mistake, it is not any of the later Dukes. I have often found, especially in bush trees, a single branch, or two or three, even half or more of a tree, bad, while the other part has been good, and *vice versa*, but I always fancied the good to be somewhat more acid than from trees that were wholly good.

Now, there is one thing I am confident of—viz., it being

The article of exchange which the Macusi take are the celebrated and dangerous Wapipi, which are made out of a small cone shaped *Arum* (*Arundinaria Schumacheriana*), which is found on the river Parana; it grows to an enormous height, and the joints or buds appear at a distance of 16 to 15 feet apart.

much the stronger grower, the budder will naturally take its shoots before those of a weaker one for his buds; hence this variety being now so prevalent. There is this again—the buds are generally taken in nurseries from young trees, and, fruit being absent, there is nothing to show whether one is working good or bad stock. Selecting the strongest shoots year after year has been the means of substituting for the good, moderate-growing May Duke, a worthless fruit no better than the wild Cherry of our woods. The end will be, if not at once looked to, that we shall not be able to purchase a good May Duke. The only remedy seems to be that buds should only be taken from old trees that are known to be good. I well remember helping to plant a plantation of young trees of May Dukes in my father's garden, many of which turned out to be quite worthless in this way; but I believe, if I recollect rightly, he was of opinion that they would eventually come good, but I am not in a position to say if he realised his hope. It would be interesting to know if any of your correspondents are able to verify this expectation.—J. TAYLOR, *Maesgwynne, South Wales.*

We have ourselves known nursery stock of *Bigarreaus* being very much mixed through scions being taken from a strong-growing wilding on which the bud had failed, and which had been left to grow as if it had been a budded plant. Nurserymen cannot be too careful in this respect.—Eds. J. or H.]

GAZANIA SPLENDENS OR RIGENS.

WHATEVER disadvantages may attend a dull, cold, and late spring, there are certain plants which are benefited by a mild winter. On all sides we hear of *Calceolarias* standing uninjured, and a friend of mine in the west of England informs me that a Scarlet Geranium in a rustic vase fully exposed has stood the cold and is now in full flower. Such, however, was not the case in the majority of places, for the wet killed the plants where the frost was not sufficiently severe to cause that result; nevertheless, many plants passed through the last winter with little injury. A number of New Zealand *Veronicas* growing here against a low wall, and which we have slightly protected in most winters, have survived without any such covering and are flowering freely, while the plants are robust and healthy. Other plants of the same kind fully exposed were also uninjured, but later in blooming.

My purpose now, however, is to call attention to a plant which with some has been a great favourite in the parterre, while it has been unduly condemned by others. Those who want early bloom have, in general, just reason to complain of it, but for a late display it is all that could be desired. In the present season we had it in all its beauty early in June, and there were flowers out in May, notwithstanding the lateness of the season. The plant referred to is *Gazania rigens* or *splendens*, which is much more easily managed than many suppose, as it is nearly as hardy as the *Calceolaria*, and not subject to the sudden and unexpected dying-off to which that once-popular plant is liable in so many places. On a gravelled terrace here we have a number of small beds raised about 10 inches by rustic woodwork, and to overhang this woodwork we usually plant some suitable trailing plant; last year *Gazania rigens* was employed on four of the beds, and succeeded as well as usual during the summer and early autumn months. As the latter were mild and wet, and the *Gazania* did not show any signs of injury from the cold, it was allowed to remain, and is now one of the gayest plants. The healthy green foliage is studded with star-like blossoms of bright orange, and only two or three plants in one of the beds have failed. This, of course, is an exceptional case, and winters which this plant will survive unscathed do not occur more than once in five or six years; still it is possible that near the coast it may do so more frequently than inland, and where it does so it is of great beauty, and well deserves all that has been said in its favour.

There are other places than the flower bed where it may be tuned to account. The rockery would seem to be a more fitting place for it than the flower bed, because its failure on the mixed rockwork would not be of so much consequence as when a broken edging of a flower bed had to be repaired by plants of a smaller kind. Moreover, I think the rockery is a more likely place for it to escape injury, for it will probably be drier than a flower bed. In the case of our plants that safely passed through the long wet winter of 1872, they were growing on a raised bed on dry ground, and the bulk of the tops hung over the side; and as the frost was at no time suffi-

ciently severe to destroy the stems of the paler-sepaled Fuchsias growing in the same bed, it may be inferred that dryness and elevation had a considerable influence in the matter. *Centaurea candidissima* has stood many years in a similar position, withstanding rather severe winters. Those who have plants of this *Gazania* occupying dry sheltered position ought not to be in any hurry to remove them in autumn, for they may prove useful at a time when bedding plants, so called, are far from plentiful.—J. ROBSON.

NOTES AND GLEANINGS.

WE are informed that MR. PEARSON, of CHILWELL, was so gratified by the display of GERANIUMS which was made at the last meeting at South Kensington, in competition for the prizes he offered, that he has decided to offer a similar set of prizes next year.

— It is announced that the MANCHESTER INTERNATIONAL HORTICULTURAL EXHIBITION, to be held in September, will be opened by the Earl of Derby on the 3rd of that month, and that he will also take the chair at the dinner in the City Hall.

— MESSRS. J. WEEKS & Co. have just issued an ILLUSTRATED BOOK OF DESIGNS FOR HORTICULTURAL BUILDINGS, in a very tasteful style. These designs are in chromo-lithography, and are shown in connection with the dwelling houses to which they are to be attached. Besides the chromo-lithographs, there are numerous other lithographic illustrations of every imaginable form of glass structures.

TACSONIA MANICATA (GAUNTLETED TACSONIA).

THE Passionworts comprise some of the most gorgeous of tropical climbers, but there are few, even of the tender species, which surpass or equal in beauty this magnificent plant. Although it is brought to us from equatorial regions, yet, from the altitude at which it is found growing (often 7000 feet above the level of the sea), it is a greenhouse climber.

In their habit of growth the *Tacsonias* resemble very closely the common Passion-flowers, being, like most of them, of vigorous growth, the shoots extending 10 or 20 feet in a season, according to the age of the plant. The resemblance between the two genera is indeed carried so far, that some of the most acute botanists of the present day are unable to give the precise grounds for the separation of the *Tacsonias* from the true Passion-flowers.

This leads us to the botanical structure of the plants of this order, which is too remarkable to allow of being passed over; and as the *Tacsonias* possess its chief characteristics, our illustration will serve as the text of our remarks. The climbing stems (which are somewhat rounded, and not four-sided, as in *T. pinnatistipula*), and three-lobed foliage, do not claim any special notice, unless it be to point out the glands on the upper edge of the leafstalks, and which are found in most Passion-flowers. Occasionally they are placed at the base of the leaf, near its junction with the petiole, and sometimes on the back of the leaf. These glands, although not conspicuous, are easily perceptible to the naked eye, and have the appearance of small greenish yellow projections rough to the touch. The stipules, or small wing-like expansions at the foot of the leafstalk, are another peculiarity of the true Passion-flowers. In *T. pinnatistipula* they are deeply divided, as the specific name implies; and in *T. manicata* they are toothed in a crested manner.

The chief interest of the plants of this order, however, centres in their elegant flowers. These are, at a glance, seen to consist of ten segments or divisions, the lower portions of which are united into a tube, surrounded at its base by three leaf-like bodies termed bracts. These bracts, which are shown in the engraving, are common not only to the *Tacsonias*, but also to nearly all the other Passion-flowers, though in a few species they are placed at a considerable distance below the flower, and are extremely small. In one or two species they are cut into hair-like segments, and give a very interesting appearance to the flower, as in the *P. ciliata* and *P. foetida*. These bracts are not much larger in *T. manicata* than in many other Passionworts; but from the shortness of the tube, which is almost concealed when the flower is expanded, "it may not unprofitably be compared to an arm thrust into a large loose glove;" from which circumstance it is presumed that Jussieu gave it its specific name of *manicata*, or gauntletted.

Some difference of opinion exists with regard to the real

nature of the coloured portions of the flower. Lindley considers the five outer segments to be the true calyx, and the five inner ones as the corolla; whilst others look on the filaments, or ray-like appendages, as the true petals, and consider all the segments as sepals. Each segment of the outer series is terminated by a horn-like process, which is, in fact, a prolongation of the keel-like ridge on the back of the sepals. The inner segments, which we will call the petals, are rather broader and more rounded at their ends.

Tacsonia manicata.

The remarkable appendages arising from the base of the petal, and which are termed the rays or crown, vary exceedingly in the different species. In the *Tacsonia manicata* they are very short and tooth-like, and are arranged in two concentric series; but in some of the Passion-flowers these filaments are nearly as long as the divisions of the corolla, and are grouped in four or five rings, the innermost series being generally much the shortest. They are regarded as modifications of the petals, between which and the stamens they are probably intermediate in their nature. The stamens are monadelphous—that is, the stalks supporting the anthers are united into a tube, above which is borne the ovary seated on a long stalk, which passes to the bottom of the calyx-tube. Both the anthers and stigmas are unusually large, and the pollen or farina from the former forms one of the most interesting microscopic objects that can well be imagined. Each grain of pollen appears, when viewed under a rather high power, as a spherical body covered with a delicate network, and bursting by opercula, or lids, of which there appear to be four, to allow of the protrusion of the pollen-tubes. The fruit is not the least remarkable part of the plant. In *Tacsonia pinnatistipula* it is 5 or 6 inches in circumference, spherical, and when ripe of a yellow tint, hanging by the very long peduncle to which the remains of the flower are usually attached. The seeds are surrounded with a pulpy arillus of an edible nature, especially in a few species, which are not unfrequently cultivated for the sake of their fruit, as *P. edulis* and *P. quadrangularis*.

T. manicata may be increased by cuttings either of the old wood in spring or of short young shoots in summer, under a bell-glass with a little bottom heat. When grown under glass most of the *Tacsonias* will ripen seed, from which they may be readily increased.

The specific name has been already explained; the name of the genus appears to be a latinised form of *Tacso*, that by

which the plants are known in Peru. There are several species besides *T. manicata*, those best known being *mollissima*, *pinnatifidula*, *princeps*, and *grandis*.

We must not omit to observe that the shoots of the *Tacsonias* do not require shortening, but if they are too crowded they may be thinned-out while young. When the growth is too rampant and sterile of blossoms, a flowering habit may often be induced by training the shoots horizontally, or nearly so.—W. THOMPSON, *Ipswich*.—(*English Flower Garden, Revised*.)

SOILS. THEIR VARIETY AND USES IN VEGETATION.

THESE IS, perhaps, no term that conveys to the minds of readers the idea of a greater diversity of substances than the word "soil." I will not enter into these, but at the outset state my intention to confine the remarks made to that outer covering of the earth which supports vegetation, and plays so important a part in the welfare alike of the animal as of the vegetable world. It is the part it plays in supporting vegetation, and the diversities it presents in the different localities in which it is found, to which I shall direct attention in the following remarks.

Praiseworthy as undoubtedly is the industry of individuals or of communities who have by diligent and well-directed cultivation rendered a piece or tract of land highly fertile that was previously almost sterile, there can be no question but there are tracts where Nature in a long course of years has accumulated an amount of vegetable wealth which it is not easy by artificial means to store-up. A course of yearly manurings will render a piece of indifferent land fruitful, but it is made so by the addition it yearly receives, and if left to itself there is reason to believe it would relapse, certainly not into exactly the condition in which it was originally, but into one somewhat approaching it, if left unaided for a sufficient length of time. Most likely the additions it received while in cultivation would have their influence for a number of years; and if the superfluous water had been drained away in something like a permanent manner, there is little doubt that the surface soil would have undergone a change, both chemically and mechanically, so that it would not easily revert into the old condition; while if cultivation were continued instead of left off, the piece of poor unfertile land might in time become the reverse of what it once was by the aid of liberal dressings of substances foreign to its original composition. In this, in a great measure, lies the art of good cultivation, and we have not to go far in most neighbourhoods to see examples of it. At the same time it must be confessed that now and then cases are met with where labour and material also may be said to be thrown away; and even in gardening I do not think we are always in the right in what we do or advise in the matter of soils and their treatment. But before embarking in a condemnation of a system that is recommended by so many in almost every number of "our Journal," and often more than once in the same paper, it will be as well to make some further remarks on the character of the various soils the garden-er has to deal with, and also of those auxiliaries to them that he may have at command, but of course in a smaller way.

Taking, therefore, the character of the soil of a given district into consideration, we shall find on examining it that there is often, but not always, considerable diversity in samples that may be taken from spots not far apart, more especially in hilly districts. The crown of the hill may have only a thin skin or covering of soil bound together by a hard wiry kind of grass or other herbage, while at the base of that hill, perhaps not a stone's throw off, may be a morass with several feet deep of black vegetable matter that has been accumulating for countless ages, and is still increasing, unless disturbed by cultivation. Acting as a sponge, it sucks up a great part of the water the hill is charged with, and remains a bog that would not be passable by either man or animals in all places were it not for the thickly-woven carpet of turf or other herbage which forms its outer covering. Such places are becoming fewer as cultivation extends; for by draining off the water from the level alluded to, and subjecting the surface to cultivation, by degrees it is made to support plants widely different from those natural to such soils. It is some time before the change finally does take place, but by skilful treatment and adapting the ground first to the growth of such plants as it is most suitable to, it is by degrees brought not only to support vegetation of another kind, but to enable that vegetation to flourish

in more or less luxuriance. The accumulated substances in which it is so rich are not so easily exhausted as a soil not previously so well fed, and hence its staying powers. At the same time let it be fully understood that such a soil is one not usually converted to garden purposes, although I have more than once seen orchards of several acres in extent do pretty well on such a soil, kept moderately dry by deep open ditches from 12 to 20 feet apart. One was a peaty swamp to which salt water must have had access, and probably left a seasoning behind it more favourable to the growth of *Planes*, &c., than such soils usually are where the morass is not so formed.

Taking another class of soil, and one occupying a position in a valley like the last, but not usually so level, we find the material to which the term soil is usually applied a combination of matters in which stones, from the size of a cricket-ball to that of a bean, form three-fourths of the whole, and these stones are all rounded like the pebbles on the seashore. An intermixture of a little fine matter gives such ground a certain degree of fertility, but the inert character of the stones deprives it of the right to be accounted a good soil, and a hungry gravel is the name often given it, and with good reason too, as it is often an ungrateful soil to the husbandman, and one which he dislikes more or less according to the proportion of stones which compose it. But a moderate quantity is not only harmless but really useful, permitting the atmosphere to penetrate the earth by their always remaining the same size; whereas the swelling and contracting of the material surrounding them enables the air to penetrate in the latter condition. A certain amount of gravel is beneficial to most soils; for although it can scarcely be said that a hard piece of flint in the form of an egg can impart nourishment to a plant, it nevertheless forms a sort of nucleus around which the roots of plants may cling and obtain the food supplied them by the soil which surrounds them; and stones on the surface help materially to keep in moisture during hot summers, and consequently induce the formation of roots near the surface, where they would not be without some such covering. Thus we must not altogether despise the gravelly or stony soils we often meet with, unless it happen that these gravels are too hot, and, maybe, rest on a sort of pernicious subsoil, alike obstructive to vegetation and to the tools of the cultivator. But extreme cases of this kind are not common, while ordinary gravelly soils are met with in many places.

We now come to the soil overlying the chalk or found at its base, a soil much more productive than to the ordinary observer it appears to be. Containing, as it does, so much calcareous matter, it at once points out the class of plants it is adapted for and the contrary kind. Strange to say, although chalk in itself is destitute of water, or nearly so, the soil or coating by which it is often so thinly concealed from the open air is far from being light, open, and porous; and we not unusually meet with a stiff clay or stiff loam at the base of chalk hills, where the chalk itself does not embody sufficient flinty matter to render it otherwise. Chalk is usually met with in hills and often to a great depth; but in some neighbourhoods, as in Hertfordshire, it often descends into the valleys, the soil that overlies it producing good crops of cereals and other things; and there are some good gardens met with on such soils, the whole of the Cabbage tribe appearing to flourish well on a soil of this description. In colour it is often a palish yellow tinge, never red nor brown, and when of good depth it forms an excellent soil for most cultural purposes. But there has been much diversity of opinion of late as to its suitability for Grape culture. On this head, however, something may be said hereafter, and I shall for the present pass on to another kind of soil, expecting to have occasion to refer to this again.

Another description of soil, and that very widely distributed, is one that overlies the sandstone and has been more or less incorporated with it. Water is usually found at an easy depth in a soil of this kind, but it is not necessarily a wet one, while it is certainly one of the most fertile we have, supporting in a flourishing state a greater number of plants that conduce to our welfare than any other previously mentioned. Large portions of the centre of England consist of soil having an origin of this kind, and it is met with elsewhere as well. In some cases the rock from which it is supposed to have originally come is all, or nearly all, gone; in others the harder parts only exist, and these waste more or less slowly as years pass on. Many of the soils having this as a base are exceedingly productive and adapted to most kinds of crops,

but there are few plots of it now to be met with in a state of nature. Past generations as well as the present have had their eyes open in selecting the most productive land, and a large proportion of this was enclosed at an early period of this country's occupation.

Decomposed sandstone supports most of the important timber trees we have, and that to a larger size than other soils, when the circumstances are equal; and in gardening it seems to hold a medium position between soils containing a large amount of calcareous matter and the peaty ones previously alluded to, in such a way that most of the plants of these extremes will thrive, and that well too, on the stratum that was once a sandstone. Witness the excellent beds of Rhododendrons and other plants of a like kind met with on soils differing in outward appearance widely from peat, while at the same time the Yew, Juniper, and other plants usually met with on chalky or limestone soils are also equally thriving; and I have a strong impression the best Grapes, as a general rule, are obtained from soils of this character, notwithstanding all that has been said about lime rubbish and the other hundred-and-one substances used as components of the Vine border. On this head, however, perhaps someone else will give us an opinion. I am certainly of opinion that most kinds of vegetables like it well—Celery, Lettuce, the Strawberry, Potatoes, and most other crops, unless it be Cabbages and Onions, which I imagine prefer the calcareous soil previously alluded to. Of course there are differences in the character of soils of the kind now spoken of. Some I have met with much more open than others, these evidently suffer more from dry summers than others do; others, again, merging fast into the stiff loam, or even clay. To this class perhaps the application of lime might be of service. But judgment is required here, and I am not sure, as stated in the early part of this article, that we do not often act improperly in some of our mixtures.

We now come to that class of soil which is far more abused than it deserves to be, "a stiff loamy soil." Somehow this soil is more found fault with than it deserves to be, owing to more labour being required in its cultivation and its unpleasantness in wet weather, but it is not an ungrateful soil, and possibly gives a better per-centage for the value of the manure put upon it than any other, as anything applied is not easily washed out of it by rains. As a soil adapted for tillage, it is one that usually withstands hot dry weather better than most others, and supports vegetation in such times with less flagging than we often see in other soils. There are numerous breadths of stiff soils scattered all over the kingdom. The London and Wealden clays are proverbial, while other districts have their tracts of stiff heavy land. It is not always in the valleys where it is to be found. On the contrary, it seems to prevail most in gently undulating countries, leaving the steep hills and level plains for other kinds of soil, although now and then it is met with there also, but that is the exception and not the rule. The general character of such land, however, does not unfit it for cultivation. On the contrary, the gentle incline and other inequalities favour draining; and the use of the plough, as well as that of vehicles, is not impeded by steep hills, while it also possesses other advantages that may be spoken of hereafter.—J. ROBINSON.

TOADS IN THE GARDEN.

MANY persons have a loathing of this really interesting, but certainly not handsome, Bufo, the result of superstition or want of education. It is time we learned that they cannot bite any more than a snake, and if they could, that bite would be equally harmless. We suppose the fiction that they carry a jewel in their head is no longer believed, Shakepeare to the contrary notwithstanding; yet the latter is more true than the former—indeed it is half true. They carry two; their eyes, at least, are as bright as any jewels that ever sparkled in a diadem. They are the most innocent of creatures that ever ate indiscriminately anything that had life that they could swallow that came within reach. They are worth more per head to the horticulturist than chickens, even allowing that chickens did not scratch; and to put our readers thoroughly in good humour with these insect-devourers, we reproduce the following story by Dr. Harris:—He supposed the odour of the squash bug (*Coreus tristis*) would protect it from the toad; and to test the matter he offered one to a grave-looking Bufo, under a Cabbage. He seized it eagerly, but spit it out instantly, reared up on his hind legs and put his front feet on top of his head for an instant as if in pain, and then disappeared across

the garden in a series of the greatest leaps a toad ever made. Perhaps the bug bit the biter. Not satisfied with this Dr. Harris hunted up another toad, which lived under the piazza, and always sunned himself in one place in the grass, and offered him a squash bug, which he took and swallowed, winking in a very satisfied manner. Twenty other fine bugs followed the first in a few moments, with no difficulty or hesitation in the taking or swallowing, though from the wriggling and contortions, it appeared their corners did not set well within. The stock of bugs then being exhausted, a colony of smooth black larvæ was found in a White Birch, each about three-quarters of an inch long, and over one hundred of these were fed to the waiting toad. Touching one of them with the end of a straw it would coil around it, and then when shaken before him he would seize and swallow it, at first eagerly, but with diminished zest as the number increased, until it became necessary to rub the worm against his lips for some time before he could decide about it. He would then take it and sit with his lips ajar for a short time, gathering strength and resolution, and then swallow by a desperate effort. There is no telling what the number or result would have been as the dinner bell rang as the 101st disappeared, and by the close of the meal he had retired to his hole, nor did he appear for four days in his sunning place. It is to be hoped that he slept well, but there might have been nightmares.—(*Western Rural*.)

GERMAN INSECTICIDE.

IN No. 619 of THE JOURNAL OF HORTICULTURE, &c., page 18, you write:—"We should be obliged by particulars of a solution that will destroy aphids and not discolour the woodwork, &c." I take the liberty to recommend to you the new insecticide, sold by Peter Smith & Co., at Hamburg, Hopfenmarkt, No. 27. The bottle containing more than 1 lb. (German), costs 2s. 6d. retail. I use it in washing and brushing all theinery—viz., the woodwork, the glass, the walls, the stems of the Vines, both for cleaning these and destroying insects, dissolving thirty grains of the insecticide in one litre of hot water. As soon as a part of the house is brushed I give a good syringing with clean water. Without injuring the most tender foliage. I use it to destroy all insects infesting plants, including grubs, dissolving twenty grains (as much as the volume of a walnut) in one litre of hot water.—D. K., a German Reader.

THE HABIT OF THE RATA (*METROSIDEROS ROBUSTA*).

R. T. KERR, F.L.S.

Read before the Auckland Institute.

THE occurrence of several climbing species of *Metrosideros* in New Zealand, coupled, perhaps, with the native application of the name "Rata" to the majority of species both scandent and erect, has led to a singular error in connection with the form now under consideration, affording a marked instance of the readiness with which erroneous statements relative to natural phenomena are accepted and repeated, although the exercise of a small amount of observation would suffice to detect the fallacy.

Few persons can have travelled amongst settlers in a forest district in the north without having their attention attracted by distorted giant Ratas, and hearing the commonly-received opinion that these immense trees were originally weak climbing plants, the stems of which increased in bulk until they killed the fostering tree which had supported them, and ultimately united to form a solid trunk, perhaps some 60 or 70 feet in length, and with the branches, perchance, attaining a total height of 100 feet. The frequent repetition of these statements has led to the error being reproduced by many superficial writers on New Zealand, although in the original "Flora Nova-Zelandiæ," published twenty years ago, the plant is correctly described as never climbing. I copy, almost at random, the following extract respecting the Rata, from Wakefield's "Handbook for New Zealand":—"Rata (*Metrosideros robusta*). There are several varieties of this tree; one grows at first as a parasite, creeping in numerous stem-like ropes up the trunks of the other forest trees, gradually enclosing them till they perish, and then uniting to form a noble tree taller than that which it has destroyed, with an enormous trunk, but hollow within." It is, however, noteworthy that this opinion is not expressed by Dr. Hochstetter and the writers of other standard works on New Zealand, who simply speak of the Rata as a large tree with showy blossoms. The general resemblance which the foliage and inflorescence of one of the

seen lent species exhibit to our plant has doubtless contributed to the perpetuity of the mistake. *M. florida*, which is also called Rata, is a climber in all stages or its existence, but may readily be distinguished by its larger leaves and flowers, its weak stems, and, above all, by the capsule being included within the calyx-tube. More than half the capsule of *M. robusta* is not included in the calyx-tube.

There can be no question that *M. robusta* is often found destroying trees by which it is supported, and these instances are adduced by the bushman as decisive proof of the climbing habit of the plant, and he attempts to confirm his view by calling the species just mentioned (*M. florida*) the young state of the destroyer, totally ignorant of the fact that he is confusing two widely-separate plants. In reality, however, our plant is exactly the reverse of a climber, the so-called trunks or stems being truly aerial roots, sent down from an epiphytic plant in search of nourishment! The seeds of *M. robusta* are conveyed by birds or blown by the wind amongst the epiphytic masses of *Astelids*, *Lycopods*, and *Ferns* so abundant in the trees of the northern forests. In this situation the plant takes root and forms a small bush, for a time obtaining sufficient nourishment from the decaying vegetation in which it is growing, until the limited supply proving insufficient for the increasing demand, its roots stretch boldly down the trunk of the supporting tree in search of that full supply which can only be obtained from the earth. Sometimes only a single root is given off, at others one main root with one or two weaker roots are to be seen, and again several roots of about equal dimensions are to be found; but in nearly all cases the different roots or stems are bound together by smaller roots, which are given off at right angles to the trunk of the supporting tree, and become united with the adjacent main roots by inoculation; not infrequently masses of fibrous roots are developed, which perish with the increase of the main root after serving their purpose of deriving temporary nourishment from the atmosphere. In course of time the various stems become inoculated to a greater or lesser extent along their course, and the supporting tree is literally strangled by their iron embrace. Notwithstanding the common belief that the stems ultimately become homogeneous, I have never met with an instance where they have united into a solid trunk. It is certainly true that straight stems of great bulk, sometimes 12 feet in diameter, are to be seen, but this is only the case when a single root-stem has been formed, or when the specimen is entirely of terrestrial growth. This may be verified by examining the position of the pith. It is, however, to be noted, that when several stems are given off the pith in each will be found much closer to the side on which the root has been in contact with the supporting tree; this, however, arises chiefly from the unequal pressure to which the root has been subjected during growth. The roots or stems may be met with of all heights up to 70 feet, and from 1 to 12 feet in diameter.

That the habit of the plant is erect, and not scandent, is demonstrated by the young plants in cultivation in our gardens; and this leads me to mention another peculiarity of this species—viz., a characteristic specimen which has been under cultivation for at least fifteen years without producing flowers may be seen in the grounds of the Hon. James Williamson, Remuera. The young cultivated plants are always rigid, erect, and bushy, exactly resembling epiphytic specimens of similar size, or specimens growing on rocks. There is no tendency to a scandent habit, and not until the young plant attains a considerable size does it afford any decided indication of a true arboreal stem. It usually produces a few much-branched stems. This has led to the belief that the plant is naturally a shrub, and only becomes a tree when placed in a position to develop aerial roots. But the opinion cannot be maintained in presence of the occurrence of large terrestrial specimens in many localities. I am fully prepared to admit their rarity when compared with the abundance of specimens of epiphytic origin; still the fact remains that in some localities they are frequent enough to attract the special attention of the bushman, who calls this form the "inland Pohutukawa," a designation he also bestows on symmetrical specimens of the true Pohutukawa sometimes found in the forest. These terrestrial specimens of the Rata are usually found in comparatively open places in the forest, while the distorted giants which started in life as epiphytes are usually most abundant, and attain their greatest development in the denser parts, a condition which of itself goes far to account for the comparative rarity of terrestrial specimens. Occasionally dwarf specimens exactly

resembling the young cultivated plants, except that they produce flowers, are found on elevated rocky places, but the cause of their stunted maturity is self-evident. It is uncertain if the aerial root of the Ratas should be considered simply adventitious, or as a special development of the original epiphytic root, although I am inclined to believe the latter. In any case the Rata stands alone amongst New Zealand trees in developing stems of large bulk, and affording valuable timber from aerial roots.

The Pohutukawa (*Metrosideros tomentosa*) sometimes produces aerial roots from the main trunk, but these are usually small and appressed. Our President has informed me of a remarkable instance on the west coast of the Great Barrier Island. The plant grows on the summit of a cliff, and has given off a root, now become an immense stem, which has travelled down the face of the cliff some 60 or 70 feet to seek its nourishment in the soil at the base. The example is so striking as to have received a special name from the Maoris. The only tree which the Rata seems powerless to injure is the Puriri (*Vitex littoralis*). A fine example, surrounded by three or four large stems, which it has forced outwards at the base, is to be seen on land belonging to Mr. W. C. Dady, by the Hotea river, Kaipara; similar instances are rare.

While on this subject I may be allowed to remark that our plant (*M. robusta*) has been largely used of late years in the place of the Pohutukawa for ship-building, it is therefore desirable that the attention of ship-builders and marine insurance companies should be drawn to the fact that for durability it is inferior to the Pohutukawa, or even to the Rawiri or Tea tree. Should its use be persisted in, considerable discredit will in a few years be brought on our shipyards. I have been informed by a well-known ship-builder that although *M. robusta* is not durable when grown on low land or in zullies, yet when grown on hill sides it is equally durable with the Pohutukawa. The Rata of the south (*M. lucida*) is not more durable, and has the additional disadvantage of splitting with the slightest blow. It is remarkable that the Pohutukawa and the Kauri, the timbers best adapted for ship-building in the colony, are practically confined to the province of Auckland, the former only having a single outlying habitat at Waitara in the province of Taranaki. *M. robusta* appears to have its centre of distribution in the Kaipara district, where it is abundant, and attains a large size. It occurs from the North Cape to Cook's Straits, and has, I believe, been found in the province of Nelson. It is, however, comparatively rare from the Waikato southwards. I am informed by Sir George Grey that only a single specimen is known on the island of Kawau, although it is abundant on the Great and Little Barriers, Waheke, and other wooded islands in the Hauraki Gulf.—(Extracted from *Transactions of New Zealand Institute*, Vol. 1.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

BRANCHED all seed weeds before they shed their seed; pull them up by hand, as cutting them up with the hoe and allowing them to remain on the ground is nearly as bad as letting them stand, for although the seed may not be ripe at the time, the sun will soon ripen it. I allude particularly to Groundsel, Shepherd's-purse, and Sow Thistle. The main crop of *Cauliflowers* for autumn use should be immediately planted on a rich piece of ground. This vegetable, when planted at this season, comes in very useful after the Peas are over. If *Cucumbers* are required through the winter, seed should now be sown, so as to have strong plants by the beginning of September. Carefully attend to those in frames, remove decayed leaves from the plants, and about twice a week in warm weather give them a liberal supply of water. Where new *herb beds* are required they may now be made; the ground should be previously dug and manured; slips of some sorts and rooted plants of others should be immediately planted in them. Thin and transplant a sufficient quantity of *Lettuces* for use; keep them watered during the continuance of dry weather. The early-planted *Onions* from the autumn sowing will probably be fit to pull up if the weather be fine; let them lay on the ground a day or two before they are hoisted, but if showery they had better be laid in an open shed. Let a sowing of *Parley* be made immediately if it was not done at the beginning of the month. If any has been left for seed, let it be gathered as it ripens, or the best of it will be lost. Earth-up and stick the advancing crops of *Peas*; the sticks from the early crops will now be out of use. Plant some *Potatoes* that have been saved from last year to produce new ones in the autumn. The rows may be closer together than the spring plantings. The Black and White Spanish *Radishes*

should now be sown for winter use; also sow the common kinds for successional crops. Continue to keep up a succession of *Spinach*; a larger space of ground may now be devoted to it, as it will not now run so soon.

FRUIT GARDEN.

Fine, mild, showery weather at this time offers a favourable opportunity for budding the stocks of stone fruit trees, and for inserting buds of esteemed kinds upon the branches of established trees, the sorts of which are not approved of. Propagation by budding, though generally confined to stone fruit, may also be resorted to with advantage in the case of scarce varieties of Apples and Pears.

FLOWER GARDEN.

There are few persons, I believe, who are fond of floricultural pursuits that do not save seeds from some favourite flower; they raise them, and watch the opening blossoms with anxious but pleasing expectations of procuring something different from what they have yet seen; but how many are disappointed in their expectations! From whence arises this? I think we can point out the reason. It is that no attempt is made to artificially impregnate distinct species or varieties having good properties, or, if it is done, it is done carelessly, and new varieties are not more likely to be obtained than by the common practice of saving seed indiscriminately from every plant that produces it, whether having bad or good properties. This I believe to be the chief reason of so much disappointment in seedlings. One person, by care and attention to impregnation, will have more good flowers from fifty plants than another who has saved seed indiscriminately will from a thousand. As an illustration of the above remarks, respecting the care with which seed should be saved, I once worked under a gardener who held a high situation, and who, thinking to produce some seedling Dahlias superior to any in cultivation, sowed seed, raised, and planted five hundred plants, most of which bloomed the first season, and those that did not were planted a second. Out of the number above named not one proved worth keeping, whilst a less fortunate neighbour as regarded means raised about forty plants, and out of the number obtained four or five good ones, some of which were in the trade for several years, and one-half were worthy of being preserved. The former sent a man round to collect seed from every flower he could. Many of our readers are probably aware that the worst flowers ripen the best seed. This was, therefore, the cause of the disappointment. In the latter case only a few flowers of the best varieties were saved, and after being carefully impregnated were covered with a piece of muslin to prevent promiscuous fertilisation, and in wet weather they were protected with a coarse canvas covering. The difference in the results needs no further comments. Continue to tie the buds of Carnations as they advance. Waxed thread wound round the top part about thrice, twisting the ends together with the finger and thumb, will be found the most safe, easy, and expeditious method. An old florist in the north used to get some Windsor Beans and cut them transversely in sections of about the eighth of an inch; when the inside was removed the rest formed a small hoop or ring. He would fit those lightly on his buds according to their size. The exposure to the air caused them to shrink, thus fitting the calyx closely, and certainly this was a very neat as well as effectual means of attaining the end proposed. Continue to plant-out rooted pipings of Pinks. Look well to the pods of seed, extract the decayed petals, and slit the calyx down to prevent the extension of wet, which will invariably cause decay and the loss of the seed. Dahlias must be regularly tied-up to their stakes, as they are now making vigorous growth. Occasional waterings with liquid manure will be of service. As we presume Tulips are all safely stored, an occasional glance to see that everything is going on right is all that is now requisite.

GREENHOUSE AND CONSERVATORY.

New Holland and other greenhouse plants will now be getting out of bloom, and some care will be necessary to avoid being short of showy plants with which to supply their places. Many plants in stoves, such as *Achimenes*, *Gloxinias*, &c., should now be in a forward state, but these must be carefully prepared for removal to the drier atmosphere of the conservatory, otherwise there will be some risk of injury. When circumstances will admit, plants that have been grown in a warm moist atmosphere should be removed to an intermediate house about a fortnight previous to their being taken to the conservatory, and gradually inured to a free circulation of air. By attention to this and placing the plants in the warmest corners of the conservatory, *Clorodendrons* and *Allamandas* will continue growing slowly and blooming for some three months at a time, whereas if this is neglected their beauty may be very short-lived. Aim at maintaining the even temperature in the conservatory, after removing plants thence that have been grown in the stove, and avoid allowing the atmosphere to become very warm on bright sunny days. Now, when many will begin to cut down their *Pelargoniums*, let me guard the inexperienced against two extremes. Formerly we used to cut our plants to mere stumps, and now some cut them by far too long for the sake of making

large specimens next year, but with care this may be effected; still the safest way for beginners is to cut the lower side shoots of this season's growth to three or four eyes, and if the plants are tall to cut-in the centre shoot to one or two eyes. Three-year-old plants make the finest specimens for ordinary use, providing the roots are healthy. Very old plants that are to be discarded had better be planted in the open ground, and they will furnish in September good cuttings which may be kept in store pots through the winter, and they will come in useful for succession next summer. Examine Heaths frequently for mildew, and apply sulphur the moment it is perceived; some of the soft-foliated varieties are very liable to be attacked by this pest. Young stock in pits will now be completing its growth, and must be carefully attended to as regards watering.

PITS AND FRAMES.

Numerous cuttings may now be put in, but particularly *Geraniums*. Pot-off such as have struck root, also seedling plants of *Lophospermum*, *Maurandya*, &c., for next season.—W. KEANE.

DOINGS OF THE LAST WEEK.

FRUIT AND KITCHEN GARDEN.

We have been looking over all the dwarf and pyramid fruit trees, stopping and thinning-out the shoots. The fruit, when it is so crowded as it is this year, on Apple, Pear, and Plum trees, should be thinned-out, otherwise it will not be of good quality; but it is not easy to find time to do everything just when it ought to be done, and when work is pressing some of the minor details are often neglected. Much may be done by method and forethought, and making an effort when it is required.

Morello Cherries trained on the north wall have been washed for the third time to destroy aphid on the points of the young shoots. A man takes the shoot in his hand and with a mat-brush applies the mixture; it is composed of tobacco water and soft soap; we read of a great many compositions to destroy this pest, but none is more effectual than this.

At this season of the year kitchen gardens have frequently a rough appearance from the crops not being cleared-off in a tidy manner: for instance, as soon as Peas are gathered the sticks and haulm should be taken away and the ground cleared of weeds. The same procedure should be followed with all other crops.

Cherry trees as pyramids on the Mahaleb stock have a charming effect when loaded with fruit, but it is no easy matter to keep the starlings from them; they attack the fruit before it is three-parts ripe, and carry off whole clusters in their bills. We have been obliged to net the trees all over, and this seems to be the only way to save the fruit.

Planted-out Coleworts after Potatoes. These are put in close together, and are cut when of a small size.

FRUIT AND FORCING HOUSES.

Vineries.—We have not much to do here except as regards airing the houses. In all we have air on at night. The Grapes in all the late houses are colouring, and at the same time red spider is putting in an appearance. We sulphured the pipes, making them as hot as we could to be safe; this, if it do not destroy the enemy entirely, checks its progress. We have not had any scalding yet; and we would just offer a word of warning to all who may have fruit of Lady Downe's Grape beginning to change colour. A close moist atmosphere will cause half the berries, or more, to scald, sadly disfiguring the bunches; while, if the ventilators are opened to their full extent, with the atmosphere only moderately moist, no harm will accrue to them. No variety is so liable to scald as this, but plenty of ventilation suits all sorts. We looked over the ripe bunches hanging in the early houses, and cut off any berries showing the least signs of decay. We are not much troubled with wasps, but flies are numerous, and are attracted by any berries which have the skins broken.

CONSERVATORY AND PLANT STOVE.

If one thing grieves us more than another in connection with this department it is growing plants until the house is too circumscribed for them, and then having to throw them away. Especially is this the case in regard to some of the *fine-foliated plants*, which grow rapidly, and very soon fill a large space. We had to dispose of some of our largest plants, and this gave us an opportunity to repot younger specimens of Ferns and other stove plants. We are rather particular in potting Ferns; it is owing to the careful manner in which they are potted and the compost mixed, that success is attained. An unhealthy specimen of a Fern, or, indeed, of any ornamental-foliated plant, is not worth house room; it is owing to the freshness and health of the foliage that they are esteemed for decorative purposes. The potting must be performed in a systematic manner. Clean pots of different sizes should be ready to hand, the crocks ought to be clean and placed carefully at the bottoms of the pots, over them drainage should be placed, then some very fibrous loam or peat. The compost for most sorts of Ferns should be turfy loam and peat in about equal

proportions, and in potting press the soil rather firmly around the ball of the roots.

We have been repotting softwooded plants of different sorts to supply us with cut flowers for decorative purposes in the autumn, and putting in some cuttings of the best sorts of Zonal Pelargoniums, which are very valuable for the same purpose. Amongst the plants potted were *Phloxes* (*Phlox decussata*); the cuttings were inserted singly in 3-inch pots about six weeks ago, and have made good growth; being now in 5-inch pots, they will flower in the autumn when the others are over, and very useful they are for arranging amongst greenhouse plants. They take up no room, and the long stems are hidden amongst other plants. The flowers have also a very agreeable perfume. It may not be out of place to name half a dozen of those best-adapted for pot-culture: *Anranitiaca superba*, *Madame Damage*, *A. P. Barron*, *Mons. Linden*, *Mons. Murin Saison*, *Queen Victoria*, and *Venus*. After they have done flowering they are removed to a cold frame for the winter, and make excellent plants for planting-out in the spring.

We also potted-on *Tea Roses*: these are very valuable for autumn flowering. The plants are making vigorous growth, and only require to be kept free from green fly, red spider, and mildew to reward us with a splendid bloom. We also accommodate such plants as *Bouvardias* of sorts, *Eranthemum pulchellum*, *Thyrsacanthus rutilans*, &c., on shelves in the Cucumber house; they will each in order reward us with plenty of flowers during the dreary winter months. We have been repotting those requiring that attention, and tying and placing sticks to those plants in want of support.

FLOWER GARDEN.

The weather this year has been favourable to continuous bloom in the flower beds, and we do not think they have ever looked better. No artificial waterings have been given to the plants, except in the case of one or two of the beds which had become dry from not receiving the whole of the rain that fell. Both in the flower and kitchen garden we advocate deep trenching, and placing some of the manure at the bottom of the trenches as well as near the surface. Roses are now far past their best, and all flowers are removed as soon as possible after they are showing signs of fading. Attention is also given to removing all suckers from the base of standards, as well as from dwarfs on the *Manetti* stock. Through ignorance, we have seen this stock entirely smother the Rose that had been grafted upon it, and the shoots of the *Manetti* had been annually pruned, the owner, however, looking in vain for Roses. Other work consisted of mowing the lawn, trimming the edgings, and making all neat and clean in the garden.—J. DOUGLAS.

TO CORRESPONDENTS.

* * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

THE JOURNAL IN NEW ZEALAND (G. J.).—By far the best way for you to procure the Journal safely and expeditiously is to send your subscription for a year direct to the office here in London, and the paper will be posted to you weekly. You will see the terms of subscription published at the top of the first advertisement column of each number. We know the difficulty you labour under, as we have frequent complaints, and this is the best remedy.

VARIEGATED SWEET WILLIAM (J. F. G. G.).—Your variegated-leaved Sweet William appears to be a very pretty thing.

PLANTING A WALL (De Bush Subscriber).—The best time to plant fruit trees is as soon as the leaves have fallen. Do not plant them on a mound, and do not make the soil too rich. Your garden would be better of a hedgesing.

PRESERVING MELONS.—A correspondent is anxious to know of a good receipt for preserving Melons whole; any information on the subject will be esteemed.

ROMAN HYACINTH (W. D.).—The Roman Hyacinth grows wild in France in the southern departments, but not at Lyons. You will find it at Cannes, Narbonne, Toulouse, and in the basin of the Garonne. It also grows about Rome, and on the coast of Barbary.

PLANTING TREES (D. J.).—The concluding paper of the series on ornamental planting will be devoted to general details, among which the subject of your inquiry will be fully explained.

FRUITING FORBED STRAWBERRIES IN THE SECOND YEAR (T. J.).—The plants got turned out from pots last year, and which have produced a good crop this season, will bear again well next year if the runners be duly removed and the plants well watered in autumn, but the fruit is rather smaller than in the first season after planting out. The plants put in last year, and which have borne scarcely any fruit in the present season, will fruit well another year, remaining where they are, and the runners cleared off. It would not do to remove the plants to another part of the garden.

GRAPES NOT SWELLING (G. J.).—The berries do not swell because they are not set. You may effect this artificially, by going over the bunches whilst in bloom with a dust brush, such as painters use, or by drawing the hand lightly

over them. Some Vines, however, are at best bad setters, requiring more heat than other kinds to swell well. There are no insects on the leaves sent us, but evidence of there having been thrips, the remedy for which is to fill the house on a calm evening with tobacco smoke, repeating the dose the next night but one. Have the foliage of the plants dry, but the floor of the house wet.

MELONS FAILING (*Anxious*).—The failure probably arises from want of bottom heat, too much moisture when setting, and overcrowding the plants. When the flowers are on the point of setting, the bottom heat should be 75°, and the air of the house should be dry; a little air may be admitted at night to prevent the deposition of moisture on the blossoms, and no water should be given over the leaves or flowers; if any be needed at the root it should be applied without making the surface of the bed moist. After the fruit is set and begins to swell, water will be needed until ripening, and its use should then be discontinued. One plant on each mound is quite sufficient, and its principal shoots should be 1 foot apart. We apprehend you have a mound to each light of about 3 feet 6 inches wide. In other respects we do not see that your treatment is wrong.

CUCUMBERS IN POTS (H. J.).—They may be grown successfully in pots; we have grown them well in 11-inch and 13-inch pots, but we like them best in 15-inch pots. We suppose the pots will be plunged in some material that will be heated by the two 4-inch pipes; or are the pots simply placed between them? If they have the sides of the pots against the pipes the roots will probably suffer from the heat. The pots should stand clear of the pipes, or they may be placed on them. It would have been preferable to have had the wooden-lattice frame 4 inches above rather than below the plants. Your frame or pit to be worked from the outside will not be of much use for winter work, as it will not be advisable to open the lights in continued frosty weather to duly attend to the plants. They will, no doubt, answer well for summer work.

MELON TREATMENT (J. W. L.).—The cause of the Melons turning yellow and not swelling is because they are not set, or impregnated, and that may arise from too close and moist an atmosphere, or it may be due to a deficiency of bottom heat. Give rather more air when about setting, leaving a little on at night if at all moist, and have the surface of the bed dry, but the soil daily moist. Three or four fruit are not too many on a plant if they are vigorous. It is proper to stop one joint beyond the fruit, and about the time the flowers expand is the time to stop them. Liquid manure may be given at every alternate watering after the fruit commences to swell, but it should be weak.

NAME OF FERN (*Idem*).—It is *Adiantum assimile*, a very useful kind for bouquets. *Adiantum emarginatum* is pronounced *cu-ne-a-tum*, not *cu-nat-um*.

ESCALLONIA MACRANTHA (*Myr. Kenilworth*).—In your part of the country this should have the protection of a wall.

PLANTING VINES—HEATING (*An Old Reader*).—Intending the houses for plants as well as for Vines, we should not plant the Vines closer than 3 feet 10 inches, or one to each light, and by all means have them planted inside. For the earliest and latest house we should have the borders the entire width of the house, except, perhaps, the pathway at the back. In the other houses the 4-feet inside borders will do. It would not answer well to have 1-inch flow and return to the other houses through the early house, nor would we have any in the other houses, save those which are required for heating, but, instead, a 4-inch flow and return outside the houses, and take branches from it as each house was reached. The supply pipe might pass through sheds which might be used for growing Mushrooms and forcing Rhubarb, Sea-kale, &c. The flow and return supply pipes might, if you object to this, be taken in a flue under the back pathway of the houses, and might either be covered-in or a lattice pathway made over them. The heat they would give off would be beneficial rather than otherwise, especially as you intend to have plants. It is desirable to have the front lights made moveable and double, so as to form a narrow space in which the Vines can be placed when at rest. The house by this arrangement will be liberated for the growth of plants requiring a temperature hurtful to the Vines. This arrangement you will find fully treated of in "Sudlers on the Vine," a work published at our office. Notwithstanding the subsoil being dry and sandy, we should concrete the borders, secure perfect drainage, and confine the roots to the border. For the early house we recommend three Black Hamburgh, three Buckland Sweetwater, and two White Frontignan; this house to be started in November. Second house, started in January, Frankenthal, Black Prince, Muscat Troyen, two Mill Hill Hamburgh, Black Muscat of Alexandria (Muscat Hamburgh), and two Muscat of Alexandria. Third house, started in February or early in March, two Frankenthal, Trentham Black, two General de la Marmer, Black Prince, Muscat Troyen, and Golden Hamburgh. It is presumed you will have Muscats remaining from the second house to come in along with the other kinds in the third house. Late house, Muscat of Alexandria, two Mrs. Pince, Alicante, two Lady Downe's, West's St. Peter's, and Trebbiano.

BROWN TURKEY FIG NOT RIPENING (G. S.).—This variety does well with us in pots, and why it should not succeed with you while the others ripen we cannot say. When Figs are grown in pots under the shade of Vines we have found them drop off before they are ripe. In your case the trees might have received some check from under or over-watering at the roots.

PLUM NOT BEARING (*Anxious*).—We can only account for your tree not bearing so well as your neighbour's from the fact that his tree, having the protection of a wall, receives more warmth while in flower, which causes the blossoms to set more freely. When fruit drops off when of the size of peas, it is because the blossoms did not set. Your district may be too cold for this sort as a standard or pyramid. In the south of England it bears abundantly as such.

POTATOES WITH MITCH HAULM (*South Hackney*).—The Potatoes you have planted are robust-growing sorts, Sutton's Red-skin Flourball especially so. In all probability your garden is shaded or confined in some way. You ought to plant them wider apart in the rows than usual, and the rows should not be less than 2 feet apart. Cutting away some of the haulm will not increase the size of the tubers. It is early yet; if you wait a few weeks perhaps the tubers will swell.

STRAWBERRY PLANTS (G. W. O.).—Any of the nurserymen in your neighbourhood will supply you with strawberry plants. There are surely nurserymen at Blackheath.

WEEDS ON LAWN (*An Old Subscriber*).—Such weeds as your lawn is infested with are very difficult of removal, except by hand-weeding and destroying the flowers so as to prevent seeding. Although weeding is a tedious process, it will no doubt have the effect of gradually extirpating the pest.

MARCHEL NIEL ROSE (*A Beginner*).—No doubt Marchel Niel will do well in the situation you mention. A good strong loam will suit it.

BANANA FRUIT DAMPING.—**POTTING POINSETTIAS** (*Subscriber*).—The cause of the Banana fruit damping is probably too close and moist an atmosphere. When ripening the atmosphere should be rather dry, and only moderate supplies of water must be allowed at the roots. Probably the fruit is wetted by syringing or drip from the roof, or the damping may result from an injury in undue handling. Poinsettias from cuttings of this year may be bloomed well in 7-inch pots; it is now high time they had their blooming-pots, but it is not too late. The cuttings now 1½ foot high are too tall; take off the tops with three or four joints, and insert them singly in small pots in sandy soil. Place them in a horse or frame in gentle bottom heat, keep them close and shaded, and they will soon root. When the pots are full of roots sink the plants into 6-inch pots, and keep them near the glass. They will form dwarf plants with fine heads.

FUCHSIAS IN WINDOW NOT FLOWERING (*X. Y.*).—Probably the plants need repotting. We presume you cut them in February, kept them rather dry until they had made shoots an inch or two long, then repotted them, removing most of the old soil, and when these pots were full of roots shifted the plants, watering as required to keep the soil moist. Either the soil is sordid or the plants have too dry an atmosphere or soil. Guano, 1 oz. to a gallon of water, is probably the best for window plants. It may be given at this strength to all plants in active growth, but not when they are not growing. The only thing we know of that you can do with your hard water for drinking purposes is to have it filtered.

PEAS LYING (*W. Jones*).—We think the Peas you enclosed to us have had the outer covering of the stem destroyed by snails or slugs. Dust the ground over the rows with quicklime before the plants appear, and every week until they are sicken. There is evidence of mildew, which will yield to the lime. A dressing of manure and salt, two parts of guano to one of salt, sprinkled along the sides of the rows before earthing-up, would be very beneficial, but keep it off the Pea lambs. The ground should only be made yellow.

STRAWBERRIES FRUITING (*Id. m.*).—The not-dragging between the rows and so not interfering with the roots is sufficient to account for the plants producing a greater crop than those of which the roots were disturbed by digging. Strawberries are, however, as a rule, very fine and abundant this year.

ROSE BUDDING (*Id. m.*).—We consider the first fortnight of July, or as soon as we have a moist weather after the flowers are shed from the plants, the best time for budding, and it may be practised up to the end of the month.

IVY SCEDDING (*E. L.*).—Scedding Ivy plants are just as good for covering walls as those from cuttings. The best time to remove them is in October; take them up carefully, and give a good watering after planting. From September to April they may be moved quite safely.

FLOWER BEDS.—**BEDDING GERANIUMS** (*Id. m.*).—When the plants in the flower beds are fully grown no portion of the soil should be visible, and where they meet the grass, the edging, neatly trimmed off, should not expose any portion of soil, or a very small margin. It is hard to say which are the best four bedding Geraniums, crimson, scarlet, pink, and rose, but the following are superior sorts:—Chimion, Bayard and Waltham Scedding; scarlet, Jean Sisley and Vesuvius; pink, Master Christine and Mrs. Upton; rose, Beauty of Dulwich and R. Evans. We have named two of each.

DESTROYING MEALY BUG (*W. J.*).—The best remedy would be to cut the plant away, and have the house thoroughly painted. It is of little use striving to get rid of it by the application of insect-destroying compounds syringed on, as the plant being so dense, the solution would fail to reach every part. Thin it out, and syringe forcibly, the greater force the better, with clear soot water, made of one peck of soot to thirty gallons of water, stirred well up, and strained before use. Do this twice a day, and in time you will overcome the mealy bug, or keep it under. If you could take the plant down, immerse it in Clarke's compound, at a temperature of 12° F., and then sponge it thoroughly, and again immerse, it is likely you would annihilate the pest. The compound should be 3 ozs. to the gallon of water. It may be advantageously syringed on; the only difficulty is to thoroughly wet the plant, and of course reach the bug in every part.

VINE LEAVES SCALDED (*Joseph Dutton*).—This is caused by lenses formed in the glass, or by insufficient ventilation.

CALECOLARIA PROPAGATION (*S. A. E.*).—If your *Calecolaria* is of the shrubby class you can not only preserve your old plant to bloom again next year, but you can also take cuttings from it to preserve over the winter; but if it is what is called an herbaceous variety, you may have some trouble with it. Your Vine leaves are searched through thickened places in the glass forming lenses.

PEAR CRACKING (*A. Clorbo*).—We suspect your soil is dry and sandy. Give abundance of water in dry weather, and mulch the soil round the trees.

CLASSIFYING ROSES (*A. Conant Subscriber*).—The classification of the varieties of Roses is very arbitrary, and it is not easy to define what is a Bourbon, a Noisette. Both of these were raised by the hybridizing of species, and now the varieties have become so crossed it is impossible to give a correct definition of either. You can get the work you require by applying to Mr. B. S. Williams, of Upper Holloway. There is a supplement to the "Glossary to Gardeners' Dictionary," published by Bell & Dalry.

WINDS ON WALKS (*H. J.*).—The ashes will not injure the *Polypodium*. *Aclimacium* *Sampsonii* is a greenhouse climber; and we have no experience or knowledge as to its being able to withstand the winter.

FROGS ON HOLLYHOCKS (*E. C. E.*).—The fungus is *Phenicia maculosa*, *Mon.*, which abounds everywhere this year in England, though it has only been observed on Hollyhocks in Australia only. It was first noted in Aitha in Chili. Mr. Broome has found it on the common Mallow. How it was introduced into this country is unknown. There is no chance of getting rid of it except by burning at once the infected plants.

INSECTS (*Subscriber, Lincoln*).—The small insects which have attacked your Strawberries are a species of millipede, or "forty-feet," named *Julus pulchellus*. The ground must have been foul, as the insects are reared in decayed vegetable matter. We know no other remedy in their present condition than carefully cleaning the ground beneath the plants and picking off the decayed leaves.—I. O. W.

NAMES OF PLANTS (*J. M. C.*).—*Eriophorum angustifolium*. (*A. C.*—*Hemerocallis disticha*. (*C. Clifford*).—*Carex luteo-lucida* (*Euchaeter's Nidula*—*Salic.*). (*H. D.*)—The fruit of a Fern is on the back of the frond, and there is none on either of your specimens. We cannot name plants from leaves only, and your specimen No. 6 is only leaves. (*A. M. X.*)—1, *Alantum tenerum*; 2, *Spiraea erantifolia*; 3, *Passiflora racemosa*; 4, *Pasiflora caribaea*; 5, *Selaginella coccinea*; 6, *Selaginella Mortensii*. (*Dorham*).—*Astrantia maxima*.

POULTRY, BEE, AND PIGEON CHRONICLE.

COTTAGE POULTRY-KEEPING.

IN answer to your correspondent "RECTOR," will you allow me space for a few words in vindication of the policy adopted by farmers in general in forbidding their labourers from keeping poultry? "RECTOR" states that he "has often and often spoken to his poorer friends upon the beneficial results in every way of keeping poultry." I can assure him he is perfectly wrong. As a practical poultry-keeper of more than twenty-five years' experience, I state boldly that poultry-keeping cannot pay in England if you keep a proper debtor and creditor account of your expenses and returns, and the only possible manner in which a cottager would find it answer to keep poultry would be by turning them out to pick up their own living as best they could, or, in other words, to feed upon the neighbouring farmers' crops. It is utterly impossible "to restrict them to the roadsides," as badly-fed poultry will roam away great distances in search of food; and anyone who has had practical experience knows that poultry, besides what they actually consume in the corn and hay fields (and that is very considerable), do an immense deal of damage by scratching up the seed and by tramping down the corn and moving grass before the harvest begins. Corneraks are considered bad enough for this, but poultry are fifty times worse. In my own case my poultry render useless, and quite unfit and impossible to mow from this very tramping, about three acres of a field every year reserved for hay. Again, farmers know full well that during winter, if at no other time, there is a great temptation to the labourer to fill his pockets with corn from his master's granary to keep his poultry from starving to death—a temptation that would not exist had he no poultry to feed.

In the southern districts of Sussex the farmers may, as you say in your editorial note, allow the cottagers the free range of the fields after the harvest is ingathered, but if they do it is an extraordinary exception, and those who do not do so should not be called "selfish and flinty." The gleanings of the cornfields is a valuable product of the farm, and it is customary for the farmer to turn in his own poultry, Turkeys, Geese, and pigs, which thrive and fatten well upon it. In the north of England vast numbers of young Geese, imported annually from Ireland, are bought by the farmers for the express purpose of being turned into the cornfields as soon as the harvest is gathered, and by which means they are fattened and got ready for the Michaelmas market at a scarcely perceptible cost. No one can have a greater desire than I have to improve the status of the agricultural labourer, but I am fully convinced that this cannot be done by trying to induce him to believe that he could keep poultry at a profit, if his master and employer would only allow him so to do. Let him try. Let him feed his poultry well enough to keep them near home; let him agree to pay reasonable compensation for all damage done to his neighbours' crops, hedges, &c., and I think he would very quickly arrive at the conclusion that cottage poultry-keeping was a delusion, without any beneficial results whatever.—E. C. C.

P.S.—I am firmly convinced that breeding and rearing the common tame Rabbits can be made most profitable by cottagers. Being kept in confinement they cannot trespass; they can be fed on sow thistles, grass, &c., gathered from the roadside; they increase rapidly, and the more wild Rabbits are exterminated as vermin, the higher will rise the price of tame ones. In your last Journal they are quoted at 1s. 5d. to 1s. 6d. each.

LITERARY PIRACIES.

THE article we published last week on the "Management of Setting Hens," and quoted from the *Colonial Farmer*, is, we find, an extract from Mr. Lewis Wright's "Illustrated Poultry Book." The practice, which seems very common among our transatlantic brethren of copying from British books and publications without acknowledgment is, to say the least of it, highly reprehensible. We are sorry to say that our own periodical press is not free from the same imputation. It may be considered by those who practise it a smart thing to do, but all honest and honourable men regard it as something very different.

CLECKHEATON POULTRY SHOW.

THE fifth Show was held on the 19th inst. in grounds admirably adapted for the purpose; and although the pens used were of a primitive description, having strained canvas for the backs, and a roll of wire tacked on from end to end for fronts, the birds showed to much advantage. In the Pigeons, however, the pens for the Pouters were decidedly too small, as the birds could neither stand erect nor comfortably turn in them. The supply of food and water was ample, and the general attention exemplary. Although for many days previously the

the National Peristeric Society, Birmingham, or the Manchester Columbarian Society, who might address a note to his fellow presidents, and so start the affair. Arrangements might be made for the show to be held in the Crystal Palace, or, if not too late, in conjunction with the forthcoming Crystal Palace Poultry Show. Success would be certain. Union would be strength, and at least fifteen or eighteen hundred peas of birds would be brought together.

If you will permit me I will say a few words how I think the affair should be worked. Make the show self-supporting, none but members of Society to exhibit. The show to be divided into two sections—old birds, and birds bred in 1873, all single birds; classes to be made for every variety of colour of Pigeons; an entry fee, say, of 3s. to be charged for each entry, half of which should be deducted for expenses, the rest divided into first and second prizes according to the number of entries in each class—that is, if there be twenty in one and ten in the other, 30s. to go to the former, 15s. to the latter; at the same time to have challenge cups in each class, acceptance £1 1s. each, exhibitor to challenge for as many as he may choose. The value of the cup would vary according to the number of acceptors in each class. All birds shown by an exhibitor in any class when he accepts a challenge to compete for the money prizes, only acceptors for the cup.

The most difficult point would be the appointment of judges to please all parties. The course I would suggest is that every Society nominate a gentleman, who should act, whether he be an exhibitor or not; if an exhibitor, let him officiate in other classes.—A.

Simple Mode of Keeping Butter.—In warm weather where ice is not handy invert a common flower pot over the butter, with some water in the dish in which it is laid. The orifice at the bottom may be corked or not. The porousness of the earthenware will keep the butter cool. A wet cloth laid over the inverted pot will soon cool-off the butter by the evaporation of the moisture.

OUR LETTER BOX.

Books (—).—Vol. xxvi. (first edition), of the "Naturalist's Library," was written by Dr. Dunbar. Apply to James Thin, Bookseller, 15, Infirmary Street, Edinburgh, and he will probably be able to furnish it, and also the works of Golding and Bevan. Dr. McKenzie's, "The Management of Bees," was published by Blackwood & Sons, Edinburgh, and cost 4s.

COMMENCING POULTRY-KEEPING (Nemo).—You can make your poultry pay without going to much expense. You do not require all the wire appliances that belong to the fancy poultry-yard. Build a wooden house, such as you will find described in Bailey's poultry book. Buy some wire netting 39 inches high, and stretch it round the run you can give them by means of stout stakes at intervals. Keep either Cochins or Brahmas. They will lay lots of eggs, and you can spare a corner of the orchard or kitchen garden for the chickens.

DARK BRAHMAS' FEATHERS (A. H. J.).—The Dark Brahma pullets would not be disqualified. It would be better if they were pencilled up to the beak, but such is very seldom the case—hardly ever. The light breast is very preferable to brown backs or wings. A purely white breast would be a disqualification, but one lightly pencilled on a light ground is not. Such a bird in competition with others that were well pencilled all over would, however, be beaten. The Game chickens hatched at the end of April might well be shown, but the cock must be dubbed, and he is full young. You may, if you have several, dub one for the especial purpose.

PARASITES ON FOWLS (O. P. Z. H.).—You will find nothing so effectual as carbolic acid. Drive a mixture of it well into every hole and crevice with a syringe. Scrub the perches and laying-boxes with hot water and carbolic acid soap; lay it on all the woodwork with a brush. Dig the flooring out about a foot deep, and fill-in with gravel, road-grit, and lime. Use your carbolic acid largely in our fowl-houses and dog-kennels. Ordinary bugs flee from the smell of camphor; you should be disposed to try it on these.

RABBITS FOR PROFIT (H. S.).—It depends entirely on what you propose to do. If you are in a neighbourhood where there is a sale for Rabbits for the table, then you should keep that which is called, and is, the common tame Rabbit. A well-fed healthy doe will fatten four "from the test," and they in London make 1s. 6d. each at seven or eight weeks old. If for a town where wild Rabbits are not to be had, and where they are bought, as the Oxford Rabbits are in London, by weight, you must have the Belgian Hare Rabbit. If you wish to breed to sell fatter Rabbits alive, you will do better with the Silver-Grey than any other. There is always a sale for them at remunerative prices. If the crusade against them is successful, and the wild ones disappear, Rabbit-breeding will become a large trade. We are in a transition state as regards food and cooking. It is enough to have more money to spend, but it is essential to make the money do more towards feeding a family, and that can only be done by laying out the money to the best advantage, but also by cooking skilfully. We often propose to devote a column to the subject.

BEE MANAGEMENT (S. A. B.).—We should advise you not to plunder your swarms of June 2nd, either in whole or in part. Let them be for another year, unless you absolutely want honey; in this case we would plunder one hive entirely, driving the bees out and joining them to the other hive. Much honey is always wasted, and the stock itself weakened, by a partial plunder. Write to the Messrs. Neighbour, of Holborn, London, or to some other purveyors, and see whether you can get into the London market through them, or else establish a market in Dublin by co-operation with other bee-keepers. If you can but open a connection with some respectable grocery firm, and supply them with really good honey in or out of the comb, you will surely find a ready sale.

BEE COMMOIONS (John Douglas).—We cannot explain without an inspection of the hive what caused your bees to be so troubled. Perhaps some young queen returning home from her matrimonial flight mistook the hive for her own, and was ejected, or perhaps it was an old queen of their own of whom they

were tired. In any case we do not think you have occasion for alarm; at this time of year bees can always replace a lost queen. Queens are liable to strange treatment at the hands of their own subjects, but the causes are not known.

BEE FLOWERS (A. P. Waters).—It is of little use to grow flowers of any kind specially for bees, unless you grow them by the acre. They are very fond of Monardella, Borage, Melilotus leucantha, blue Lobelia, Crocuses, Buddleia globosa, Thyme, Spiraea of all kinds, &c.

BEES IN ADVERSE WEATHER (P. R.).—1st. During wet or dull weather in summer, when bees are unable to leave the hive, work of some sort can generally be carried on. Combs can be built with wax secreted by the bees from honey previously gathered, so that we can often observe considerable progress to be made. Then, again, the brood, if any, requires constant feeding and attention, and when sufficiently matured their cells to be capped over. Should the unfavourable weather continue long, comb-building operations must cease. 2nd. In bad weather swarms should be assisted by feeding the bees with boiled sugar, in the proportion of 6 lbs. of sugar to 4 lbs. of water, by weight, boiled for five minutes. Feed alternate nights, giving 1 lb. at a time. 3rd. If a first swarm, which will have the old queen, breeding will commence as soon as there may be a few inches of comb available. If a second swarm or cast, with favourable weather the young queen may lay eggs within a week after it was hived, or her laying may be considerably delayed if bad weather has prevented her going forth to meet the drones.

REMARKS.

- 16th.—A very fine day throughout.
 - 17th.—Very fine all day, a cool breeze making it still more agreeable.
 - 18th.—Wet early, but fine soon after 10 A.M., and though there were occasional showers, a very pleasant day and starlit night.
 - 19th.—Lovely day, very bright and yet cool.
 - 20th.—Rather dull at 8 A.M., but fine by 10 A.M., and afterwards; a complete summer day.
 - 21st.—Rather hazy early, but a warm fine day.
 - 22nd.—Very fine all day, and the hottest day this summer, notwithstanding that the wind was northerly and the sky occasionally cloudy. Much lightning in W., after midnight.
- Warm week, especially the last two days. The temperature reached 80° at 9.15 A.M. on 22nd, and 90° between 2 and 3 P.M. It is somewhat remarkable that the 9 A.M. temperature on July 22nd, 1872 was 79.5, and on the corresponding day and at the same hour in 1873 it was 79.4.—G. J. SYMONS.

COVENT GARDEN MARKET—JULY 23.

A VERY steady trade and good supply. The markets are well attended, and large consignments are forwarded to the midland and northern ones. All the bush fruit and standard cherries are of excellent quality this season. Strawberries alone, with the exception of one or two varieties, have not been up to the mark in point of quality. Importations continue large, including West Indian Pine Apples.

From observations taken near London during forty-three years, the average day temperature of the week is 74.9; and its night temperature 50.6. The greatest heat was 92.0, on the 2nd, 1856; and the lowest cold 31.1, on the 2nd, 1854. The greatest fall of rain was 1.23 inch.

BRUSSELS SPROUTS AND WHITE BROCCOLI CULTURE.

THE first of these is, perhaps, one of the most useful of vegetables for affording a supply during the winter months, especially to the owners of small gardens. To such I confidently recommend it, and for their information I will offer a few remarks on its culture.

In the first place, a good stock ought to be obtained, and after a lengthened experience I can affirm that I know none that entered in the seedsman's catalogues as "Imported Brussels Sprouts." These usually throw-up a stem averaging 4 feet high, thickly studded with compact miniature Cabbages, ranging from half an inch to an inch in diameter. For small gardens one sowing will be enough, and this may take place about the middle of March. Here I may offer a word of warning to our amateur friends; they generally buy the seeds at a cheap rate, and sow them under a Gooseberry bush, or in some similar position. The best seed should be procured, and it should be sown thinly in an open position on soil that is not too rich.

As soon as the young plants are sufficiently advanced they may be planted out in the ground which has been previously prepared for them. This ought to be done in winter, and, to obtain the best results, it should be trenched at least 18 inches deep, and be well manured; ordinary farmyard manure is the best. The plants will be ready for planting-out as soon as they have made three or four leaves besides the seed leaves. In taking the plants out of the beds a small fork should be used to loosen them first; then pull them out gently, laying them in a box or flat-bottomed basket. When the ground is in good order, and the plants are put out early, they should be 2 feet apart each way.

In planting-out, drills should be drawn 2 feet apart, and the plants be put in with a dibber in a careful manner, making the earth firm round the small fibres. The drills will be found useful; if it be necessary to give water to the plants they will allow of its soaking to the roots. I have seen a man planting-out such crops as this; he ranges a line on the level ground, and in planting he draws the earth up to the stem with his dibber and forms a small mound over the roots; of course it is sheer waste of time to attempt to water the plants, unless the ground can be flooded, as they do on the sewage farms. In all planting during the summer months a shallow depression ought to be left round the stem of the plant to retain the water.

In many small gardens it is necessary to make the most of the ground. When this is the case, instead of planting out the Sprouts at once, let the plants be pricked-out about 3 inches apart in a bed, and when the earliest crop of Potatoes or Peas is gathered, the plants may be put out on the vacant space; or they may be planted between the rows of Potatoes, in which case

the plants will be established before the Potatoes are forked-out.

A firm soil seems to suit the growth of this vegetable best, and it is cultivated most successfully on a clayey loam.

Then as to the time when it may be used and the manner of gathering the sprouts. They are most useful between the end of October and March, and should be gathered when the little round heads are firm and compact. Some persons cut off the head as soon as the sprouts are ready for gathering. I do not see the utility of this. No doubt the sprouts near the top will more rapidly become larger if this be practised; but, on the other hand, as the stems lengthen more sprouts are formed, which come in later in the season.

WHITE BROCCOLI is another very useful vegetable; but, even more so than the preceding, it delights in heavy soils. Now is the time for planting-out the latest sorts. The ground for this should be hard, and if it is necessary to let the plants into the ground with an iron bar they will succeed all the better. Those who plant their Strawberry beds annually cannot do better than plant their Broccoli on the old beds; all that is necessary is to clear-off the weeds and Strawberry plants, and as the ground will be hard, the plants may be let in with a crowbar. The same after-treatment is necessary both for Brussels Sprouts and Broccoli, hoeing the ground over as often as weeds appear.—J. DOUGLAS.

THE WEST OF ENGLAND ROSE SHOW, HEREFORD.

As there has appeared no account whatever of the above Show, and as I heard the Hon. Secretary and others regret the absence of your usual reporter, it occurred to me that a few notes might be acceptable to you, made as they were in my double capacity of judge and exhibitor. Indeed, I should feel very sorry were so grand a Show to come and go without any notice in your paper, which in my opinion far exceeds all other horticultural papers in the accounts of all (but particular Rose) exhibitions. The journey to Hereford from all places, but particularly from the west, is a difficult one, for have we not to pass through Bristol? and is not the present station the worst in existence, and are not the platforms so narrow and crowded, that it is a matter of the greatest difficulty to preserve your blooms from annihilation by reason of the porters' desire to turn them upside down? So when I relate that we western growers were landed at Bristol just in time to see the last train for Hereford steaming out of the station while we were struggling with our boxes, no one who knows the fine the Great Western keeps will think it an unusual event.

However, we got as far as Gloucester that night, and knowing that there was a train from that place which would just land us in time at Hereford to put in an appearance at the Shire Hall before the doors were closed, we secured beds at the "Duke of Wellington," and were as comfortable as civility and good accom-

modation could make us. We do not seem, I am bound to say with all regret, to have made others comfortable, though, as the following anecdote will show. That great rosarian who swept the board this year at the Crystal Palace, taking three first prizes in the amateur classes, and one in the open—that monarch of the amateurs and your humble servant were accommodated in two rooms leading one from the other, and were called at the early hour of six. We talked and laughed without dreading of doing anybody the slightest injury. But our ignorance on this point was soon enlightened, for just before we left Gloucester a friend who had met with the same ill-luck at Bristol, told us that there were the most serious complaints against us, and he did not know whether we should be allowed to leave. It appears an old gentleman had come down to breakfast in a great state of distress, not to say anger, and accosted the waiter with the question, "Did I not ask you to give me a quiet room?" "Yessir, and so we did, the best in the house." "No, you did not; you put me in one next to where two men were sleeping, who did nothing but talk and laugh all night. I believe they were commercials, for they were talking of flowers, and vans, and telegraphing, and of taking a nursery." Our friend here interrupted, saying we, at least, were gentlemen, one was a clergyman, and the other one of the greatest cultivators of the queen of flowers. "But, no," said the aggrieved man, "they were *commercials*, and one of them had such a terrible loud voice." With this embarrassing piece of intelligence we departed, and after much labour staged our blooms in the Shire Hall. And then how we were repaid, not, I do not mean with prizes, though we had our share of them, but with the Roses exhibited by others.

When the Hall was cleared, and we commenced to judge the nurserymen's classes, I do not think we ever had a greater treat; I know I never had. Mr. Cranston showed magnificently; his seventy-two singles and his forty-eight troubles surpassed anything I have ever seen; while, to cap all, he had positively staged twenty-four blooms of Horace Vernet, each Rose of which was as large and as perfect in form as the finest Charles Lefebvre I have ever seen. Now, down here we cannot grow this Rose. Mr. Keynes has given up cultivating it; Mr. Baker, I believe, can rarely show it; I can only get it as large as a half-crown piece; but here Mr. Cranston gave us twenty-four specimens, each bloom faultless, standing high up from the moss, with the most luxuriant foliage it is possible to imagine. "Hurrah for the Manetti stock!" I cried, and Mr. Baker and Mr. Charles Turner, the two other Judges, echoed the cry, "Hurrah for the Manetti stock!"; for our friend was showing almost entirely from that stock. No more can it be said that you cannot give us show blooms, or blooms equal to the maidens on the Briar. I would that the Rev. S. Reynolds Hole could have seen those stands from King's Acre which made the Show something to be never forgotten, and he would, I am sure, in his next edition strike out from his "Book about Roses" the one blot, to my mind, the one misleading statement, that "the maiden blooms on the Briar are much superior to those on the Manetti; and that anyone who is compelled to grow Roses only on the latter stock should give up all idea of exhibiting." Mr. Turner and Mr. Baker both declared they had never seen anything like those stands in their life, and that they should never forget them. Roses, too, which most of us have long condemned were shown magnificently. Such sorts as Jean Pernet, Prince Henri des Pays Bas, Julie Touvais, Alfred de Bougement, and others were really superb. The only drawback was that there was so little competition in these classes; Keynes, Paul, and other great men were conspicuous by their absence, to the great and oft-expressed regret of the managers of the Show and general public. Mr. Cant was there, but was by no means in his last year's force, and Mr. Davidson also showed very fairly. Mr. Robert Veitch, of Exeter, too, came to the front, and considering how his blooms had been knocked about on the journey (for he was with us) showed very well.

Among the amateurs, Mr. Arkwright, of Hampton Court, Hereford, and the Rev. George Arkwright, of Pencombe, seemed to divide all the best prizes. I managed to get one first prize for twelve blooms of Madame Rothschild, which did the same good office for me last year; but I only mention this in order to introduce the following good thing. A lady was admiring my box of Rothschild, and turned to me with the remark, "You must have a very strong plant of this variety to show so many blooms." Mr. Baker was second for twenty-four singles, but would have shown very much better but for the ill treatment his boxes experienced on the journey.

Of all the places where we show the Rose, Hereford, in my humble opinion, is the best and pleasantest. The Shire Hall is admirably adapted for exhibitions of this kind. It is lofty and well ventilated, the arrangements are all good, and superior to any I have seen. There is not the slightest confusion; your tickets are given you in the form of small adhesive labels, which you fix on your boxes (a red and black number, one showing the class and the other your own number). When your boxes are ready they are taken from the dressing tent by porters to the Shire Hall, and placed in their proper place. You have only to uncover at the last moment, and they are ready for the judges. I believe this is the Leeds system, and if so, we are all indebted to Leeds, for anyone who was present at the Crystal Palace at the last show will know what confusion there was there from want of some such arrangement. Civility, kindness, and hospitality are the rule at Hereford. There is no delivering a few tickets to policemen to give away to their friends as at Bath, while the great horticulturists are ignored; there is no hot and furious contention with policemen there. On your pass ticket you are informed that there will be luncheon ready for you at a certain time, and you have only to present your card to have a most excellent one too. But not only in this way, but in all others is the hospitality of Hereford shown. I had three invitations to houses to stay the night, and my friends the same, and I only wish that we in the west may succeed in starting our Western Counties Rose Show next year, so as to offer an inducement to our Hereford friends to come and see us. I should like to welcome my friend Mr. Bulmer, who so hospitably entertained me; I should like to grasp the hand of that famous rosarian who rules over the King's Acre, and who took me round his beautiful nursery when every moment was precious to him, as on that very day he was staging for Wisbeach.

And oh! what a treat we had at that nursery! Plants! Messrs. Editors, I had never seen plants till I saw his. Roses! I had never known what a Rose was capable of till I saw his Manetti Roses. "To think," said Mr. Baker to me, "to think that you and I have been working for years, and yet we have done nothing—nothing that will bear comparison with this." I never have seen such a sight as those acres of Roses presented, and I fear I may never again. Our friend Cranston was in his might—in his glory. Fisher Holmes was there, shown as large and as perfect as my best Lefebvre; Horace Vernet—but, no, I cannot go on. Suffice it to say that Mr. Cranston had staged the day before for Hereford, and that morning for Wisbeach, and yet he had so many perfect blooms left that we all confessed we had never seen anything in the way of Roses before. Days might profitably have been spent there, and I had only one short hour to give, or I could not have got home that night, and next day I was to show at Frome, and so I was forced to bid adieu to my kind host, but not before he had made me promise to stay with him at the next show. But though I say adieu, the memory of that day will not be effaced from my mind till the blessed time arrives when I can go there again. And now, as I write, the memory of those Roses is present in my mind; the strains of the string band which discoursed such sweet music through the Hall return; the beauty of the cathedral, with its glorious Norman arches, its magnificent rood screen, its sweet-voiced choir singing praises to Him who sends and tends the flowers (His gifts) which we love so well; the genial kindness of friends, the brotherhood, the freemasonry of rosarians, more conspicuously shown surely in Hereford than elsewhere—all this and much more causes the very name of Hereford to sound sweet in my ears, and makes me love the Rose even more than I did before.—JOHN B. M. CAMM.

DISEASED POTATOES IN ORCHARD HOUSES.

I AM glad that our late disagreeable surprise—the finding much of our Potato crop diseased—has attracted the attention of such an experienced observer as Mr. Abbey, and I hasten to say that these Potatoes (see page 40), were planted last October, and fairly ripe by the 15th of April; but as the houses are unheated, and the season ten days late here, the fruit had not set so much as to require syringing to any extent capable of affecting the haulm. Of course shutting-up houses with large borders of Potatoes, and syringing heavily overhead, would not be the best way to ward-off disease just as the tubers were ripening, but it was not the case here. On searching still further I think the manure used was too fresh, a fault which is very common with hasty gardeners; but, after all, why should not

the germs of the disease have been carried in with the old garden soil, which had last season borne good and bad Potatoes? Am I to expect diseased Potatoes in these borders next season; and if so, why?—T. C. BRÉNAU.

SHADES AND SHELTERS.—No. 3.

I have to thank "E. T. B." (see page 15), for adding to my list by bringing forward his flower shade, and others would do a service by making known any well-tried contrivance, as it is not possible for one individual to be acquainted with all that are in use.

I have yet a few illustrations to add, and a few more words to say upon plant shades and shelters.

Fig. 9 is a sketch of a shade for pot and border plants, and its construction may be thus described:—Take two wooden

Fig. 9.

hoops, one about two-thirds smaller than the other, and four straight stakes or deal laths; tack them either inside or outside of the hoops at equal distances apart, the stakes to be cut off flush with the hoop at the top, but at the bottom the hoop may be fastened at some distance from the ground according to the size of the frame. The bottoms of the stakes should be pointed so as to fasten the frame more firmly into the ground. Having the skeleton thus made a covering will suggest itself, which must be of some opaque material—as light thin canvas, or waterproof calico; even paper coverings are not to be despised. The illustration will show that it is a very simple and inexpensive contrivance, and may be easily modified to suit any requirement. For the admission of air the top must not be closed when in use, and whatever covering is used a space of several inches must be left open between it and the ground. It is easy to see that this is a very effectual shade, and useful also for protecting individual plants in bloom from being injured, or, perhaps, destroyed by spring frosts.

I have still another one (figs. 10 and 11), made to protect large plants of Rhododendrons and various other choice spring-flowering plants, or even whole beds of plants. To make it, select a sufficient number of stakes according to the size of the plant, to stand 3 or 4 feet apart, and high enough that when the top is put on it will be a foot or more clear of the shrub to be protected, and the stakes are driven firmly into the ground. A circular frame of wicker-work (fig. 10), made of willows or any other green pliable wood, is put over the top and fastened to the stakes by rope yarn, and as long as there is any danger from frosts this framework is left over the plant, so that when necessary a covering may be put over it, which is generally garden mats or canvas. These shelters (fig. 11), may be constructed of any shape, and are very light and durable if taken proper care of when not in use. To make them is profitable employment for the garden men in winter time, and the materials are inexpensive.

Doubtless the means of shading and sheltering might be beneficially extended to all tender garden crops, as well as plants and flowers, by other means than those described in this article; but when once used they should be constantly applied, for one night's neglect may destroy all previous or even future efforts to save or restore a crop or plant to good health. There is no scarcity of materials for shades and shelters of a temporary kind, it only requires the ingenuity of man to work them up into suitable shapes for use. There are other means of protection which come into the gardener's hands almost ready made, such as common garden mats or thin oiled canvas, which may be cut into convenient widths. Either of these should be more frequently kept in readiness to use when required for protecting wall trees by being hung before them, or standards and espaliers by being thrown over them, or even to throw flat on the earth to protect tender plants just coming above the surface, and for sheltering plants from wind, rain, and sun. A common plan of mine is to tie a light pole to each side of a dozen or two of the mats or canvas, and they are always ready to stretch over anything requiring extra protection, and also for earth or turf pits that have no other covering.

Although shading and sheltering by mechanical contrivances is important to the gardener, there are other means by which the requisite shade and shelter may be obtained. I allude to natural means by the planting of hedges, and the protection afforded under the branches of trees, &c. The plant-grower, in however small a way he may be, needs the cool refreshing shade of trees and hedges for the subjects of his care, and in places where the glass accommodation is small, it becomes necessary to clear the houses of plants in order to use them for some other purpose; therefore, wherever it is practicable, a

Fig. 10.

Fig. 11.

suitable-sized spot should be selected, and hedges planted at different angles, backed-up by taller hedges on the north and south sides, and, perhaps, also on the west side. Plants may then be placed in positions to receive either the morning or afternoon sun, or both, or none at all, as occasion may require. The whole should have a firm bottom covered with coal ashes to keep down worms. I need hardly mention, that those plants standing in the sun must have their pots plunged in the ashes, as no pot containing a well-rooted plant can be exposed to the sun without injury.

It may be asked, What is the best kind of plant for hedges for such a purpose? I may remark, that the common Yew makes a good hedge, or even Box, but both are of very slow growth. The common Privet is frequently planted, as also the Hornbeam and common Laurel, as being of much quicker growth; then there are Junipers and Thujas, which would be more uncommon though excellent for the purpose; in fact, there is ample choice of plants, and the above are mostly ever-green, which I should consider an advantage. Those who have such a place as I have described can fully realise the benefit derived from its shade and shelter, but those who have not cannot become fully alive to its value until they possess one.—THOMAS RECORD.

LITTLE HEATH MELON.

LITTLE Heath Melon is spherical or round, and flattened at the ends, slightly ribbed, and when not coarsely grown finely netted; altogether it is a fine-looking fruit. The flesh is thick very melting, juicy, and well flavoured, and in colour bright red. Rind thin. The plant has a good hardy constitution, is a free setter, and will succeed in a frame with a small amount of bottom heat to give it a start. It is not a gross grower; on the contrary, it is rather slender, but very free both in fruiting and growth to support fruit.

I sowed three seeds March 3rd, and planted out the seedlings

on March 31st, one plant under each light of a three-light frame. They grew and set without a drawback, on June 24th I cut the first ripe fruit, and within a fortnight had cut a dozen fruit of an average weight of 4 to 4½ lbs. I could have had them larger, but size in Melons, as in many other things, is obtained at the expense of flavour. Some fruits weighed nearly 6 lbs., although the plants were stinted of water. The plants are good for another crop. Little Heath will grow to a large size, no doubt, if well supplied with water, and slightly shaded from bright sun. If cut before it is very ripe the fruit will keep for a fortnight or more; indeed, it has no superior in keeping properties that I know, except in the old and I believe extinct Cabul Melon, which I have known kept for weeks. I should be glad of a few seeds of the Cabul, through the Editors of this Journal, if it is at present in cultivation. It is elliptical in shape, yellow outside when ripe, with a greenish white flesh. Little Heath Melon is the true Beechwood, with a fruit precisely similar, and not so strong a vine, and the flesh is scarlet. It will be extensively grown, and be everybody's favourite scarlet-fleshed Melon.—G. ABBEY.

COLAX JUGOSUS.

WHAT is Colax jugosus? This question has been asked me by many amateur Orchid-growers during the past season, and a few words respecting it will, perhaps, not be considered out of place in the pages of the Journal, for the benefit of those amateurs who may contemplate adding it to their collections.

Colax, then, is a genus very nearly allied to Maxillaria—indeed, so closely, that it is questionable if the differences are really sufficient to warrant its separation, the chief feature which has given rise to its elevation to generic rank being its peculiarly long-pointed glandless caudicle; but as the genus is acknowledged and upheld by the highest authorities, we must accept it as being sufficiently distinct.

Turning, however, to this plant horticulturally, Colax jugosus is a plant of dwarf compact habit, producing flowers of great beauty, and is well deserving a place in every amateur's collection, no matter how limited the accommodation. The full height of the plant seldom exceeds 12 inches. The pseudo-bulbs are smooth, somewhat ovate, and about 3 inches in length; from these it produces dark green leaves both from the top and base; the leaves are usually from 6 to 8 inches long, and about 1½ inch, or from that to 2 inches, broad. The scape springs from the base of the pseudo-bulb, and is clothed with large imbricating scales, bearing upon the top sometimes three, but more frequently two, somewhat globose flowers, which when expanded are about 2 inches in diameter. The sepals are very broad—indeed, almost round, and soft cream-coloured; the petals are also very broad, but more oblong than the sepals, and their colour is pure white, beautifully marked with transverse bands of rich dark purple; the lip is small, furrowed, and velvety; the side lobes white striped with dotted lines of deep purple, whilst the semicircular front lobe is also white, dotted and striped with rich velvety purple. By this description it will be seen that Colax jugosus is a little gem, and a plant that is not likely to outgrow the convenience of even the smallest stove; and when I add that its flowers are produced very freely during April and May, it must, I think, be acknowledged worthy of every attention from all lovers of the chaste and beautiful.

With a few words upon its culture I will bring these brief notes to a close. Until quite recently Colax jugosus has been extremely rare and so little heard of, that, as its name is out of the usual stereotyped genera, it having made its appearance with some frequency at the public sales during the past year, it has come upon amateurs as a surprise. Many Orchid-growers imagine it to be a cool-country plant, and to some extent it is so, but it likes a little more heat than the majority of Odontoglossums, and I have found it succeed best when treated in every respect the same as *Cattleya Mossie*, and, like the last-named plant, it is a native of Brazil.—EXPERIO CREDE.

THE NEW STRAWBERRY DWARF TOMATO.

We are perfectly willing to admit that the Strawberry Tomato is the same as *Physalis edulis*, but we are not aware that *Physalis edulis* has been used, or at all events of late years, as a vegetable. The name "Strawberry" and the description were taken from American catalogues of repute; the wholesale price 1s. per oz., and the retail price 6d. per packet, being in accordance with the current value of *Physalis edulis*. It is

not the custom with the majority of the trade to put the scientific name to vegetables, and we were justified in putting "new" against it on account of the novel application of an almost unknown esculent. Wherein, therefore, consists the deception? In the American catalogues we had observed a slightly increased charge was made for this novelty; we, however, refrained from charging more than the current value of *Physalis edulis*. If we had put the scientific name of *Physalis edulis*, probably your correspondent would then have seen a fraud in our not calling it Cape Gooseberry. Some people see deceptions where deception is not intended.—INTRODUCERS.

EXHIBITION FRAUDS.

I ENCLOSE a letter which reached me yesterday, and which I have resolved to hand to you to deal with as you may think fit. It has long been whispered that prizetaking plants and flowers are not always and altogether the property of the exhibitors; and some exhibitors have been charged with valuing the artifice of beating an opponent by borrowing, more than by the skill required to beat him by cultivating. As to the honour of winning a prize by the exercise of industry and skill, honour, not being a marketable commodity, is never thought of, or reckoned as nothing by such people. It has long seemed to me that some steps should be taken to stop these practices, or the morality of our flower shows will soon sink to the level of the ordinary race-course or the low country fair.—WILLIAM PAUL, *Waltham Cross, London, N.*

"July 21, 1873.

"To W. PAUL.

"Sir,—Would you be kind enough to send me word by return of post if you can supply me with twelve cut Roses about the last week in August, to be shown in a stand of three? Please send your terms for the same, and oblige yours—H. WALTON, *Carr Mill Terrace, Haslingden, Lancashire.*"

APPLICATION OF NITRATE OF SODA TO THE GLADIOLUS.

"D., Deal," asks, how and in what proportion to use the nitrate of soda? Perhaps the best answer I can give is, Much as you would apply guano to an Onion bed by sowing, or dissolved in water, or by mixing it with the soil during the winter turning. I do not think it is so powerful as some people seem to imagine. I hope that I am not understood to mean that it will entirely eradicate the disease, but rather that by its use I avoid wireworm, and grow the Gladiolus more gross than without it. I generally use as much as I can lift with one hand in about six gallons of water.

I am afraid we hear far too much about well-decomposed manure. This year my Gladiolus bulbs are amongst new cow manure, to which I strongly advise all your readers to give a trial, especially if their soil is light. They will then avoid its being washed and dried, and will never afterwards have reason to regret using it.

Your readers will form some idea of my love for the Gladiolus when I mention that on the 15th inst. I was to be found some 350 miles from home examining Mr. Banks's collection, for the sake of information and comparison. I am glad that I then found many as good, and growing as robustly as heart could desire; but, unfortunately, also, many were just as sickly-looking, whole beds going off together—in fact, worse than I had ever previously beheld them. I should gladly have seen "D." of Deal's at the same time, but circumstances did not allow of my doing so.

Two things in particular, in passing over that eighty-two miles of line from London to Deal, which made a deep impression on my mind, were the poverty-stricken appearance of the land on each side of the rail, and the fact of seeing men backing with scythes at old, dried, brown meadows—strangely ripe to what we cut grass in the north—and never in all that distance seeing one mowing machine. My wonder ever after shall be not that the south-country farm labourer is poorly paid, but that his employer is able to recompense him at all, seeing that the latter has to compete with such immeasurably superior arrangements. We call out—and justly so in some places—about the evil effects of the Game Laws; pray let us in future carry on a war of extermination against Nettles, Dockes, Thistles, Poppies, and other such impoverishing weeds, and the result may be a national blessing. My impression, from close observation during my long journey, was that our cultivated lands on the average do not yield half the produce that

they are capable of affording, and in some disgraceful instances not a tenth portion. Men appear to be satisfied with doing the work of only women in the south, or what is more correct, being human machines, seeming entirely to forget that this is an age of progress, when man's place is rather to cease from drudgery, to direct, and to see that the inventions of wise men are properly applied in more effectual methods of cultivation. —J. WITHERSPOON, *Chester-le-Street*.

IMPLEMENTS, STRUCTURES, AND APPLIANCES.

AT THE ROYAL HORTICULTURAL SOCIETY'S BATH SHOW.

We have hitherto omitted any notes on the implements, horticultural structures, and appliances at the Bath Show, from want of space, and also because our notes on the houses, boilers, &c., exhibited last year at Birmingham were so full that there is not much to add, and there were very few novelties exhibited at Bath that had not been shown at Birmingham.

There was a good array at Bath of glass houses by Mr. Parham, of Northgate Works, Bath; Wheeler, Humphreys, & Co., Nottingham; T. G. Messenger, of Loughborough; T. H. Dennis and Co., Anchor Works, Chelmsford; Cranston & Luck, Birmingham; Tuck & Pike, City Metal Works, Bath; W. H. Lascelles, Bunhill Row, London; Mr. E. Lloyd, Grantham; N. Voice, Handcross, Surrey; Mr. Ormson, King's Road, Chelsea; Mr. Boulton, Norwich; Mr. M. E. Horley, Toddington, Dunstable; Mr. Rendle, and others. Many of these exhibited also specimens of hand-lights, portable garden frames with loose sheets of glass, &c. The prize house of last year was not shown, nor did we see Mr. Ayres' imperishable glass and iron houses.

Those especially worthy of notice this year were a patent glass orchard house of Mr. Dennis's, where the whole of the glass of the roof is made to open upwards and outwards by means of a rack and pinion screw attached to levers, so that at any time the trees may be exposed to the full action of the outer air and rain, or protected at pleasure. The construction is such that it is a tenant's building, removable at will, having no permanent brick foundations, but resting on iron posts or pillars with wide flanges. The construction is light and strong, and displays considerable ingenuity; the cost is comparatively moderate.

Messrs. Cranston & Luck showed some good moveable frames for protecting wall trees, running on longitudinal iron rods on rollers, simple in construction, with a protecting eave, and which could be fixed to any existing wall. The lights, made something like large Melon or Cucumber-frame lights, are easily moved, so as to get to the trees for pruning or syringing, tying, nailing, &c., the ventilation easily arranged, and on the whole there was much to recommend.

Messrs. Cranston & Luck's amateurs' and gardeners' houses, with their system of ventilation, are so well known that we need not describe them.

In the other exhibits of glass houses we did not notice much novelty, although the glass was fixed in every possible different way—with putty and without putty, with laps and without laps. It is high time, we think, that patents should not be given for slight alterations in the method of fastening glass or of ventilation, or peculiar form of grooves, &c., unless there is manifest novelty or improvement. Patents are intended to stimulate invention and to protect the inventor, not to hinder invention and hamper development of thought in the public, and we maintain—where nearly every possible form of construction in iron and wood, with variations in the form of ventilation, or shape of spar, or form of groove, and the other thousand-and-one minor variations which we meet with are to be found—no further patents should be granted, but let the buildings rest on their own merits. The public will not be slow to discern what is practical, what is simple, and what is feasible, as against the unpractical, complex, and useless.

There was a great variety of moveable frames, and ground vinerias, and amongst these we are inclined to give the palm for cheapness, simplicity, and durability to Mr. Horley, though the construction of his larger house was faulty.

Mr. Parham showed some exceedingly good wall glass copings, that we preferred to his glass walls, which were made with too light iron, and which we do not think calculated to stand strong winds, though they might answer very well in protected situations.

Messrs. Pike & Tuck showed a somewhat elaborate plan of fixing glass with brass pin and nut, and lead clip, the method ingenious, but unnecessary. We quite agree with those who recommend for an ordinary stove or greenhouse, glass bedded in putty, but having no outside putty, the glass being fastened with two tees, and the putty removed level. We have seen this most effectual at Mr. W. Paul's, Waltham Cross, and elsewhere; and secondly, for glass frames, ordinary bedding-out houses, lights of all kinds, glass pushed up in a groove without putty or lap will answer every purpose, and it merely requires

fastening in its place with an iron pin or lead clip. A fruitful source of error is found in the patent ventilation of side-lights when, by means of ratchet and screw, the whole of the lights move together, and, as is generally the case, a draught is let in upon all the plants on the staging. How long will it be before people learn that ventilation means change and circulation of air, not cold draughts, and that the best ventilation is under the stages in the walls, with proper top ventilation along the apex of the roof, the glass not being made too air-tight?

Passing on from the glass structures we will take next the methods of heating those structures. Our notes on the boilers last year were so full that we need not say much on this score, as we see no reason whatever to alter the conclusions we came to then.

The best upright tubular boiler shown this year was Harlow's, the best horizontal tubular Mr. Dennis's, and the best spiral Mr. Deard's. The medal boiler of last year was not exhibited, but the Witley Court boiler, which was nearest it in construction, was there, and for a powerful useful boiler of the modified saddle form we know no better; and we still adhere to our opinion with regard to Mr. Deard's spiral boiler, which must, from its construction, have a uniform and rapid circulation. We must, at the risk of being accused of repetition, again say that no unnecessary impediment should be placed to the circulation of water by complicated pipes, small junctions, rapid curves, &c. The motive power in heated water is exceedingly feeble, and the best boiler is that which extracts the greatest amount of heat from the fuel, and has the most rapid and easy circulation, with least difference of temperature between the flow and return.

We forgot among the modified forms of saddle to name one of Mr. Ormson's, and also a combination of the saddle with horizontal pipes from Mr. Lloyd, of Grantham, which we should like to see tried, and which appears to be a very promising one.

While on the subject of heating we wish to pass high commendation on the model shown by Mr. Cowan for utilising the heat of a small lime kiln to heat a boiler. Where chalk or limestone is near or on the property, the lime is very nearly capable of repaying the cost of outlay and attention; indeed, as Mr. Cowan continues to improve and modify his present invention by economising still more the heat of the lower part of his furnace by using hollow bricks, we think that the value of the lime may be made to repay the whole of the cost. It is, of course, especially suitable for a large range of houses in constant use; but with the present price of fuel anything that can make coal answer a double purpose is especially valuable. The form of boiler adopted by Mr. Cowan is a very good one, and better than the tubular. Exception has been made as to the necessity for a great depth of stokehole, but this is rather imaginary, we conceive, than otherwise. When 13 or 14 feet can be found for the kiln, it is better to have it underground, as it is thus more easily hidden; but so long as a rise is once given to the flow pipe, it may then be made to descend, and though there would be a slight waste of heat if the pipes had to descend in the outer heating chamber previous to entering the houses, yet there is nothing practically to prevent such a system, though not the best. We publish an extract from Mr. Cowan's introductory remarks on his system. We may add, that even where lime is not an immediate product of the district, it will generally pay for its cartage.

"My first idea was to try turf or peat. I fancied that by having a good supply of it at hand, and keeping a person almost in constant attendance upon the fires, I might in some way or other (not very clear to myself, I confess) get through the season. But the continuous wet weather which prevailed all through last autumn prevented me from accomplishing my object by this means. There seemed to be nothing for it but coal at nearly 40s. per ton, or to let everything rest until the natural heat of spring called them to action, when, fortunately, the idea presented itself of combining a lime kiln with a hot-water apparatus. This plan seemed at first to be beset with a considerable amount of difficulty; but, nevertheless, I had strong hopes from the first that it would prove to be a solution of my difficulties. As the work proceeded, my faith in the experiment grew stronger, and it required only a short trial to prove that we would get heat, and plenty of it, free of cost.

"The first apparatus erected heated only one-half of our houses, and we immediately set to work and took up a boiler which had not been long set, and erected another apparatus such as the first, and for months past both have been doing their work in the most satisfactory manner possible.

"The lime produced is of good quality, and the quantity is quite sufficient to pay all expenses. The appearance of the apparatus which has been in keeping with a well-dressed garden, and there is no disagreeable smell, nor anything else offensive about it, to prevent even the most fastidious from adopting it. All who have seen our two kilns have pronounced them to be rather ornamental than otherwise.

"The proper fuel to use is anthracite coal or culm, from which there is no smoke, or, at least, so little as not to be perceptible; consequently there need be no fear of anything being done in that way by their adoption.

"The management of the apparatus is simple, and easily understood by any ordinary workman. One of the two kilns which we have at work has never been attended to more than once during twenty-four hours, and during that time the heat is kept up constantly and powerfully, and in no case need they receive attention more than twice during that period. Those who have experienced the great amount of trouble which many furnaces cause by the constant attendance which they require, will at once understand the benefit to be derived from having an apparatus which can be left with perfect safety for twenty-four hours, not once or twice, but constantly.

"I can also, at a very trifling extra expense, fit up this apparatus so that the houses can be kept quite cool, while the kiln is allowed to continue burning, the heat being shut off or on at pleasure, according to the necessity of the time.

"The production of good lime is, on most noblemen's and gentlemen's places, a matter of considerable importance, and it ought to be considered an advantage to be able to produce it with the fuel which would otherwise be lost in heating the garden structures. To nurserymen the matter ought to be of still more importance, as the present rate of fuel must be a heavy tax upon them.

"I am fully of opinion that this system will prove valuable, not only where limestone is plentiful, but also where it is not near at hand. Lime must always be had; and it will be found more advantageous to pay for the carriage of the raw material than for made lime, especially by sea, as lime is a dangerous cargo which few shippers are willing to undertake; and it must be recollected that lime is always more valuable in districts where neither limestone nor chalk are found—so that the cost of carriage is in a great degree compensated for by the local value of the lime produced."

We need not say much about the other exhibits. Mr. Chapman showed his well-known flower-boxes and exhibition-cases, with boxes for the transmission of fruit, game, &c.; Messrs. Follows & Bates a selection of their Anglo-American mowing machine, which, in our experience, is *facile princeps* of all other mowing machines, and this may be saying a good deal; Mr. Pinnell, of Bath, a most absurd watering pot, with a syphon to water plants overhead. We should much like to see an old-fashioned gardener's face if his master had made him a present of one and told him to use it. We must not, however, pass over a very beautiful collection of ornamental pottery, shown by Mr. Matthews, of Weston-super-Mare; all the work exceedingly good, both the ornamental and useful, and we can confidently recommend any persons in want of garden pots and vases, &c., to try some. We saw, by the way, that the same enterprising firm had exhibited a collection at the Hull Show, and we hope that, from the many thousand visitors who attended, there was custom enough to repay the venture.

With these few remarks we will conclude. We do not think the implements, as a rule, well represented, and we hope if next year see the Society's Show at Sheffield that that branch may be better represented than it was at Bath.

WALES AND WELSHMEN.—No. 2.

It is written that there are in England more *Smiths* than of any other two names added together, but in this Principality *Jones* is the patronymic far in excess of any three patronymics combined. How the thousand-and-one Joneses in a Welsh town are discriminated is beyond my astuteness. It might have been by leaving out one name when, as Camden writes, "in the time of King Henry the VIIIth, an ancient worshipful gentleman of Wales being called at the panel of jurie by the name of 'Thomas Ap William, Ap Thomas, Ap Richard, Ap Hoel, Ap Evan Vaughan, Ap Jones,' was advised by the Judge to abandon that old manner; whereupon he after called himself *Moston*, according to the name of his principall house." It may be useful to observe that "Ap" means "son of." Then, in the names of places the tautology is bewildering; there are 458 the names of which begin with *Llan*, and many have the same affix; so when I had occasion to inquire which *Llanfair* was alluded to, the still more bewildering reply was, "Oh! *Llanfair pell-g-gwynyll*." So, also, there are more than fifty places the first syllable of the names of which is *Pen*, and that invariably indicates that it is on a hill or headland. Knowing this, and wishing for a far look-out to sea, as well as to see the ruins of, perhaps, the most ancient of the Welsh religious foundations, I wended my way to Penmon Priory; for it was founded in the sixth century.

I could scribble about it for "an hour by Beaumaris clock," but it would be scribble not desirable for your pages, and I will but note that this, like all other monastic institutions of the olden time, bears testimony that the friars well knew that feasting is an essential as well as fasting, and that feasting needs a well-supplied treasury. There is no feasting without good water, and here is as bright a spring of it as ever flowed perpetually. So the Friars enclosed it, built a little chapel over it, placed stone seats around it, made little recesses in its walls in which offerings might be deposited, and small benefit was to be expected to him or her who did not deposit in those recesses—they were the saving banks, both of the friars and the patients—for the spring was named "The Holy Well of Saint Seinol," and those who drank of its water and deposited (that was essential) were to be cleansed of any disorder that afflicted them. That well and all its surroundings remain and bear testimony that excellent water and contributions were secured to the Priory; for this, like all holy wells, was flocked to, and was sanitary for the same reason that Beaumaris is sanitary now—there is a change of scene, change of occupations, and sea-breezes.

Excellent water is but an essential in preparing the more savoury contributions to a feast, but the sea is within bow-shot, and its endless supplies put all safe for days of abstinence from flesh; and then Puffins Island almost joins the Priory lands, and the flocks of birds which gave it its name were the most acceptable produce with which Friars could be endowed, for they are aquatic birds, which a wise Pope, infallible in this, decreed might be eaten on fish days, because, being aquatic, they partake of the nature of fish.

Next I will mention their noble Dovecote, a drawing of which from a photographer* accompanies these notes. Its

walls are very ancient, probably coeval with the Priory's re-enclosure in the thirteenth century, but the cupola which surmounts them is not older than the fifteenth century. It is quadrangular, each side being 22 feet long and 20 feet high. There are eighteen rows of nest-holes on each side, and in each row fourteen nest-holes, so, deducting the spaces for window and doorway, there is accommodation for nearly five hundred pairs of pigeons. In the centre is a circular alighting-pillar, 10 feet high and 2 feet diameter, with projections to ascend it. On the top of this pillar the pigeons alighted as they descended from or ascended to the opening in the roof.

There are near the Priory some of the largest and oldest Whitethorn trees I ever saw; they are many in number, about 30 feet high, and their stems nearly 6 feet in girth. It is easy to conclude where the orchard and garden were, and although we can trace no remains of their tenants, we do know one of the vegetables afforded abundantly to the holy fathers, though they were not pottage men, for theirs was not a vegetarian age.

The vegetable I allude to is the Alisander—Alexanders, as gardeners in the olden time called it—*Smyrnium Olusatrum*. Unblanched, it is aromatic; blanched and cooked, it is not unlike Celery. Down to a comparatively recent period sailors belonging to this coast consumed it largely as an antiscorbutic, and the supply was inexhaustible, for it grows wild and abundantly on the south-west end of Puffins Island. Its Welsh name is *Dulys cyfredin*, intimating how much it is a requisite; but it is no longer cultivated here. Sea Samphire, *Crithmum maritimum*, was also at hand on the rocks of the same island, and was known to the friars by the name of *Corn Carw y mor* (the Stag's-horn of the Sea). The holy fathers knew how to pickle it, and so they did the young puffins, but neither of those relishes seem now in request. Archbishop Baldwin, writing some seven centuries since, mentions Puffins Island as *Ynys Ilenach* (Isle of Erudition), and states that "it is inhabited by hermits, living by manual labour and serving God. If any discord arises among them all their provisions are devoured and infected by small white mice, with which the island abounds, but when the discord ceases they are no longer molested. No woman is suffered to enter the island." No doubt they were the cause of the discord and the white mice.

In a future communication I hope to be able to write more about the gardening of Anglesea; but Baron Hill, Nant, Plas

* The photograph was taken by Mr. J. W. Ambrose, Photographer, Beaumaris, to whose intelligence as an artist and lover of literature I am much indebted.

Newydd, and probably some other residences, have gardens that will each require a separate notice.—G.

FLOWERS FOR OUR BORDERS.—No. 12.

THUNBERGIA ALATA.—WING-PETIOLED THUNBERGIA.

THUNBERGIA ALATA and its varieties have, from the date of their introduction, taken high rank among popular annuals, a position which they still retain, notwithstanding the numerous competitors for public favour which the seedsmen's lists now comprise. This popularity is well merited, not only on account of their elegant flowers and foliage, but for their great utility as dwarf climbers. They also claim the attention of the amateur for the curious structure of those parts of the blossom more immediately concerned, and other features, to which a brief reference may be made.

In commencing our examination of the flower, we must beware of confounding the two large bracts by which the corolla is enveloped before its expansion with the true calyx, which is very small, and only perceptible upon a close inspection. If the two bracts be pulled aside, twelve minute teeth will be observed clasping the base of the tube of the corolla; and after the blossom has fallen, these teeth embrace the ovary so closely that the uninitiated observer would easily overlook them altogether, and imagine the more conspicuous bracts to be the calyx. If one of the satiny corollas be opened, there will be discovered within four rather short stamens, each terminated by a highly curious fringed or bearded anther. The office this fringe performs—and that it has one we may be assured—it is somewhat difficult to guess; it perhaps serves to retain the pollen after its emission from the anther until the stigma is fit for its reception, for it does sometimes occur that the pollen is mature before the stigma is sufficiently advanced to receive it, and if in this case no provision were made for the retention of the fertilising particles, they would be scattered before the impregnation of the ovules could be effected. Decidedly the most interesting part of the flower is the slender curved style with its double stigma. This organ, destined for the reception of the pollen, has, in addition to its small terminal cavity, a beautifully delicate shell-like lateral stigma of a larger size. Both of them are, however, so minute that in order fully to appreciate their exquisite finish a microscopic examination will be requisite, but a Stanhope lens of moderate power will be all that is necessary. There can be no doubt that both of these appendages to the style perform the same function, for if the terminal stigma be cut off before the pollen is ripe, seeds will nevertheless be matured, which proves satisfactorily that in this case the pollen must have been conveyed to the ovules through the medium of the beautiful organ to which we have referred. Each of the seed-vessels contains four hard cup-shaped seeds.

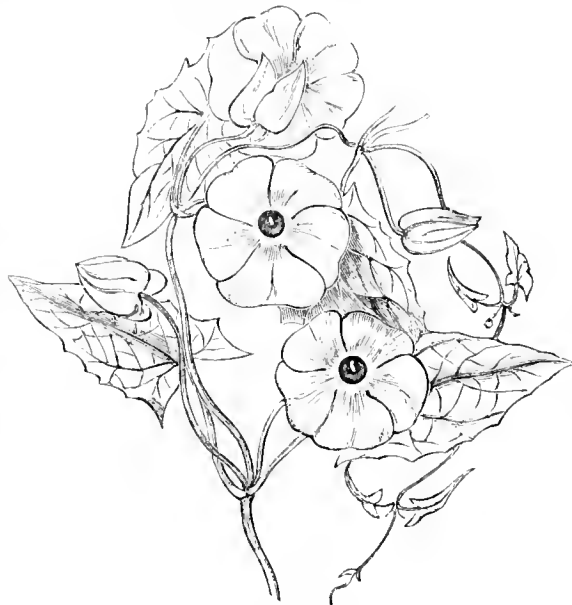

It will be remarked that the petioles have a leafy edge, or are, botanically speaking, winged, a circumstance by which *alata* and all its varieties are easily distinguished from other species.

The flowers of the typical *Thunbergia alata* are of a buff colour with a deep rich purplish-black tube or throat; in the variety *alba* the limb of the corolla is pure white; in *aurantiaca*, one of the handsomest, the limb is orange; in *sulphurea* of a yellowish buff; and in *Fryerii* both limb and throat are of a uniform orange colour.

All these are of easy cultivation, either in pots for the window or for ornamenting the flower garden during the summer. The seeds require to be sown in spring upon a hotbed, and we have sometimes found it advantageous to soak them for three or four hours previously in tepid water. A light vegetable soil, composed of leaf mould or very old and thoroughly decomposed manure, with a third of any good garden soil, will form a suitable mixture in which to sow the seeds. With a good bottom heat of 75 the seedlings will soon appear above ground, and, as the roots descend deeply into the soil of the pot, the young plants will be best potted-off separately as soon as they have made one pair of leaves in addition to the seed-lobes. In the whole of their after-treatment a free, open, vegetable soil must be used. If intended as a window ornament, as soon as the small pots are filled with roots the plants should be shifted to one at least 5 or 6 inches in diameter, if a fine specimen is desired; and an important point to be attended to is, that the leading shoot must be pinched off when it is a few inches long; and this operation must be repeated as often as the laterals threaten to outgrow their trellis, by which means a multitude of side shoots will be produced, and the plants be restrained

within moderate bounds. All the varieties of *alata* produce an abundance of flowers for two or three months in succession; and when covering, as they can easily be made to do, a wire trellis 3 feet in diameter, more striking objects cannot well be imagined.

To preserve the delicate green tint of the foliage, the plant should be shaded from the direct rays of the sun during the hottest part of the day; and as the whole of the *Thunbergias* are extremely liable to the attacks of the minute insect popularly termed the red spider, the plant should be frequently sprinkled or syringed with water. During this operation the pot should be turned on its side; the soil will thus be preserved from too much moisture, and the application of the water can be more effectually carried out. If the plant is kept in a dry hot atmosphere, and the precaution of syringing be neglected, the leaves will speedily lose their rich green hue and assume a pale spotted appearance, and upon a close examination the little pests to which we have alluded will be found in vast numbers upon all parts of the plant, chiefly, however, on the under surface of the foliage.

Thunbergia alata alba.

When cultivated out-doors a shady situation and rich light soil must be chosen, as in a hot, dry, exposed locality they will not succeed. They may be grown against a wall with a suitable trellis, or allowed to trail; but in this case the ground should be covered with a few small bushes, which the plants will quickly conceal. A very pretty effect may be produced by planting several specimens in a small bed, and training them over a few willow rods bent across from side to side. In short, in almost any situation partially shaded, and where proper support can be given to their twining stems, the *Thunbergias* will be found among the most ornamental of the summer occupants of the flower garden.

The species of *Thunbergia* are not very numerous, but include several splendid plants, nearly all of which are inhabitants of the stove. The most remarkable are *chrysoptera* from Sierra Leone, with the limb of the flower of a rich purple and the throat of a golden yellow; *fragrans* with white flowers; *Harrisii* and *laurifolia* with very large blue flowers; and *Hawtayneana* with scarlet flowers, all from various parts of the East Indies. The plant formerly known as *T. coccinea*, also a stove species, is now placed in the genus *Hexacentris*.—W. THOMPSON, Ipswich.—(*English Flower Garden, Revised by the Author.*)

MESSRS. SUTTON & SONS' TRIAL FARM, READING.

TRAVELLING down the Great Western Railway the other day I found that as we neared Reading there was a general rush to the windows of the left side, and it turned out that the

stampede was caused by the knowledge that the annuals on Messrs. Suttons' seed farm were then in full bloom; and when, in common with my fellow travellers, I looked on the sight presented to our view, I did not wonder at the movement, nor at what I was told afterwards—that when Her Most Gracious Majesty was travelling on the same line the other day, she drew up the blinds to gaze on it. As it presented itself to the view one saw all the colours of the rainbow were there, and more too—gorgeous yellows, glowing crimson, brilliant scarlet, soft pinks, dazzling oranges—yea, even deepest maroons and pure whites were there, and as my destination was Reading, I promised myself the pleasure of looking at them in detail. This I did on the following morning, and found that most of this brilliant effect was occasioned by the annuals, which are many of them so easily managed, but when grown, too often, alas! sadly neglected. I spent then a couple of hours in the trial grounds, and think that perhaps a few notes of what I saw may be acceptable to the many readers of the Journal to whom Messrs. Sutton are so well known by name. Here let me say that annuals do not receive even from those who profess to grow them that care they ought to have. If, instead of sowing them in patches, and then leaving them to take their chance, they were thinned-out so as to leave each plant separate, and so give them a better chance of doing well, and if more care were taken with the soil, better results would be achieved.

The utmost care is taken with those seeds whence supplies are taken for their customers by the Messrs. Sutton, while those grown for them by growers are severely tested in these trial grounds. All "rogues," as false plants are called, are carefully weeded-out, and only those perfectly true retained for seed; it is by this means that the correctness which is so essential a part of such a business as that of Messrs. Sutton can be obtained.

Amongst the most showy and useful of annuals are the various varieties of Tom Thumb *Tropaeolum*, of which there were here several distinct and beautiful kinds. Scarlet Tom Thumb was most brilliant, and as all the plants were regular, nothing could be more beautiful than this large piece. Then there was the crimson, not so brilliant, but still very handsome, the Rose Tom Thumb of a pleasing soft shade of colour. *Carulea nana*, which has a very faint *soupeon* of what may by euphony be called blue, as in Blue Bell *Pelargonium*, but very misleading to those who expect to see anything decided in it. King of Crimsons is another very fine variety, with deep-coloured foliage and brilliant scarlet flowers, yellow-spotted, very bright in colour.

Of the old favourite Sweet William there was a very fine patch of various shades of colour, and with large well-formed flowers, reminding me of Hunt's strain of what he called Auricle-eyed Sweet William. And who can describe the glorious colours in the large piece of Poppies from deepest purple, almost black, down through all the gradations of red, rose, pink, and scarlet, to blush and then pure white? *Eutoca viscidula* was very fine, its intense deep blue and its profusion of bloom making it a very pleasing annual. I wonder that in large places, where many a piece of ground suitable for hardly anything else might be found, Poppies are not more grown. These were past their prime, but still a large number remained in bloom to bear witness to their excellence.

In *Leptosiphons* I particularly noticed in large quantity:—*Rosens*, a very beautiful and dwarf species, which cannot fail to be a general favourite; hybrids, which is very suitable for rockwork (of various colours); and *densiflorus*, a fine lilac. Amongst the showy *Lupinus* there were *Lupinus subcarneus*, a beautiful ultramarine blue; *atrococcineus*, brilliant scarlet and white; while lovely pieces of the minor *Convolvulus*, *Batonia aurea*, *Amaranthus atro-purpureus* with its dark handsome-looking foliage afforded admirable contrasts of colour. *Godetia Whitneyi*, one of the more recent introductions of Mr. Thompson, of Ipswich, was there in large quantities, and exceedingly beautiful it is. Of the *Clarkias* there were many varieties, especially of the *integripetala* section, such as *alba* and *marginata*, and they are a very great improvement on the older *pulehiella*. *Collinsia bicolor* was nearly over, but still good. *Erysinum arkansanum*, a showy yellow flower, a different shade from the older *Peroffskianum*, was always very good. Of the many varieties of *Candytuft* the sweet-scented was, perhaps, the most interesting; while the beds of double-white *Chrysanthemum* were exceedingly good, although difficult to keep true. But time and space would fail me were I to enumerate all the various beauties that were here displayed. Enough has, however, been said to show that it was a sight well worth

seeing, and gave abundant evidence of the care bestowed by this firm in keeping their seeds select, and thus maintaining the confidence of their customers.—VOYAGER.

PRUNELLA OPTIMA.

PERHAPS there is nothing more damaging to the reputation of a plant than giving it a higher character than it deserves. Many years ago an instance of this kind occurred in the case of *Plumbago Larpentie*, which was ushered in with a flourish of trumpets, and great was the disappointment created amongst the majority of its buyers—so great, indeed, that it is questionable at the present day if there are as many plants now in the hands of growers as were sent out from the nursery that first held the stock, and yet the plant was after all not without its merits. The fact was, it was extolled so much that those who bought it, not finding it possessed of all the recommendations it was reported to have, repudiated it before making themselves acquainted with its real merits. Other instances might be named of a like kind; but it is more pleasing to turn to those of an opposite character, and such are plentiful enough, in which a really good plant has been sent out without any fuss or parade, and its real merits not fairly recognised until a year or two afterwards. An instance of this was *Geranium Mrs. Pollock*, which, if my memory is right, was sent out with not half the flourish which accompanied many of its successors, and I am not certain but that this variety holds as respectable a position now in most flower gardens as any of its fashionable offspring.

My purpose is not to speak of *Tricolor Geraniums*, but of hardy herbaceous plants, and if the good properties of *Plumbago Larpentie* were unduly set forth, there is another plant of more recent date that has been quietly making its way without any such help. This is *Prunella optima*, a dwarf-growing herbaceous plant of great beauty, which I think is not sufficiently known to the admirers of such things. I am not certain what country it hails from, but it is a credit to wherever its early home has been. Akin to the *Lamium*, it is of dwarfer habit than the best form of *L. maculatum*, or its fashionable still-more-variegated offspring; for this *Prunella* is not more than 6 or 8 inches high, and as a plant very compact, with upright flower stems, each supporting a globular head of its curiously incurved flowers tinted in two or three colours; but, as a whole, furnishing a sort of combination of red and violet, while the individual heads are large and so numerous on a healthy plant as almost to conceal it. It is also perfectly hardy, and I have not found it at all particular as to site. I need hardly say that well-established plants flower much better than newly-planted ones, but it will bear as rough treatment as anything I know of, and still do well. Its habit being of a somewhat spreading character—*i.e.*, its shoots leaning towards the ground and striking root as they touch it, propagation is easy; at the same time it is not a rambler like some of the *Veronicas*. On the contrary, it is as easily kept in a line as a Primrose, and occupies no more space in width. It flowers in June, therefore too late for spring bedding, but the admirer of the herbaceous border, and those who like now and then to vary their edgings of hardy plants, and may have in some degree become tired of *Viola cornuta*, should try this plant. It is not quite so tall, is widely different in colour, but is equally interesting as an ornamental object, and if it does not continue to furnish flowers so long, it is more interesting when it is in flower, and when not so, it is one of the class never in *déshabille*.—J. BOESON.

THE "SETTING" OF GRAPES.

THERE was a period, almost within the recollection of middle-aged men, before Californian or Australian gold was discovered, or cheap glass had become the order of the day, when Vines were generally grown in houses glazed with diminutive panes of glass, nearly one-half of the roof being formed of overlaps and the other of timber; and when also, apparently to increase the quantity under limited accommodation, the young wood was trained-in as closely together as that of the Morello Cherry generally is now. The consequence was indifferently ripened wood; and when the flowering season came round the rods showed abundance of long lanky semi-tendrils, with a few flowers here and there about their extremities. This state of matters required an amount of skill to "set" the Grapes which was not always forthcoming.

The scene has now changed. Large, light, airy structures

are the order of the day; the improvement in the Vines grown in them being nearly as great as that in the structures themselves. But notwithstanding all these advantageous circumstances, indifferently "set" Grapes are by no means uncommon. How best to "set" Grapes is hence a subject which, neither infrequently nor unprofitably, occupies the pages of horticultural periodicals, particularly at the season of the year when the flowering period again comes round. Like many other processes connected with the practice of horticulture, there is much diversity of opinion amongst cultivators as to how this "setting" can best be done.

All other conditions being favourable, it is essential, in order to maintain and keep up to the highest possible point the health of the Vine (particularly while it is forming its young wood, which includes the period of its flowering), to grow it in a moderately moist atmosphere, more or less water being applied in proportion to the amount of artificial heat used, or the strength of the sunshine. The fact that this is generally understood and generally practised, has something to do with Grapes not "setting" satisfactorily—the more so, when the weather is dull and cloudy while the flowering period lasts; because the Vine, like most other exotic fruits, "sets" its flowers most surely in a warm, somewhat dry atmosphere—not necessarily dry, however, the whole twenty-four hours, but only for a few hours during the warmest part of the day, the period when impregnation takes place. In bright sunny weather this dryness is obtained, and at the proper time, by the necessary ventilation required to regulate the temperature, which allows the moist atmosphere to pass gradually out, and to be replaced by a more congenial, drier, and warmer air. When dull sunless weather occurs at this period, special attention should be given to keep the pipes sufficiently hot to allow of a temperature of from 80° to 85° being kept up for a few hours each day, the ventilators being at the same time opened sufficiently to allow of a slow change of atmosphere, so as to carry out the extra moisture with which it may be surcharged.

Grape-growers vary their treatment considerably at this stage of growth. Some prefer a very dry atmosphere and very high temperature, which doubtless is favourable for the "setting" process in, at least, some varieties, such as Muscats, Black Morocco, &c., but is unfavourable to the health of the Vine at this critical period of its growth, while actively engaged developing its tender shoots and delicate foliage, causing the growths to "come weak," and favouring the rapid increase of injurious insect enemies, which are almost sure to make their appearance at a later period in large numbers—a standing source of annoyance and injury during the remainder of the season. Others prefer a moist atmosphere, and even recommend continuing syringing during the flowering process, if the weather proves fine and plenty of sunshine occurs, so as to admit of the atmosphere inside the houses getting dried for a few hours every day. This may be safe practice if the conditions are as just explained; but if otherwise, it is unsafe, for unless the pollen is quite dry, it will not readily act, and consequently impregnation will be none at all but impossible.

The confined state in which Vines under glass are grown is not favourable to the process of impregnation—the glass excluding them to a large extent from the action of the wind, which would otherwise largely aid in spreading the pollen, and bringing it in contact with the stigma. I have long had in use here an admirable but very simple form of trellis attached only to the top and bottom of the vineries and Peach-houses, &c., with the horizontal wires screwed tight, to which the Vines, Peaches, &c., are trained. A sharp blow with the hand makes it vibrate like a fidle string, sending up from and surrounding each bunch with clouds of pollen. This is certainly a much better plan than touching the bunches with the hand, as is generally done, saving much time, and, moreover, doing the work more effectually.

As is well known to all engaged in the culture of the Vine, there are some varieties which "set" under ordinary treatment in the greatest abundance, such as the different varieties of Hamburgh, Trebbiano, Black Prince, &c. There are not a few others which will not "set" freely, unless grown in a high temperature, and assisted in the process of impregnation in some way—by dispersing either their own or the pollen of other varieties amongst their flowers; and when this is properly attended to, I believe there are no varieties but what can be successfully "set" in all weathers. Such at least has been my own experience, with the single exception of the Muscat Hamburgh, which when started after the beginning of February "sets" with ordinary attention as freely as most other varie-

ties, but when started a few weeks earlier appears to "set" equally well, and will swell for a time till after the thinning of the berries takes place, soon after which they begin to swell irregularly, whole shoulders having more than half their berries seedless and scarcely half the usual size, while others in large numbers do not grow much larger than Peas. I have observed the same thing to a less extent with other varieties of Muscats. Is this the result of partial but imperfect impregnation, arising from the want of sunshine or light? Certainly it is not from the want of heat, or caused by a stagnant damp atmosphere.

If it were possible, in general practice, to grow each variety of Vine in a separate house, I believe the treatment of each, in the hands of expert culturists, would be slightly different. Some, such as the Muscats, Black Morocco, &c., would require both root and branch temperatures higher. Others, such as Hamburghs, Sweetwater, &c., could be grown in comparatively cool houses. Some would succeed best in strong loams, others in lighter soils, all requiring thorough drainage, and a liberal allowance of water during the earlier stages of their growth. The variety of treatment applicable to the different varieties would be doubly important during the flowering period.

All this goes to show the difficulty of giving exact instructions as to treatment during the flowering process. In general, I would recommend all the Muscats and most of the shy-setting varieties to have the temperature increased both by night and day; the night temperature to run from 75° to 72°, being highest during the early part of the night, falling a few degrees towards morning, and rising during dull weather at least 10° for a few hours in the warmest part of the day, always accompanying the rise of temperature with additional ventilation. In bright sunny weather, the thermometer, with plenty of air on, may be safely allowed to rise from 90° to 95°; never omitting in some way the dispersion of the pollen during the hottest part of the day.

Free-setting varieties, such as the Hamburghs, set readily with an average of 6° or 8° less heat than the Muscats, but all Vines should have an additional heat, both by night and day, while in flower.—A. FOWLER, *Castle Kennedy* (in *Florist*).

GARDENING IN THE WEST.—No. 5.

WESTONBIRT.

WESTONBIRT is a scantily-peopled parish on the borders of Gloucestershire and Wiltshire, and so difficult of access by rail that it can scarcely be a matter of surprise that no notice, so far as we are aware, has hitherto appeared of the magnificent mansion, not yet completed, and the ample and well-appointed gardens of R. S. Holford, Esq., who is the lord of the soil here and for miles around. It may be useful to mention that the nearest Great Western station is Tetbury Road, fully ten miles distant, but travellers from the north may take the Midland line to Nailsworth, which, by a cross-country road, is a little nearer. In the latter case they will be rewarded by some beautiful views near Nailsworth, which lies nestled between two hills, with the river at the bottom, and for the last five miles they will pass half a dozen houses, and at midday in midsummer meet half that number of people. But Westonbirt, however reached, is a place well worth seeing. Everyone about town knows what a splendid mansion Mr. Holford has in Dorchester House, Park Lane, and that which he is now completing at Westonbirt, and of which on the next page there is a view*, is on an equally grand scale. No regard has been paid to cost; everything is of the most solid character and of the best workmanship. The rooms are of noble proportions and very lofty, of a dignity corresponding to that of the mansion, which it should have previously been stated is of Bath stone, and the whole is rendered fire-proof by turning arches over every ceiling—a matter of great importance in a country house situated as this is far from water. Indeed, the absence of anything like a river or lake within view of the house is a matter of regret, and the more so, as much of the surrounding land was formerly farm ground, and consequently those ancestral trees which no money can purchase do not exist; hence there is a certain flatness in the park, though time and judicious planting would remedy this. Forming a portion of the mansion is a spacious conservatory, which will cover an area of more than 2000 square feet, but which is only in course of erection, and this is connected with the dwelling-rooms by a long glazed corridor, planted with Camellias on

the back wall and climbers on the roof, and at present chiefly filled with fine-foliaged plants.

To the south-east of the mansion, in front of a terrace wall with stone pillars and brick recesses, and having handsome pavilions at each end, is the flower garden, of which the plan of one sunk panel is given on the opposite page, the other half, of course, corresponding. All the beds are surrounded by a broad stone edging, and when their summer occupants are in full bloom make a very effective display. The planting this year is as follows:—

- | | |
|---|--|
| 1. Vase, surrounded with Le Grand Geranium. | 10. Glowworm Geranium. |
| 2. Manglesii Geranium. | 11. Lord Derby Geranium. |
| 3. Purple Unique Pelargonium. | 12. Lord Palmerston Geranium. |
| 4. Manglesii Geranium. | 13. White Ivy-leaf Geranium. |
| 5. Manglesii Geranium intermixed with <i>Verbena venosa</i> . | 14. <i>Viola cornuta</i> and Cloth of Gold Geranium. |
| 6. Scarlet Tropaeolum. | 15. Yellow <i>Euothena</i> . |
| 7. Yellow <i>Calceolarias</i> . | 16. Blue <i>Lobelia</i> and <i>Gazania</i> . |
| 8. Mrs. Holford <i>Verbena</i> . | 17. Blue <i>Lobelia</i> . |
| 9. Trentham Rose Geranium. | 18. Scarlet Ivy-leaf Geranium. |
| | 19. Dwarf Blue <i>Ageratum</i> . |

The other half is planted to correspond, although the varieties used are in some cases different, and the long beds with rounded ends have an elaborate chain pattern along the centre, then come *Calceolarias*, pink Geraniums, blue *Lobelias*, and *Cerastium tomentosum*.

There is, besides, on the south side, a second terrace with

another flower garden surrounding a handsome fountain facing the centre of the upper terrace; and a Rose-covered walk with a rockery on each side leads westward. We now again approach the mansion, in front of which on this, the south, side is a smooth-shaven lawn with single specimens of trees and shrubs dotted here and there in the foreground, clumps of these at a greater distance, and farther off some old Elms. A specimen of the Japanese *Acer polymorphum* was particularly effective by its crimson foliage, though of course only of shrub-like size; we also noticed here and on the west side good specimens of *Araucaria imbricata*, *Picea Pinsapo*, *Abies Nordmanniana*, and a large *Wellingtonia*. Some rockwork, executed by Mr. Pulham, of Broxbourne, next claims attention. We have before had occasion to notice in connection with Battersea Park how well he executes this sort of work, which it must be confessed is one of the most difficult things to manage well in landscape gardening. Where rocks naturally exist the utilisation of them for ornamental purposes can generally be effected with ease and without much expense—where nature does much art is the less required—but the artificial arrangement of rocks in places where they do not naturally occur is more frequently bungled than anything we know. The biggest mountain that man can make is but a molehill to the great upheavals of nature, nor would it be desirable, even if we could attain it, to form any approach to a natural hill in

WESTONBIRT.

our gardens; but, on the other hand, more modest efforts are apt to result in miniature caves that no one can go into, masses of stones that a man and a barrow could take away in a few hours, and for which there is no *raison d'être* in a cultivated place. Mr. Pulham in this instance has made the rockwork so that it might be supposed to be the remains of the quarry from which the stones had been taken to build the house, and an excellent resemblance to a disused quarry the place bears. "Made to puzzle the geologists of a future age," Mr. Lucas, Mr. Holford's gardener, suggested; but geologists are a hard-headed as well as hard-handed race, and are not so easily taken in. The rockwork has not been long completed, and accordingly it has yet a raw and unclothed appearance, but it has a natural look, and when its newness shall have been mellowed by the hand of time, it will no doubt form a pleasing feature.

The extent of glass at Westonbirt is very large; one compartment of the garden being reserved for the plant structures, while the Peach houses and pits are placed elsewhere. Against the south-aspect wall of this compartment are an *Azalea* house, 40 feet by 15, and four vineries, together amounting to 150 feet run, in which were excellent crops of Black Hamburg, Mus-

cat of Alexandria, and other standard kinds. A portion of the outside border is covered with glass, and can be usefully employed for temporary purposes. In front of the vineries are nine ranges of span-roofed houses running north and south, varying from 15 to 21 feet wide, which are exclusively devoted to plant-growing, and more effectively arranged houses we have never entered. The specimens were not large, but they were well grown, clean, and in robust health, and we must repeat their arrangement deserved the highest commendation. The whole of these houses are heated by one of Cumming & Edmonds's tubular boilers, to which is attached 7000 feet of pipe, but there is a spare boiler which is worked month about with the other, and Mr. Lucas informs us that the temperature of the water in the flow pipe in the coldest night does not exceed 145°, so that he avoids that parching atmosphere and those troublesome insect attacks which an insufficient amount of piping and a highly-heated radiating surface are sure to entail. By means of sixty-seven valves the heat is so thoroughly under command that the coolest house can be rendered the hottest, or the reverse, as circumstances may require. Added to this the glass, woodwork, and other fittings are of the best and most enduring character, and there

is a thorough command of ventilation, in most cases by sashes moved by a ratchet and cog. The central and largest house in this block of nine is a Camellia house, 21 feet wide and 100 feet long, with a domed centre, underneath which the walk branches right and left, but followed in a straight line leads to the flower garden. Being thus an artery of communication it is more ornamental in its construction than the houses on each side of it, and has ornamental plate-glass doors, deluding the eye by reflections of its contents. The first house from the east side is filled in one division with Begonias, Ferns, Crotons, Caladiums, and other fine-foliaged plants, and the second division is an Orchid house, in which *Cattleyas* predominate. The next range, also in two divisions, is an East Indian Orchid and Brazilian house, with ample

provision for heating, and containing a tank capable of holding five thousand gallons of water. In this is an excellent collection of fine *Vandas*, of which *Batemanni* was in flower, *Calanthe*, *Saccolabium*, &c., together with beautiful plants of *Adiantum farleyense* and some other Ferns and fine-foliaged plants. In the second division was a choice collection of *Dendrobiums* and *Oncidiums*, with many other genera. The next range is a propagating house, also used as a refuge and hospital; and the fourth a stove, admirably set out with *Crotons*, Ferns, *Dracanas*, and miscellaneous fine-foliaged plants. This contains a two-thousand-gallons tank. At right angles to the last two and the Camellia house, which forms the centre of the block of glass, is a long fernery with another large tank containing many hundreds of gallons, with *Passifloras*, *Clero-*

PLAN OF FLOWER GARDEN AT WESTONBERT.

dendrons, *Stephanotis*, and other climbers on the roof, and further on *Thyrsacanthus rutilans* and *Poinsettias* make it aglow with brilliant colours. Another cross house, to the left, is at present filled with *Fuchsias*, *Coleus*, and the like, and in winter is kept gay with *Hyacinths* and other bulbs. The remaining four houses are respectively used for double *Geraniums* for cut flowers; for specimen *Azaleas*; for *Epaerises*, *Tree Carnations*, and *Primulas*; and for *Poinsettias*, which are plunged in the bed, but at present for fine-foliaged *Begonias*.

It is really a relief to have thus got over even this brief sketch of the contents of a block of houses so extensive that to have entered into details respecting them would have occupied a

great amount of space, and tired the reader, for Mr. Lucas does not leave things half done. His houses are amply, nay profusely furnished; his plants, though not remarkable for size, are evidently such that he could make them so if he desired, and then they are in multitudes. But he had not done with us, for he next introduced us into a *Palm* house, 50 feet long by 20 wide, in which were a lot of *Livistonas*, large tree Ferns, and a vast number of *Gloxinias* dried off; then into a north-aspect house where there were something like a thousand *Amaryllises*, a class of flowers which he makes a speciality, growing them most successfully, and having raised, in addition, many fine varieties.

Passing over an iron house, empty at the time of our visit, and some ranges of pits, a cool Orchid house, and a bulb house, the early forcing houses were the last to claim attention. In two of these pot Vines are grown with great success, and in one we noticed a lot of that brilliant decorative plant for rooms—especially when seen by artificial light—*Poinsettia pulcherrima*. Of these large numbers are grown, but the finest are the old plants cut back rather closely, which attain a height of 6 feet, producing bracts large in proportion. The soil which Mr. Lucas uses is peat, leaf mould, and loam, and he furnishes in addition occasional supplies of manure water.

The kitchen garden is not on a scale commensurate with the plant-growing department, for what are technically called "rough vegetables" are not in great demand. It amounts to about four acres, and including the forcing garden its extent must be considerably more. To Strawberries, Currants, Gooseberries, and Raspberries, four extensive quarters are devoted; all the ordinary vegetables are also grown, and for the extent of ground they occupied were yielding well. Here, again, we have more glass—a range of Peach houses, in three divisions, 130 feet long. Here the trees are fruited on spurs instead of on the succession-shoot system, and very successfully. They are remarkable for their size and vigour, and Royal George Peach and Elruge Nectarine were bearing 140 fruit of high quality on a tree. In the late house there was a splendid crop of Royal George and Grosse Mignonne Peaches, and Violette Hâtive Nectarine. At the back of this range are an Apple room and a Pear room, each 50 feet long, and a seed room as well, all of which can be heated when desired, and in front two long ranges of hot-water pits for Melons, Cucumbers, vegetable forcing, and Violet forcing, which last flower is in great demand and extensively grown. The Pear trees on the walls, horizontally trained, are in excellent condition; one tree of Gansel's Bergamot on a south-west wall, as well furnished with branches at bottom as at top, covered a length of 45 feet. Plums were a failure on east walls, but there was a capital crop of Green Gages on the south aspect, and of other kinds on the west aspects.

Altogether Westonbirt is a remarkable place, and most worthy of a visit by those who wish to see plant-growing well and extensively carried out, who wish to see substantially erected and compactly-arranged structures adapted for all sorts of purposes, and who wish to see a flower garden such as few mansions can boast of, it having cost, we believe, something like £10,000. To Mr. Lucas in a great measure belongs the credit of having devised and carried out the erection of the world of glass which is here found, and the arrangements connected therewith; and in him the visitor will find an able, willing, and instructive guide.

NOTES AND GLEANINGS.

THE POTATO DISEASE has broken out with great virulence in some parts of Sussex. In the parish of Heathfield whole patches were destroyed three weeks ago, and now it has become more general. It cannot be said in this instance that electricity and electric storms have contributed towards the development of the disease, as there have been no severe thunderstorms in the district this season.

— MR. D. ROBERTS, gardener, Aigburth Hall, Liverpool, writes—From a standard Peach tree, planted in the front border of Peach house here, I gathered on the 15th inst. a dish of eight ROYAL GEORGE PEACHES of the following weights: two weighed 9½ ozs., two 9 ozs., and four 8½ ozs., making the total of 71 ozs., or very nearly the average of 9 ozs. each. I considered them very fine for Royal George, and thought the weight of them would interest those who advocate the orchard-house cultivation of the Peach.

— ON the subject of DISINFECTANTS, which at this season is a matter requiring some attention, Dr. Domett Stone, physician to the Westminster General Dispensary, writes:—Most chemists give the preference to chlorine, which may be evolved by mixing in a bottle two tablespoonfuls of common salt, two teaspoonfuls of red lead, and half a wineglassful of strong oil of vitriol, in a quart of water. The bottle should be kept cool, tightly stopped, and in a dark place; a little of this fluid exposed in a saucer, sprinkled on the floor, or soaked in sheets of old linen and hung about the rooms, rapidly deodorises and destroys effluvia. An article bearing the name of "chlorozone," and professing to be a fluid of greater potency both as a deodoriser and as a disinfectant than any other at present in general use, has been brought before the public. In

writing on this agent in the "Half-yearly Abstract of the Medical Sciences," vol. 52, I have stated that it is essentially a permanganate so combined with chlorine, or chlorinated alkali, that nascent oxygen and chlorine are simultaneously available. The fluid is already in use in several hospitals, and in no case has any fault been found with its effects. It is claimed for this invention that it is the cheapest disinfectant in the market. At a time when cholera is likely to make its appearance in this country, it cannot, I think, be too forcibly impressed that the neglect of preventing disease frequently costs far more than the means themselves.

— We are requested to state that the "SOCIÉTÉ D'HORTICULTURE DES ARRONDISSEMENTS DE MELUN ET FONTAINEBLEAU" will hold their twenty-third General Horticultural Exhibition on the 13th, 14th, and 15th September, at Brie Comte-Robert. Roses will be a special feature of the Exhibition, in order to bring out their really perpetual or "remontant" habits. The show, we believe, will be of an extensive character.

WORK FOR THE WEEK.

KITCHEN GARDEN.

AFTER the first shower of rain earth-up Brussels Sprouts, Savoys, Broccoli, and whatever requires it. Keep the ground free from weeds. Remove the crops that are done with, and prepare it for winter crops. Any Broccoli that are now planted out should have their roots dipped in soot, earth, and water, and immediately after planting should be again watered. The Cape and Grange's intended for use in the autumn should also be watered. The principal sowing of Cabbage for spring use should now be made, if not already done. A few of the Horn Carrot may be sown to stand the winter, but another sowing should also be made towards the end of August. Abundance of water should be given to the *Celery* newly planted, also to the earliest crop, which, if wanted early, should be earthed-up. Continue to plant out, observing to take up the plants with as much soil about their roots as possible. Make a sowing of Cos and Cabbage *Lettuce* for late use. A few *Onions* may now be sown to draw young for winter use, or to stand the winter for transplanting in the spring. As ground becomes vacant another sowing of *Turnips* may be made; if the weather continue dry, water the ground after the seed is sown, and cover with mats.

FRUIT GARDEN.

As soon as the fruit begins to change colour keep a sharp look-out for snails and woodlice. To keep the first in check where they are numerous, syringe repeatedly with clear lime water, not doing it too late, otherwise a thin pellicle of chalk would be formed, and spoil the look of the fruit. Lettuce leaves, &c., may be strewed about the walls after being greased on one side, and examined every morning. The syringing will also decompose the woodlice, as they do not like wet, and cut stalks of beans may be inserted between the branches of the trees as traps; but the great remedy is to keep the walls in good order, so as to give no place for concealment. The very hot days are just the delight of the red spider, and if he once establishes his colonies on the under side of the leaves of Peach trees, he will rest secure for a time amid all the hatterings from your garden engine. Put plenty of sulphur in the engine, previously made into a paste, so that it may mix equally with the water; or, what is better, dab the open spaces of your wall with it, and then the more intense the heat the stronger the fumes of the sulphur will be. Vines, Peaches, and other fruit trees on walls should be divested of their lateral shoots, and those that are left for bearing next year should be neatly milled-in.

FLOWER GARDEN.

Decayed blooms should be removed from Roses, for if allowed to hang they have an unsightly appearance, and tend to encourage mildew. Roses, if in masses or beds, should be so arranged that their colours may be as much contrasted as possible. Where this has not been hitherto attended to, the present arrangement should be carefully examined while the plants are in flower, and any alterations noted that may be considered necessary to render the effect more satisfactory next season. This will greatly facilitate the task of making alterations at the proper season. Proceed with the propagation of favourite sorts, either by means of budding or cuttings. Many prefer having Hybrid Perpetuals, Teas, Chinas, and Bourbons on their own roots. Short-jointed cuttings taken off now, therefore, will root freely if properly made and attended to under a hand-glass, provided the situation is somewhat warm and shaded. The readiest way of propagating them, however, is by means of cuttings taken off plants grown under glass for flowering in spring. In some neighbourhoods black fly is becoming troublesome on Dahlias and Asters. Where such is the case tobacco water and soapsuds may be used with advantage. The strength of the mixture should be tested by dipping some of the shoots worst affected into it, and

using it sufficiently strong to kill the insects, but not so much so as to injure the leaves. It should be applied in the evening when there is a prospect of a bright night, using a fine syringe or fine-rosed watering-pot, and giving enough to moisten the whole of the foliage. Where the stock is growing vigorously pegging and training will involve considerable attention, and it will be necessary to inspect the beds frequently, removing decayed flowers and cutting-back such of the shoots as may incline to encroach upon the edging of the beds. Keep herbaceous plants neatly tied-up, and cut off the flower stems of any that are becoming unsightly. Keep the gravel walks smooth by weeding, sweeping, and rolling.

GREENHOUSE AND CONSERVATORY.

Now when most kinds of hardwooded greenhouse plants are out of doors, painting and other repairs for the houses should be done. As has been already stated, it is now time to provide and encourage an assortment of flowers adapted for blooming late in the autumn and early in winter. Camellias if forced into wood will be tolerably forward. They should be kept out of doors in a good place on cool flags or coal ashes to prevent worms from deranging the drainage. Chrysanthemums should now or very soon receive their last shift, if possible, using chiefly good fibrous loam for the purpose with plenty of charcoal. This is the best way to keep them stiff in habit and to preserve their lower leaves. Any necessary amount of strength may be imparted to them when the flower buds are formed by good liquid manure. Successions of Brugmansias, Clerodendrons, Euphorbias, Poinsettias, &c., should receive a last shift, in order that they may produce a rich display in the conservatory. Climbers on ornamental trellises should be occasionally cut back with the view of having a succession late in the season when flowers are scarce. A batch of such plants as Thunbergias, Ipomeas, Jasmynes, Stephanotis, Passifloras, &c., should be got up ornamental trellises without delay. Clematis bicolor and C. azurea grandiflora force well early in spring, provided they are rested behind a shady wall for a month or two about this season. These latter plants, although perfectly hardy, are well adapted for the conservatory trellis.

STOVE.

About the beginning of August some of the best gardeners treat their established stove plants somewhat like those of the greenhouse for five or six weeks. They either remove the plants to more open houses, or throw their stoves open on purpose, removing dwarf, tender, and young delicate plants into close frames. Whatever conveniences of this sort may be at hand should be made the most of at this time. Nothing can be more injurious to stove plants than keeping them growing late in the season, and thus preventing the ripening of their wood, which renders them more liable to injury in winter, and prevents their flowering freely next season.

PITS AND FRAMES.

The lights should now be drawn off at night where the plants are of the hardier kinds. Stout cuttings of *Plumbago capensis* struck now will force next spring for the conservatory, and may be afterwards planted out in beds in the flower garden, for which they are admirably suited. Propagate largely from those half-hardy plants which cannot be quickly struck in the spring, or that cannot be had of sufficient size to turn into the borders at that time. Sow Mizanotte and a few showy annuals for decorating the plant houses during the autumn and winter.—W. KEANE.

DOINGS OF THE LAST WEEK.

SINCE writing last week we have had some very hot days; on two or three occasions the maximum temperature in the shade rising to 90°. This on our hot gravelly soil has been very trying to vegetation, but it has demonstrated to us the high value of deeply working the soil in winter; especially in the case of such plants as are not considered deep-rooting. The ground for our *Hollyhocks* is trenched 2 feet deep, a good layer of rich manure is placed at the bottom of the trench, a spit and a shovelling of earth are thrown over the manure, another similar coat of manure is placed on it, and then another spit and shovelling. On this plot of ground the *Hollyhocks* have thrown-up immense spikes as thick as a man's arm, and are flowering grandly. Not a drop of water has been artificially applied to them. We also planted another lot of similar plants on ground which had not been trenched last winter although it had been trenched and heavily manured two or three winters previously, and the plants now present a miserable appearance; the largest proportion have not thrown-up any spikes, and those that have are very weak. Liberal applications of manure water would have had the desired effect, but during the press of work in summer we cannot find time to do this. The same with the bedding plants; for many weeks the beds have been quite full, and are in profuse bloom. Nor do we ever water them, always depending on our deep trenching and manuring; be it also understood

that this system of culture applies more especially to dry gravelly soils in dry districts. Our average rainfall is about 21 inches.

FRUIT AND KITCHEN GARDEN.

Here the same remark will apply as to trenching. We seldom get a crop of green Peas at this time of the year from the ground that has not been trenched. The plants show signs of distress, and the leaves turn yellow before the flowers open. In this department much time has been taken up in gathering the fruit for preserving purposes, and in looking over crops and picking-out any weeds that the hoe has missed; in such hot forwarding weather as we are now experiencing they soon run to seed.

We picked a good dish of *Strawberries* last Saturday; the variety was Frogmore Late Pine. This and Cockscumb have been our best late sorts in the present year. With such a Strawberry as Frogmore Late Pine we wonder that anybody can recommend the Elton. Of Cockscumb we had many fruit weighing 2 ozs. each, and none of them were thinned out, nor were the plants watered. We are cutting away the runners that have been rooted into small pots for planting out, and also for pot culture. We shall cut all the old plants up at once, and devote the ground to some other purpose. We read Mr. Wright's paper on the Strawberry and our experience is somewhat different from his. Vicomtesse Hérnart de Thury has been disappointing to us; it was not so early as Black Prince, but come in with Keens' Seedling. Late Prince of Wales we shall not grow again; it bears freely enough, but the fruit is of inferior quality, and only medium-sized.

The pickling Onions have just been pulled up and laid out to dry. A variety named the Two-bladed is grown for this purpose; we do not know a better sort. It is of very little use planting out any green crops during this weather, but we get the ground ready for doing so.

FRUIT AND FORCING HOUSES.

We have the *winter Cucumbers* ready for planting out, but we have not been able to do it yet. It is always best to have such work done as soon as the plants are ready, but when it is not convenient to do so the plants should be shifted into larger-sized pots before they become pot-bound. We have one house which continues to bear very freely. The only insect pests that have been a trouble to us this year have been red spider; syringing the house twice daily has kept it in check. Thrips, when once firmly established, is not easily got rid of, but persistent fumigation will ultimately overcome even this enemy. I think we fumigated one house at least six times before we thoroughly destroyed this pest.

Shading the houses becomes expensive; no material that has been yet tried lasts more than two years, so that it was dispensed with in the Pine houses this year. The plants look very well, but where fruit is ripe or ripening we place a sheet of paper lightly over it to prevent the sun from scorching it; if it do so the fruit will decay at once.

In the late vinery some of the berries on the Lady Downe's Grapes have become scalded through the house being inadvertently shut up too early one hot afternoon; it was not shut up entirely, but the lights were drawn up too closely. We have watched this Grape narrowly, and can freely say that the berries will not scald if due precaution be taken. The ventilation must not even be reduced unless the house falls to 65° or 70° in the evening. Lateral shoots had made some growth, and had to be pinched-off; even in the early houses we do not allow any laterals to grow after the Grapes are cut.

CONSERVATORY AND PLANT HOUSES.

The *Camellias* have now set their buds, and we have just repotted them. The pots are very carefully crocked, and the potting material is the most fibrous turfy loam that can be obtained, with turfy peat added to it. We did not disturb the roots very much, especially where the tender white rootlets had clustered thickly round the outsides of the balls. In cases where the roots were not in good condition the soil was picked away with a pointed stick, and the plant returned into a pot of the same size. The plants were placed in a house where they could be syringed daily, and the house shut up at 6 P.M.

Chrysanthemums have been again dipped to destroy fly, which continues to infest the points of the growing shoots; where it is not convenient to dip them they are dusted with dry snuff. The growing shoots on specimen plants have been trained down and tied to sticks; care must be taken in doing this, as the shoots are very liable to snap off at the joints, which spoils the symmetry of the plants.

FLOWER GARDEN.

The bedding plants have not required much attention, and as to the lawn, it is very brown indeed; it shows the nature of the soil; in deep clayey loam the grass would still be quite green. It will at least require no more cutting until rain come. *Hollyhocks*, which had previously been fastened to the sticks, have to be looked over every third day to prevent the spikes from being injured.—J. DOUGLAS.

TO CORRESPONDENTS.

* * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

GRAPES MILDEWEN (*Julia*).—Your Lady Downe's Grapes are attacked by the mildew; lose no time in dusting the whole of the Vines affected with flowers of sulphur before the disease spreads to the other varieties.

ROSE-BUDS DROPPING (*J. S.*).—Reine du Portugal and some others of the same class of Rose do not seem to have the power of developing their buds; the petals are too crowded, and there is not sufficient vigour to bring them to maturity, especially on standards. Occasionally by judicious treatment and thinning the buds, with favourable weather, good blooms may be obtained, but, generally speaking, it is better to change for free-flowerers and free-openers. When there are one hundred or more better sorts it is not of much use to persevere with a bad one.

NAME OF ROSE—STRIKING CUTTINGS (*J. R. Burton, Crondall*).—We think it is Louis XIV., but the specimen was too far gone to decide. It might be Le Rhone, though darker than it usually is. For treatment of Roses from cuttings, see answers pp. 50 and 51, to "ROSE" and "ARTURUS."

STATUES IN GARDENS (*Sunny*).—We have often remarked the grotesque effect produced by statues upon light-coloured statuary in the open air, such as you complain of. These effects may already be noticed on the fine marble figures of the Albert Memorial in Hyde Park. The fact is, our moist climate is unfavourable to the erection of light-coloured statuary in grounds, and we always think that an imitation of bronze would be much more suitable than either white or stone colour.

MOVING PLANTS (*J. F.*).—*Hedysarum gyrans* is a native of Bengal near the Ganges, and is called there Buram Chadali, or Burram Chandali. This is a wonderful plant, Linnaeus observes, on account of its voluntary motion, which is not occasioned by any touch, irritation, or movement in the air, as in Mimosa, Oxalis, and Dionna; nor is it so evanescent as in Amorpha. No sooner had the plants raised from seed acquired their ternate leaves, than they began to be in motion this way and that; this movement did not cease during the whole course of their vegetation, nor were they observant of any time, order, or direction; one leaflet frequently revolved, whilst the other on the same petiole was quiescent; sometimes a few leaflets only were in motion, then almost all of them would be in movement at once; the whole plant was very seldom agitated, and that only during the first year. It continued to move in the stove during the second year of its growth, and was not at rest even in winter. (Suppl. Linn.) Swartz observes that the motion is irregular, and that it sometimes ceases entirely; that in a very hot day it is immovable, being agitated only in the evening, and that slowly. In our climate, the leaves, in general, only make a faint and feeble attempt towards the middle of the day at exerting their extraordinary faculty. This motion does not depend upon any external cause that we can trace, and we are not able to excite it by any art that we possess. It is not the action of the sun's rays, for this plant is fond of shade, and the leaves revolve well on rainy days, and during the night: exposed to too much wind or sun, it is quiet. Perhaps, says Linnaeus, there may be some part in vegetables, as in animals, where the cause of motion resides.

UNHEALTHY VINES (*E. R.*).—The Black Hamburgh and Buckland Sweet-water Grape Vines that were planted two years ago in an outside border of a lathhouse, producing a crop of fruit the first year, but failing since then to make much growth, or to produce any fruit, are evidently in their present lamentable condition through mismanagement. By taking a crop of fruit the first year you have so weakened the constitution of the Vines that considerable time and great care will be required to bring them into the healthy condition in which you first of all received them from the nursery. Whoever advised you to take up the Vines and pot them, as a curative, knows nothing of Vine-culture. If the soil of the border is, as we suspect, of a rich, close, adhesive texture, replace it immediately with turf sods chopped roughly into large pieces, or with any sweet loam soil of an open texture, lifting the roots clean out of the soil, and shading the Vines with matting or by whitewashing the glass, syringing the stem and branches plentifully with water during the operation, and as often afterwards as appears necessary. The foliage may drop for a few days, but it will soon recover. Spread each root out to its full length in the fresh soil, pruning off all decayed parts. See that they do not want water—pure water, not liquid manure. Avoid deep planting; 6 inches of soil over the roots is ample. Do not be discouraged if no great advance is perceptible this season; the most pressing and immediate want is a healthy root-action; secure this and all will be well. In autumn, when the leaves are fallen, cut the Vines back to the bottom of the rafter, and every shoot that appears next year should be encouraged to ramble as far as possible. Avoid all stopping or pinching of the growth. If the shoots grow to the top of the house and down the back wall, becoming a perfect thicket, as is very likely, so much the better. If all has gone well, in the autumn of 1874 you will have a fine sturdy lot of canes to select from. Prune all away but the permanent cane, and shorten it in proportion to its strength; then in the following years you may reasonably expect a regular supply of fruit. Do not, however, be tempted to overcrop; only let the condition and general appearance of the Vines be your guide, and you can hardly fail to obtain the success which we wish you.

CARROTS DESTROYED BY WIREWORM (*Edm.*).—As the Carrots are probably worthless, take them up now, destroying every wireworm that is found upon the Carrots and in the soil. As winter approaches throw up the soil on the ridges, and during a severe frost again stir and turn it up deeply, so as to expose as much of it as is possible to the action of the frost, which will destroy the wireworm.

TURF GROWING OVER THE ROOTS OF SHRUBS (*E. R.*).—It is advisable to keep a circle about 3 feet in diameter around the stems of newly-planted shrubs unfurrowed for two years after planting, to facilitate watering, but after that time the turf may be continued close up to the stems.

ARRANGEMENT OF A SPRING GARDEN (*C. D.*).—The general arrangement is very good. The only beds we object to are 1, 1, in which there are too many colours to be effective in such small beds. Discard the Crocus and Ivy, filling the centre with Clematis montana, and replacing the Ivy with a broad edging of Viola cornuta. For an edging of green-foliaged Ivy to be effective, the beds should be on gravel.

GROWING CUCUMBERS IN A HOUSE HEATED BY A FLUE (*W. B.*).—We fancy that your proposed plan will answer. We would place a double layer of bricks over that part of the flue underneath the beds, otherwise there will be danger of too much bottom heat. The evaporating troughs will be necessary over the flues, and you will require to maintain a night temperature of from 60° to 65°.

VINE LEAF DISEASED (*H.*).—The affection on the back of the leaf is probably caused by a current of air in the house. We have frequently seen it in our own houses to a limited extent. It is not, as far as we are aware, injurious. It is quite different from the warty excrescences formed on the under sides of the leaves from the atmosphere being over-moist.

ROSE-LEAVES EATEN-OUT AT THE EDGES (*R. L. T.*).—Yours is a beautifully perfect example of the operations of the Leaf-cutter Bee (*Apis or Megachile centurionaris*), which we figured and thus described in the first volume of our new series:—"Every cultivator of the Rose must have noticed semi-circular cuts (*g*), made in the edge of its leaves with as much accuracy as if done by a mathematical instrument. These segmental are the work of the Leaf-cutter Bee (*h*), and made by its mandibles. The process which one of these bees employs in cutting the pieces of leaf that compose her nest is worthy of attention. Nothing can be more expeditious. With her strong mandibles she cuts without intermission in a curved line so as to

Megachile centurionaris.

detach a triangular portion. When this hangs by the last fibre, let its weight should carry her to the ground, she balances her little wings for flight, and the very moment it parts from the leaf flies off with it in triumph; the detached portion remaining bent between her legs in a direction perpendicular to her body. This bee lives alone, belonging to the group of solitaries. The body is about half an inch long. The female, which is the leaf-cutter, is black, covered with ash-colored hairs; jaws or mandibles large, terminating in four teeth; antennae black, rather longer than the head; wings slightly transparent, dark tipped, veins black; legs hair, spurs dull red, pollen-bristles of hind legs golden; abdomen heart-shaped. The male's body thickly covered with yellow hair; antennae longer than head; jaws two-toothed; dense yellow beard between the antennae; fore tibiae dirty yellow at the outward tip; abdomen rather oval, extremity indented, absolutely toothless.

CUCUMBERS DISEASED (*W. D.*).—The leaf you sent us shows that the plants have had but little air, and are not vigorous. Give them more air, maintaining a temperature of 65° to 70° at night and 75° by day, and 85° to 90° with sun and abundance of air. Slight shade from bright sun is beneficial, but excepting during the last few days has not been needed. In other respects we think your treatment right, only still loam is not so good for Cucumbers as that of a medium texture inclining to be light rather than heavy. The shoots should be trained 16 inches from the glass, and in no case touching it. The leaves show evidence of the disease.

MELONS DISEASED (A. S.).—The leaves you have sent us are damaged by some insect, not woodlice nor wireworms, though the latter may have done mischief to the roots, which alone would be sufficient to account for the plants growing so badly. The only remedy would be to replace the plants and soil with fresh. Eighteen inches is a great depth for soil; we never have more than a foot. We regret not being able to help you to a remedy that would preserve the plants. If at all like the leaves sent, the plants are beyond cure.

GAMB INFESTING ASPARAGUS (G. P.).—We think your Asparagus is attacked by the larvae of the Asparagus beetle (*Circulifer asparagi*), which feeds up on the leaves, perforates the ribs, and destroys the pint of the stem. Peeking off the larvae is the only means we know of freeing the plants of this insect. The beetle may be shaken off into a sheet.

POTATO PIT LIGHTS (A. Constant Subscriber).—We recommend 21-oz. sheet glass, third quality. Your frame or pit being wide ought to have sashes 2½ inches deep, and 1½ inch thick, styles 2½ by 3 inches, and top and bottom rail to correspond. Do not have the lights wide; we find wide lights very cumbersome, and liable to get out of order. 3 feet to 3 feet 3 inches will be sufficiently wide for the pit. Have the sash bars stayed by flat bar-iron stays 1½ inch by three-eighths, two to each light; they all to the strength and durability of the lights.

ORCHARD-HOUSE FRUIT TREES CASTING LEAVES AND FRUIT (Wm. A.).—The most likely cause, and, in fact, we think the sole cause, of the trees casting their leaves and fruit is the removal of 2 inches of the surface soil, taking away with it breaking, or disturbing a great many of the roots, and those the most important, then filling up with rich compost. No more than the bare surface soil should have been removed, and that without interfering with the roots.

CUCUMBERS SHRIVELLING AT THE POINTS (H. M.).—It is caused by a check to the growth that may be occasioned by too heavy waterings, employing cold water, and keeping the atmosphere too close, moist, and cold. Probably a little more air, and not keeping the plants so moist, would set them all right.

SOIL FOR GERANIUMS (A. C.).—Your soil requires two-thirds more loam, and about a fourth of the whole of well-rotted manure.

WATERING MELONS WHEN RIPENING (P. C., Herts.).—It is not desirable to water Melons when ripening, but enough water should be given, as there are others swelling, to keep the foliage fresh, as on that depends the perfecting of the fruit. It ought to be given without wetting the surface much, pouring it between the Vines. A three-gallon watering-potful to each light will be sufficient if applied twice a week in bright weather, and once a week in dull periods. It ought to be a rule never to let water come on the stem or collar of the plants, and not only that, but it ought not to be rowled or shaded by leaves. The foliage drying up, it is likely, though the Melons will ripen, that they will be small, and in case of the foliage dying off water should be withheld.

UTILISING BACK WALL OF VINERY (A. Learner).—The back wall will not answer for Peaches after the second year, and we should not advise you to employ it for any kind of fruit trees, as the Vines will shake the wall as to render it quite unsuitable for their successful cultivation. The only plants we have found suitable are Camellias and Oranges. Either will suit. The former are the more valuable. As you do not propose to have any fire heat in the coming winter, you may plant the Vines in autumn.

ACACIA SEEDS (J. K.).—Sow them in the ordinary way and keep the soil moist. Boiling water would destroy the vegetative power.

PEACHES FOR ORCHARD HOUSE (T. W. C. M., York.).—The Peaches will all succeed in an orchard house, and they will ripen in succession. Noblesse being the earliest; but neither of them is an early variety. The Nectarines will also ripen in an unheated orchard house. If you would like one of each earlier than those you name, you may have Early Beatrice Peach and Violette Hative Nectarine.

DRIED FLOWERS (Ferd. Lutz.).—If you allow the flowers to get too ripe they will shed their seeds; but if you harvest them in good time and hang them in a dry shady place they will not do so.

MADERIA VINE (Ledy C.).—We do not know, and can find no trace of such a plant. Kindly send a specimen. You will find the culture of *Dentzia gracilis* detailed in No. 632, pages 372 and 373. Antierhinna cuttings may easily be struck in autumn and spring if treated like *Verbena*; and excellent plants, which will flower the same year, may be raised from seed sown in March.

WHEAT BLIGHTED (E. A. H. C.).—The Wheat is attacked by a fungus; *Puccinia graminis*, which is a form of the Barberry blight, *Erysium berberidis*. They are the same parasitic fungus in different stages of development. Although it was long supposed to be a popular error that the Barberry and the Wheat blight had any connection, a Danish professor, (Ersted), established the fact.

NAMES OF PLANTS (J. W.).—Your Begonia is a florist's variety, and we cannot name it. (*B. var.*—*spira*) *Pilipendula flore-plena*. (*A. W.*)—*Lactuca Frit-mas cristata*. (*B. var.*)—1, *Pteris arguta*; 2, *Alois-a inae-silifolia*, a native of Peru. (*S. Ippam.*)—*Salsibarua a laudifolia*. It can be obtained from any good nursery. (*B. var.*)—*Veratrum nigrum* (*W. D. H.*).—It is a *Cynoglossum*, but the specimen is not enough to determine what species. (*H. W. Bury.*)—*Nephrolepis exaltata*. (*C. L.*) *Dactyloctenium*.—*Mimulus cardinalis*. The Milk plant is another species of the *Lychnis* genus. (*J. D.*)—1, *Polystichum angulare Kitsonii*; 2, *Athyrium Filix-foemina*; 3, *Lactuca Frit-mas cristata*; 4, *Scopolendrium vulgare crispum*; 5, *Scopolendrium variabile*; 6, *Polystichum angulare intermedium*.

Wright attributes the success obtained in a great degree to the system being entirely carried out without exception.

"The greatest practical difficulty in keeping any non-sitting breed of poultry, like Leghorns, is that of obtaining a sufficient number of hens from other sources to hatch and rear the broods, which in a large stock is sometimes a serious obstacle. From the introduction of two such valuable races of non-sitting poultry as Houdans and Leghorns during late years, the need of a really practical incubator is more felt than ever; but even in the absence of this, much can be done to remedy the inconvenience by bringing up the chickens artificially, or without the hen, leaving her to hatch a second brood, and then dismissing her. We have already given Mr. Halsted's views in favour of this practice, coupled with somewhat of a doubt as to this mode of rearing being, however, quite equal to the care of a hen, much less superior to it. We had, however, never applied the system ourselves to the whole chickens of a season, which we have since learnt is essential to a really fair trial, since under a partial attempt the chickens with the artificial mother are tempted away to the hens with other broods, and thus get fretted. We were, however, exceedingly interested to see, in May, 1873, the working of the artificial system as thoroughly and entirely carried out by Mrs. Frank Cheshire, of Acton, Middlesex, so well known for her fine stock of Light Brahmas. We saw there upwards of seventy chickens, all brought up under an 'artificial mother,' as one brood. They ranged in age from three months to three days, but there was no fighting, or tyranny of the strong over the weak; not one had died (more than we could say of our own), and there was not one sickly or discontented chick in the whole lot; while we were most of all interested to observe that the birds were larger for their age than our own; and that the trouble was nil compared to that of a dozen hens with their broods, to which we went back with a most discontented mind.

"The 'mother' was about 4 feet 6 inches long by 16 inches wide; the top, or heating portion, consisting of a flat tank about 1 inch deep, with the top soldered on, and having only one inlet for pouring in water, or immersing the bulb of a thermometer to ascertain the temperature. This tank extends all over the mother, and is kept in position by a wooden frame, which supports it at about 6 inches high at the front, and some 3½ inches behind. Under the lower or back edge, occupying some 2 inches of the under side, a flue extends the whole length of the tank, which is provided with two chimneys, one at the end or corner near the lamp, the other at the further extremity of the flue. This is necessary for such a long horizontal flue: for without the first chimney the carbonic acid would flow back and put out the lamp when first lighted, though it will freely travel to the further chimney when the flue is warm; moreover, if the night be warm the first chimney alone may be left in operation, but if cold, the heated air is compelled to pass along the whole length of the flue. The tank has a partition soldered in it, round which the water circulates, and by this means the temperature hardly varies in any part. The lamp is merely introduced under the end of the flue. Any good lamp will do, but Mrs. Cheshire's was the most simple and yet most perfect in its action which could possibly be. A piece of small brass pipe was put through a loosely-fitted cork (loosely fitted to give air) in a common glass bottle partly filled with benzine. This bottle is laid on its side on the ground, and a wick being passed through the pipe, the nearly horizontal position of this simple wick-holder enables capillary attraction to draw sufficient fluid through such a length of pipe (18 inches if required), that the most explosive liquids can be used without the slightest danger; moreover, such a wick trims itself, as if drawn too far out the surplus is at once burnt off, and a small and nearly smokeless flame produced without any trouble whatever. This lamp is better trimmed twice in twenty four hours, but will burn tolerably for even the whole of that time without attention.

"Under the tank fits a frame which slides in and out, on the top of which canvas is stretched, to which are sewn the ends of strips of flannel or felt carpet—about 2½ inches long by half an inch wide—which give warmth to the chickens. Mrs. Cheshire informs us that she finds this better than sheepskin, never entangling and strangling the chicks. Under the whole slides a wooden floor, covered pretty thickly with dry mould, which is renewed every day. In the morning the mother would have a little unwholesome smell from the bodies of so many chickens; but our ingenious informant had found an effectual way to remove this, which was easily done by turning the canvas part of the mother upside down, throwing a few shovelfuls of dry earth among the flannel strips, shaking the earth well in, and after letting it remain a few minutes shaking all out again, the little earth that remained adherent coming off on the chickens, and thus benefiting them in another way. This, and the lamp in cold weather, was all the care required, beyond that of the newly-hatched chicks, which was rather a pleasure than otherwise. A rail fence in front of the mother prevented the chickens using it after reaching a certain size, but they were still allowed access to one unwarmed.

POULTRY, BEE, AND PIGEON CHRONICLE.

REARING CHICKENS ARTIFICIALLY.

Few people have had much success in superseding Nature's plan for rearing chickens; but it will be remembered that some time since Mrs. Frank Cheshire stated in this Journal that all her Light Brahmas of this year were so reared. In the ensuing part for August of Mr. Wright's "Illustrated Book of Poultry," there is an interesting account of Mrs. Cheshire's apparatus and method of treatment, which we copy. It will be seen that Mr.

"The few difficulties found at starting had been easily overcome. The two essentials were: first, that the chicks were immediately taken from the hen, so as never to miss and fret after her; and, secondly, that for about two days they needed keeping in a box floored with dry earth, with a small mother at one end, so that they could not wander away from it. This was "the preparatory school for young gentlemen," its sole object being to teach them to know the apparatus and how to go under it. As soon as they were perfect in this lesson they were turned down with the others, the whole being treated as one large brood, and agreeing perfectly. Mrs. Cheshire's small mother consisted of an ordinary indiarubber foot-bottle filled with boiling water, and placed over canvas about 10 inches square, stretched on a frame, and furnished with flannel strips as in the case of the larger one. This occupied half of a common wooden box, the chickens having the other half to run out n. If a few thicknesses of flannel are placed over the bottle, it will keep it warm enough for a whole night; and even when boiling will not be too hot for the chicks, the indiarubber and mother under being bad conductors of heat. Should such a separate infant nursery be thought troublesome, Mrs. Cheshire suggests that a small portion of the large mother may be penned-off and furnished with a small enclosed run in front, so that the chicks cannot wander away till they have learned to know it, which is the sole object desired.

"Both plans of rearing having been fairly tried by the lady from whom we have obtained these interesting particulars, the comparative results are stated by her as follows:—"The advantages of the artificial plan seem to be—1. Great economy of hens if they are needed for laying. If a hen be kept cooped with chicks for three weeks [and we should say five weeks is nearer the mark], she has been six weeks out of the breeding-pen; and after she is returned to it her first four or five eggs will not be fertile. 2. Economy in food; as all eggs, grits, and other dainty food go to the chicks. Special dainties for very young ones are easily given in a feeding-coop, through which the larger ones cannot pass. 3. Economy in labour of feeding and cleaning. This is very great, while there is always capital dry accommodation for the chicks on wet days. 4. The extreme tameness of the chicks. A hen often prevents her brood feeding till the attendant has gone; but under this system little chirpers of three or four days old will run and flutter up to whoever has the charge of them; and they never seem to fight or quarrel. 5. The impossibility of losing chickens by tramping. 6. The greatly increased cleanliness of the chickens, which retain the utmost purity of their beautiful down until its loss. Our experience also proves that they feather more quickly. And, lastly, increased size; we find that we get the same weights on this plan at ten weeks old which we formerly got at twelve weeks. I might add the possibility of raising fine chicks early in the year; since if cold weather comes on they can nestle even at eight or ten weeks old if they will."

"We ought to add that we are thoroughly convinced by actual inspection of the great superiority in every way of this plan of rearing, and that Mr. Halsted's enthusiastic praise of it was fully borne out. The principal reason of the success is, in our opinion, that every chick can have as much brooding as it likes, whereas, when with the hen, weakly ones may often be seen and heard entreating warmth and shelter which the vigorous ones do not need, and which the hen will not give. These chicks die off, while with the artificial mother they are nourished into strong birds. The only difficulty is to tell the different strains, which to the fancier is important. Mrs. Cheshire effected this by dyeing them on the back. By the time this disappears the memory can often be trusted; and if not they can then be marked in other ways.

"The subject is so important to many, that we have thought it well to give this further information upon it while treating of the last of the more useful non-sitting breeds of poultry."

CASTLE EDEN DISTRICT POULTRY SHOW.

(From a Correspondent.)

The sixteenth annual Show of the Castle Eden Horticultural Society was held at Seaham Hall, near Sunderland, on the 22nd inst. *Spur-tish* were a good class. Of *Dorkings* there were few, but the first and second prizes went to good large birds. The first and second *Cochins* were first-class pens. *Brahms* were of fair merit. Of *Hamburghs* there was a good number in the four classes, although several pens did not arrive until nearly noon, and of course too late to be judged. In *Game* there were several birds of superior merit. Two very good pens of *Bantams* were shown, but it was thought by some of the fancy that the commended pen should have been placed second. The class for *Malays* excited considerable interest, as many of the fancy had subscribed for a cup, and most of the supporters of this breed sent their best birds. The first pen consisted of a very beautiful cock bird and a good Partridge-coloured hen, the latter of a colour which is more required in Malay classes. The second-prize pen from the same exhibitor was moulting, but to

my fancy I should have given a preference to the second-prize cock, as being of the true type of Malays. I never saw a better tail, and he was long in the legs and neck. The third-prize birds were the largest in the Show, but the cock lacked condition, and was of a very dark colour; the neck had too many feathers on—a fault with all the rest of the birds. This pen, to my fancy, should have been fourth. The fourth-prize cock bird was of fair merit, but deficient in the true style of a Malay, especially in the length of the leg and neck. The hen was too much of the common colour. The Rev. N. J. Ridley sent a pen, of which the cock was the best coloured bird in the class, and the hen of fair merit. The cock certainly seemed shorter in the legs than the other prize birds, which was no doubt his only fault.

- SPANISH.—1 and 2, R. Moore, East Rainton. 2, A. Buglass, Durham.
- DORKINGS.—1, Mrs. Bardon, Castle Eden. 2, A. Buglass.
- COCHIN-CHINA.—1 and 2, G. H. Procter, Durham. c, J. Lawson, Sunderland.
- BRABMA POOTRA.—1 and 2, R. Moore. c, W. Whitfield, Hutton.

- SELLING CLASS.—1, H. Yardley. 2, C. Norman, Westfield.

- RABBITS.—*Lop-eared*—1, F. Banks, London. 2, W. Canner, Leicester. *hc*, Hon. P. Hastings, Derby; M. M. Cashmore. *Any other variety*—1, E. S. Smith, Boston. 2, J. T. Hinks. *hc*, F. Banks; S. C. Pignat, Huckleby; F. Sabbage, Northampton (2); E. S. Smith.

JUDGE.—Mr. E. Hewitt, Sparkbrook, near Birmingham.

LISKEARD POULTRY SHOW.

(From a Correspondent.)

The fifth annual show of poultry was held at Liskeard on the 21st inst. The entries were more numerous than in any former year, there being upwards of 180 pens of poultry and Pigeons, divided into twenty-nine classes, competing for prizes varying in amount from five guineas to three shillings. *Game* headed the list, and were most numerous, and the class for single cocks of any White-legged variety, for the improvement of table poultry, brought out as fine a lot of Heggies as were ever exhibited, together with some Muffs and Tassels. There could scarcely be

a doubt as to those birds being of the pure old type of Game fowl, as some of the best birds were disqualified for being trimmed or cut for the pit. In the class for Reds, Brown Reds took first and second honours, the first being a gamey-looking pen in good feather. The second went to a pen of large size, with a body old co-cockers would describe as being "as long as a ship," and with a coarse long head—in fact, one of the true exhibition breed. Third came a good-coloured pen of Black Reds, a little stilty in leg. Pen 12 with a bad hen contained the best cock in the class, and of the perfect symmetry and cone-like shape we were wont to see at the first Birmingham Shows. The first-prize pen of Duckwings deserved second and third also, as there was nothing besides in the class worth looking at, and with the exception of the cock being faulty in the feet, this was the best pen of Game shown. *Dorkings* were good, especially the White Rose-combs, and the second-prize pen of Coloured should be cheap at the price (£2 2s.), they were entered at. *Spanish* were moderate, and *Minorcas* were one of the best classes in the Show. *Malays* or *Indian Game* made a very fair class, and the first-prize pen was awarded the piece of plate for the best pen of *Malays*, *Cochins*, *Brahmas*, or *French*, and well deserved it. *Cochins* were moderately good, the best pen being disqualified for making and trimming tails, and although they had passed muster at other recent shows, the experienced eye of the Judge detected the manipulation. *Brahmas*, with the exception of the winning pens, were scarcely up to the average quality. The same may be said of the *French*, and nothing of any especial merit could be found in *Polish* or *Hamburgs*. *Game Bantams* were out of condition; a small stylish pen of Black Reds were first, Brown Reds second. In the class for *Bantams* of any other variety, first came fair Golden Sebrights; second, Black Rose-combs. The winners in the Variety class were White Sul-tans and Black Hamburgs. In the *Selling Class* Partridge *Cochins* were first, and a pen of *Spanish* that would have been first in the *Spanish* class if shown there, were second.

Pigeons, although not numerous, were represented by some good birds, and the *Pouters* were the best both as to quality and numbers ever shown at Liskeard. The Variety class contained some excellent birds, Frillbacks being first, Runts second, and *Jacobins* third.

Mr. Clogg, the Hon. Sec., was most assiduous in his attention to the birds, in the care of which he was assisted by an experienced Committee. The awards were made by the Rev. G. F. Hodson.

SWEETSTAKES FOR SINGLE GAME COCKS.—*Henniss, Tassels, Muffs, or any other White-legged Game, adapted for table purposes.*—1, Miss B. Short, Liskeard. 2, H. Jones, Avonwick. 3, J. Jones, Looe.

GAME.—*Black-headed or other Reds.*—1, W. Craig, Duloe. 2, J. T. Browne, St. Austell. 3, Coon Bros, St. Austell. *Any other variety.*—1, J. T. Browne (Blackwing). 2, and 3, Mrs. B. Short.

DORKINGS.—*Coloured.*—1, F. F. Fowler, Lismore. 2, C. H. White, Liskeard. *Any other variety.*—1, J. H. Nicholls. 2, F. Rundle, Lostwithiel.

SPANISH.—1, J. Bassett, Lostwithiel. 2, H. Feast, Swansea.

MINORCAS OR ANCONAS.—1, R. Box, Bodmin. 2, T. P. Burton, St. Austell.

MALAY OR INDIAN GAME.—Cup and 1, W. H. Huxtable, Barnstaple. 2, Rev. W. Hickman, Warminster.

COCHINS.—1, J. H. Nicholls. 2, H. Feast.

BRAHMAS.—1 and 2, H. Waterman, Devonport. 3, J. H. Nicholls.

FRENCH.—1, H. Feast. 2, J. Godfrey, Liskeard. 3, W. H. Copplestone, Lostwithiel.

POLANDS.—*White-crested.*—1, Miss F. Solomon, St. Blazey. 2, G. Liss, Par Station. *Any other variety.*—1, S. Frobert, Lostwithiel. 2, Miss F. Solomon (Silver-spangled).

HAMBURGS.—*Gold or Silver-spangled.*—1, J. Clark, St. Day, Scourie. 2, H. Feast. *Golden-pencilled.*—1, G. Liss. 2, H. Feast.

BANTAMS.—*Game.*—1, F. Scamfield. 2, W. Garrah, Par Station. *Any other variety.*—1, Miss A. Clogg, Liskeard (Sebrights). 2, J. Nicholls.

ANY OTHER VARIETY.—1, S. Probert (Sultans). 2, W. W. Beckerley, Lostwithiel (Black Hamburgs).

SELLING CLASS.—1, W. W. Eckerleg (Partridge Cochins). 2, J. Bassett (Spanish).

DUCKS.—*Aylesbury or Rouen.*—1, Mrs. S. R. Harris, Cugarne, St. Day (Aylesbury). 2, C. H. White (Rouen).

PIGEONS.

CARRIERS.—1, G. Packham, Exeter. 2, H. Yardley, Birmingham.

POTTERS.—1, H. Yardley. 2, H. Holloway, Stroud.

TUMBLERS.—1, H. Yardley. 2, J. Broad, Plymouth.

FANTAILS.—1, G. Packham. 2, J. Crook, Exeter.

DRAGONS.—1, H. Yardley. 2, G. Packham.

ANY OTHER VARIETY.—1, H. Denham, Exeter (Frillbacks). 2, J. Crook (Runts). 3, A. Darnell, Exeter (Jacobins).

BLACKBURN POULTRY SHOW.

This was held on the 21th inst. The following awards were made by Mr. R. Trebay, the poultry Judge:—

DORKINGS.—1, J. White. 2, J. Robinson. *hc.* T. Hornsby; W. Harvey.

BRAHMAS.—1, T. F. Ansell. 2, H. Beldon. *hc.* F. Wadlington; T. F. Ansell.

SPANISH.—1, L. Leeming. 2, Furness & Suddell. *hc.* H. Beldon.

GAME.—1 and 2, C. W. Brierley. *Cock.*—1 and 2, C. W. Brierley.

COCHINS.—1, T. Aspin and Nuten. 2, W. Harvey.

HAMBURGS.—*Golden-pencilled.*—1, J. Robinson. 2, H. Beldon. *hc.* J. E. Wenses. *Silver-pencilled.*—1, H. Beldon. 2, J. Robinson. *hc.* J. Bowness. *Golden-spangled.*—1, H. Beldon. 2, J. Robinson. *hc.* G. & J. Duckworth; J. Bowness. *Silver-spangled.*—1 and 2, J. Robinson. *hc.* H. Beldon. *Black.*—1, H. Beldon. 2, J. Robinson.

BANTAMS.—1, H. B. Smith. 2, H. Beldon. *hc.* J. Warts; E. Walton; T. Waddington; T. Copper. *Game.*—1, L. R. Robinson. 2, and *hc.* W. F. Entwice. *Cock.*—1, W. F. Entwice. 2, W. F. Adhe. *hc.* J. R. Robinson.

POLANDS.—1, H. Beldon. 2, T. Waddington. *hc.* W. Harvey.

HOLLANDS.—1 and 2, G. W. Hibbert.

SELLING CLASS.—1, J. Bowness. 2, Furness & Suddell.

GRSE.—1 and 2, J. Walker. *hc.* L. Anson; S. H. Stott; J. Houker.

DUCKS.—1 and 2, J. Walker. *hc.* J. Higham; T. Tomlinson. *Rouen.*—1 and 2, T. Wakefield. *hc.* J. Walker. *S. H. Stott.* *Any other variety.*—1 and *hc.* H. E. Smith. 2, C. W. Brierley.

TURKEYS.—1, F. E. Rawson. 2, J. Walker. *hc.* W. Section.

RABBITS.—*Long-eared.*—1 and 2, J. Boyle. *Angora.*—1, G. C. Hutton. 2, J. W. Harling. *Humblyton.*—1 and 2, S. Ball. *Silver-Grey.*—1, S. Ball. 2, J. Boyle, jun. *Any other variety.*—1, J. Boyle, jun. 2, J. Irving. *hc.* S. G. Hudson.

HITCHIN POULTRY SHOW.

The following is the list of awards made at the Show held at Hitchin on the 24th inst., at which Mr. Martin and Mr. W. B. Tegetmeier were the Judges respectively for poultry and Pigeons.

DORKINGS.—*White.*—1, J. Robinson. 2, O. F. Crosswell. *Coloured.*—1 and Cup, J. C. Bunnell. 2, Rev. E. Bartrum. *hc.* Rev. E. Bartrum (2); J. Robinson; F. Barlett.

COCHINS.—*Ruff.*—1 and Cup, Lady Gwydyr. 2, T. F. Ansell. *hc.* J. K. Fowler. *White.*—1, J. K. Fowler. 2, K. S. S. Woodgate. *hc.* R. S. S. Woodgate; J. J. Malden.

BRAHMAS.—*Dark.*—1 and Cup, T. F. Ansell. 2, H. Lingwood. *hc.* R. Fulton. *Light.*—1, M. Leno. 2, H. Feast.

FRENCH.—1 and Cup, J. Robinson. 2, R. B. Wood. *hc.* R. B. Wood; W. Dine (2); H. Feast; E. Lutton; J. J. Mahlen (2); J. K. Fowler; G. R. Hibbert.

SPANISH.—1 and Cup, Nicholls Bros. 2, J. F. Sillitoe.

GAME.—*Reds.*—1, J. Jekin. 2, S. Matthew. *hc.* E. M. L. Cocksedge; R. Swift. *Any other colour.*—1 and Cup, S. Matthew. 2, H. E. Martin.

HAMBURGS.—*Spangled.*—1, Cup, and 2, J. Robinson. *hc.* H. Feast; J. B. Bly. *Frilled.*—1 and 2, J. Robinson. *hc.* T. Edmunds.

POLISH.—2, G. W. Boothby.

ANY OTHER VARIETY.—1, Lady Gwydyr (Silky). Extra 1, J. Robinson (Black Hamburg). 2, J. K. Fowler. *hc.* Rev. N. J. Bidley.

SELLING CLASSES.—(3s.).—1, T. F. Ansell. 2, Lady Gwydyr (Cochins). (£1 1s.).—1, L. Wren (Brahmas). 2, Cross & Mansfield (Dorking).

LOCAL CLASS.—1, S. Tuke (White Cochins). 2, S. Lucas (Light Brahmas). *hc.* A. Ransom.

BANTAMS.—*Game.*—1 and *hc.* R. Newitt. 2, G. Garrod. *Any other variety.*—1 and Cup, M. Leno, Dunstable. 2, C. Reed. *hc.* M. Leno; W. H. Tomlinson, Newark.

NEWCASTLES.—1, J. K. Fowler, Aylesbury. 2, M. Leno. *hc.* Rev. R. L. Story; W. Drog, Faversham; J. Robinson, Garstang; E. Lounour; J. J. Malden, Biggleswade.

PULLETS.—1, M. Leno. 2, Rev. R. L. Story. *hc.* A. Darby, Bridgenorth; W. Drog; J. K. Fowler; J. Robinson; A. Hanson (2); E. Lantur (2); J. J. Malden. *hc.* G. H. Fitz-Herbert.

DUCKS.—*Aylesbury.*—1, Cup, and 2, J. K. Fowler. *hc.* G. Kirby; J. Robinson. *Rouen.*—1 and *hc.* J. K. Fowler. 2, J. H. Barnes. *c.* J. H. Barnes; Rev. E. Bartrum. *Any other variety.*—1 and 2, M. Leno (Vidua and Aumannal). *hc.* Capt. C. F. Terry (2); J. J. Malden.

GRSE.—1, J. K. Fowler. 2, J. H. Barnes.

PIGEONS.

POTTERS.—*Cocks.*—1 and 2, R. Fulton, London. *hc.* R. Ashton; W. Nottage.

HENS.—1 and 2, R. Fulton. *hc.* R. Ashton.

CARRIERS.—*Cocks.*—1 and *hc.* R. Fulton. 2, H. Yardley. *c.* R. Blacklock.

HENS.—1, Cup, and 2, R. Fulton. *hc.* T. Chambers, jun.

BARBS.—1 and 2, R. Fulton. *hc.* H. Yardley. *c.* C. Norman.

TUMBLERS.—1 and 2, R. Fulton. *hc.* H. Yardley. *c.* G. Lucas.

OWLS.—1, R. Fulton. 2, H. Yardley.

TRUMPETS.—1, O. E. Crosswell. 2, H. Yardley.

JACOBS.—1 and 2, R. Fulton. *c.* W. Larkins.

FANTAILS.—1, J. F. Loversidge. 2, O. E. Crosswell. *hc.* R. Fulton; W. H. Tomlinson.

ANY OTHER VARIETY.—1, W. Larkins (Yellow Dragons). 2, L. J. Price (Loughon Hunt). *hc.* H. Yardley.

SELLING CLASS.—1, W. Nottage (Barbs). 2, J. Ford (Carriers). *c.* W. Larkins.

RABBITS.—*Long-eared.*—1 and 2, F. Banks. *Silver-Grey.*—2, G. Beckley. *Any other breed.*—1 and 2, F. S. Schage. *hc.* F. Banks. *Selling Class.*—1, F. Banks. 2, E. Day. *hc.* Rev. — Loughborough. *c.* G. Beckley.

WESTWARD HO POULTRY SHOW.

We have often thought that Falstaff would have had more bread to his sack had one been as accessible as the other, or had facility been afforded to him. The tapster was deaf to the cry for bread, but alive to the cry for another pottle. This, added to the inclination for the liquid, caused the undue consumption of one as compared to the other. It is a great thing to have at hand all that you are likely to want. Acting on this principle, our good and kind western friends had on one day poultry, Pigeons, and horses; on the other day poultry, dogs, and donkeys. The great magician of the north, so long known as the "Author of Waverley," made the fortunes of the inhabitants of the places he described by attracting people to see them, and so our magician of North Haunts has created a place by his vivid description of Hildford, the Tor, and the surrounding country, the abode of the admirable Mrs. Leigh, of Frank, of Amyas, good Sir John Brimblecombe, sterling Will Cary, gallant Grenville. As we walked the streets we thought to meet "The Rose of Torridge," and we looked about for something to connect us with the time of "good Queen Bess" and the deeds of the giants of those days. We did not look far. The first name we saw on a shop front was "Heard." We thought of Michael "of that ilk" striking down the noble Spanish captain, and sinking with him and his ship. As it is said you should always leave off with a success, we sought no farther in the town, but sought the new creation, "Westward Ho," a mighty pleasant spot in summer and autumn, but we should think somewhat dreary in winter. It is struggling through its present, but it must have a future. There is a gradual rise from the unique pebble beach, two and a half miles in length, to the top of lofty wood-clothed hills, and the embryo town stands midway. The unkind storms and the ground swells have twice

carried away the pier, but, nothing daunted, another is built, and was opened on Thursday last.

The show ground was well chosen—a level space, with the woods and the sea below. On it stood a large tent containing poultry and Pigeons, a very large one to cover a hundred and forty horses; the Channel Islands cattle stood without cover. A capital grand stand was erected, facing an enclosed space, where for three hours the spectators were indulged with "high jump," "double jump," "water jump," to the great delight of the numberless ladies who crowded the stand. Then a large lifeboat came out from somewhere or other fully manned, the crew in red caps, and encased in cork jackets, seeking every opportunity of taking her into bad water or rough surface, but it was useless. She was in every respect above it; she hardly seemed to float on the waves, but to skim over and touch them, as we sometimes see swallows. The access to the show yard was only prevented by a hedge in some parts and hurdles in others. We fancied these latter would prove an insufficient barrier, but our friends are wise, and just before the time for admission drew nigh they were thickly smeared with liquid tar. This answered the purpose.

The number of entries of poultry was affected by a similar show—i.e., poultry and dogs, being held at Liskeard, and another being advertised at Exeter within a few days. We publish a list of the prizetakers. The best classes were *Dorkings*, *Game*, *Cochins*, *Brahmas*, and *Bantams*. It is a matter of regret that everywhere the *Spanish*, the *Hamburghs*, and the *Polands* show so badly. It must sooner or later bring about a change in the prize sheets. The *French* breeds, at least the *Crève-Cœur*s and the *Houdans*, challenge notice, and deserve it. Light *Brahmas* should have a class. The *French* breeds we have named are excellent layers. If it be the characteristic of any birds to lay in the winter, these may claim the property. The *Ducks* would have shown better, but some good specimens were put in the wrong classes. The *Geese* were very heavy, and the *Whites* unusually good. The *Turkeys* were good, and showed, as they do almost everywhere, that the American is spreading all over the country.

The *Pigeon* show was an excellent one, bringing many first-class birds. There were large numbers of people on the first day, but the weather was very unfavourable on the second.

- DORKINGS**.—1, J. Heal, Parkham. 2, H. Feast, Swansea.
SPANISH.—2, H. Feast.
GAME.—*Black-breast or other Reds*.—1, J. Boyle, Barnstaple. 2, N. H. Parker, Tawstock, Barnstaple.
COCHIN-CHINA.—1, Mrs. Christie, Tapeley, Instow. 2, H. Feast.
BRAHMAS.—1, Miss B. How, Woodville, Biddeford. 2, H. Feast.
HAMBURGH.—*Gold-pencilled*.—1, H. Feast. *Gold-spangled*.—1, H. Feast. *Silver-spangled*.—1, H. Feast. *Silver-pencilled*.—1, H. Feast.
POLANDS.—1, Mrs. Viall, Langtree. 2, H. Feast.
SELLING CLASS.—*Cock*.—1, J. W. Tacott, Barnstaple. *Hen*.—1, Mrs. Christie, Tapeley, Instow. 2, J. A. Lyne, Newport, Mordenouth.
BANTAMS.—*Game*.—1, Miss E. How, Woodville, Biddeford. 2, J. Heal. *Any other variety*.—1, F. Braund, Biddeford. 2, S. Synnolds, Barnstaple. *hc*, A. M. Pigott, Braunford Speke, Exeter; W. Willis, Liskeard.

 Mr. Bailly was the Judge.

GAINSBOROUGH POULTRY SHOW.

For many years the heat of the weather has not been so great as it was at the time of the Gainsborough Show. The sole motive of allusion to this fact is, that it leads to a subject of vital interest to the owners of first-class exhibition birds. It appears that two valuable specimens, an American Turkey cock and a fowl of great size, the latter exhibited by the owner under the name of "Pookain," were both found dead when received at Gainsborough. It should be remembered by exhibitors that though travelling baskets closely covered with thick canvas are suitable for the conveyance of poultry in winter, or even in ordinary weather, yet during times of great heat, and the day oppressively sultry, if such baskets are (as usual) packed closely in a horse-box on the railway, it is not uncommon to find plenty thoroughly exhausted on their arrival, and some dead. It is but just to remark, had it not been for the careful and prompt attention of those having the management of the poultry tent, several other pens of poultry would have been utterly ruined as

show fowls, for they arrived so thoroughly prostrate as to be unable to stand even for a moment. Baskets cannot be too airy under such circumstances.

The Show itself was limited as regards numbers, but the majority of the poultry were very superior specimens. The *Game* fowl were unquestionably very fine, the major portion being in really good plumage. The *Golden Polands* and *La Fleche* fowls were capitally shown, as was also one of the best pairs of perfectly white *Guinea fowls* ever exhibited. *Dorkings* were very large well-grown specimens, but dropping fast into moult. *Cochins* were not equal in quality to those of former years, and the same remark applies with equal force to the *Hamburghs* and *Game Bantams*. Good Silver-laced *Sebrights* and *Black Bantams* were respectively the winners in the division appointed for them. The *Turkeys*, *Geese*, and *Rouen Ducklings* were of a very superior character. The *Dark Brahmas* were also very fair, but the Light-feathered ones were exceedingly poor. A small but really good collection of *Pigeons* appeared to be very popular with visitors.

The arrangements in the Show tent for the poultry were well managed; in fact, it was generally remarked that the poultry tent was the coolest and most comfortable spot in the whole exhibition field. The attendance was satisfactory, and the Judges were Mr. Tegetmeier, of London, and Mr. Hewitt, of Birmingham.

EXTRA.—1, E. G. Fane, Grantham.

GAINSBOROUGH CAGE BIRD AND RABBIT SHOW.

As the Lincolnshire Agricultural Society's Show was this year held at Gainsborough, and prizes were offered for poultry and Pigeons, the Gainsborough Society waived their claim in favour of the Agricultural Society, and held only a floral fete, gala, and bird and Rabbit Show, at which the prizes were but small and the classes somewhat limited. The consequence was that in the Rabbit section the entries were not numerous, though some of the classes of *Cage Birds* were well represented.

First in the section to which we refer was a class for *Yellow Canaries*, the first prize for which was borne off by a nice Norwich, the second being also taken by that variety; in *Bufs* the Norwich fancy was likewise to the front. In *Green* or *Variegated* the first was a *Jonque Norwich*, which was the best of these three sections; the second prize going to a *Yellow-marked* bird, and an extra prize was awarded to a very handsome *Cinnamon* nestling, which through some mistake was placed in the wrong class. An almost perfect *Golden* bird stood first in the *Lizard* class—in fact such a bird as is rarely seen; and the second-prize bird was a *Buff*, also of fair quality. The *Goldfinches* and *Linnets*, as is usually the case in this part of the country, were well shown, in nice plumage, and very tame, and the *Parrots* and *Parraquets* also in good feather. In the *Variety* class a pair of *Love Birds* stood first, with a *Thrush* of this year second; and a *Brambling* or *Mountain Finch* was highly commended.

In *Lop-eared Rabbits* only the winners were noticeable. In *bucks* the first prize went to a *Black-and-white* 21½ inches by 1½ in ear, and the second to a light *Tortoiseshell* 21½ inches by 1½. The does were, first a splendid *Tortoiseshell* 21½ inches by 1½, and second a *Fawn* 21½ inches by 1½. The *Himalayans* were all good specimens, and the heaviest *Rabbit* weighed 14½ lbs., the second being 13 lbs. 12 ozs. in weight.

On the first day of the Show the visitors were not so numerous as we could have desired, but we hope to hear better reports of the second day.

CAGE BIRDS.

- CANARIES**.—*Yellow*.—1, G. Eason, Gainsborough. 2, F. R. Gilling, Worksop. *hc*, T. Green, Gainsborough; F. M. Barton, Gainsborough. *Buff*.—1, W. Dill, Gainsborough. 2, T. Green. *hc*, G. Kayner; A. Burdett, Gainsborough. *c*, F. M. Barton. *Green or Variegated*.—1, W. Hill. 2, T. Green. *hc*, G. Kayner; T.

Green; R. Wykes; Gainsborough; F. M. Burton; J. Forrest, Gainsborough. *Gold or Silver Spangled Lizard*.—1 and *hc*, W. Hill. 2, G. Rayner. *GOUDINCH*.—1, G. Rayner. 2, W. Temperton, Burnham, Bawtry. *LINNETS*.—1, T. Kirk, Burnham, Bawtry. 2, W. Temperton. *AC*, T. Green; J. Lynnes, F. Worth. *PARROT*.—1, T. King, Gainsborough. 2, A. Kirk, Gainsborough. *hc*, W. Anderson, Gainsborough.

PALM-PIGEON.—1, J. Bloom, Gainsborough. 2, J. Tait, Gainsborough. *ANY OTHER VARIETY*.—1, J. King (Love Birds). 2, J. Landin, Gainsborough (Thrush). *AC*, Mrs. Forrest, Gainsborough (French Chat).

RABBITS.—*Lop-eared*.—*Buck*.—1 and 2, Shaw & Allison, Sheffield. *hc*, J. Hannam, Gainsborough. *Doe*.—1 and 2, Shaw & Allison. *Himalayan*.—*Buck or Doe*.—1, S. Ball, Bradford. 2, S. J. Hudson, Hull. *AC*, S. Ball, Bradford; G. Aylesby, East Retford; F. Ledger, East Retford. *Beanoet Buck or Doe*.—1, Miss F. Booth, Gainsborough. 2, W. Anderson, Gainsborough. *Extra*.—*hc*, D. S. Mackay.

BRAMLEY POULTRY, PIGEON, AND RABBIT SHOW.

The schedule of prizes offered was a slight improvement upon that of last year, and the increase of entries fully answered the expectations of the Society. The specimens were placed under a light and airy tent, in which ample shade from the almost tropical sun was found for large numbers of visitors. The pens used were those of Mr. Turner, of Sheffield, and the birds and Rabbits were well fed and attended to with water.

Of *Spanish*, two pens were extremely fine in quality of face and drop, but the third pen proved coarse, and the cock's face was almost red. *Cochins* were but a poor lot, and the birds in two of the pens had badly diseased feet; the winners were Buffs. *Brahmas*, which were all of the Dark variety, were very much better, and may be termed a fair lot. *Red Game* were but poor as a class, though the cock in the first-prize pen and the hen in the highly-commended pen were fine birds; the chance of the latter, however, was entirely destroyed by the cock, which, in addition to being bad in colour, was both duck-footed and unsound in feet. The second prize went to Black-breasted Reds, but in bad feather. In *Game*, any other variety, there was no entry. *Polish* were good in all particulars, and all of the Golden variety. *Hamburghs* had five classes; the entries were not numerous, but the lot was almost uniformly good. In *Red Game Bantams*, chickens in full feather won both prizes; an adult pen, which was highly commended, was also very good. In the Variety class for *Gaiole*, Piles were first and second, no others being worthy of notice. In *Black Bantams*, the first prize went to a very neat pair, although the cock's comb was rather large. The second-prize pair were neater in head, but not so small, and good in style. *White Bantams* were first in the next class, and silver *Sabrights* second. *Ducks*, Rouen or Aylesbury, were a grand class. In the Variety class, which was very attractive, *Kawarkas* stood first and *Pintail* second.

There was one class for chickens, in which some good and forward specimens of several varieties were shown, and many were noticed, *Spanish* of great promise being first, and fine *White Cochins* second. In the Variety class a capital pair of *Grey Dorkings* were first and *Guinea Fowls* second. In the Selling class the first prize went to *Light Brahmas* and the second to *Spanish*. The cup was won by Mr. Beldon with *Spanish fowls*.

Pigeons were more numerous than the poultry, and throughout the classes the birds were very good in quality, although some were to a certain extent faulty in feather; but we are sorry to say that several pens were empty on account of some delay in the transit. *Carriers* were first on the list, the first-prize bird being a capital young *Black cock*, and the second a *Dun*, good in wattle and eye, but rather crowded in head. *Pouters* were a pretty even lot; the first prize went to a *Red* and the second to a *White cock*, being large birds and in good show. *Dragoons* came next, both winners being *Blues*; the first prize went to a particularly well-shown pair. Of *English Owls* there were but two pairs really in competition, the rest being either in bad feather or half bred foreign, a fault not to be admitted now that the class is well supported with birds of the old English type. The first-prize *Turbits* were *Blues*, spike-crowned, and full of character, but foul on the thighs, the second being very good shell-crowned *Reds*, but out of feather. *Jacobins* were very good in all particulars, and the first place was taken by *Reds*, the second by *Blacks*. The winning *Trumpeters* were of the foreign variety: *Mottles* first and cup, and *Blacks* second. *Tumblers* were mostly *Red Mottles* in the Long-faced class, the winners in both cases being nearly perfect birds of that variety. In *Short-faces* both pairs were *Almonds*, good in head properties, and well broken in markings. *Fantails* were a beautiful lot, and an extra prize was offered for this variety, which was won by Mr. Loversedge with an exquisite pair. *Barbs* were good, and both prizes were won by the same exhibitor, the first with *Blacks* and the second with *Duns*. In *Long faced Antwerps* the winners were *Red Chequers*, and in *Short-faces* capital *Silver Duns* were first and *Red Chequers* second. There were some bold birds in the single *Antwerps*—birds that seemed possessed of extraordinary powers of flight,

and the prizes were given to a *Red* first and a *Blue Chequer* second. In the Variety class the first prize went to *Spangled Ice*, the second to *Nuns*, both pairs being very handsome.

The Selling class contained some very costly birds, which we doubt not would be secured at the very earliest opportunity. The first honours were taken by an *Almond cock*, and the second position by a *Black Swallow*.

Lop-eared Rabbits came next, and the measurement was tolerably good, but the heat seemed to affect some to an alarming extent, and had not it been for this the order of the winners would, in our opinion, have been reversed. The first prize was taken by *Grey-and-white*, 21 inches by 4½ in ear-measurement; and the second-prize, *Fawn-and-white*, 20 inches by 4½, was larger than the first-named. *Silver-Grey* were good in fur, and almost uniform in colour, as well as of good size, and the pretty *Himalayans* left little to be desired in point of colour and marking. The Variety class contained capital specimens of the *Angora*, which stood first; a handsome *Black-and-white* specimen of *Dutch* was second, and a *Belgian Hare Rabbit*, which in point of fur might easily have been taken by a novice for a common *Hare*.

We published the names of the Judges and prizetakers last week.

CARBOLIC ACID FOR DESTROYING PARASITES ON FOWLS.

In the Journal of July 17th, page 53, an extract from Mr. Wright's "Illustrated Poultry Book" [see page 70], recommends for chickens a few dustings with a very few drops of carbolic acid mixed with powdered brimstone when they require purifying. Let me recommend all poultry managers to let carbolic acid alone, and only use brimstone, as I have seen the effect of the former on a dog. A very little carbolic acid had been put in his bath, and the effect was most alarming. The dog could not stand after it, and not till sweet oil had been applied to him both externally and internally did he begin to recover from the sort of fit he was in. Therefore, let no one try it without knowing exactly the proportion that may be used safely.—BEWARE.

TO COLUMBIAN SOCIETIES—PROPOSED PIGEON SHOW.

In answer to the able letter in your last issue from "A." I must say a few words. The Northern Counties Columbian Society (Manchester) some weeks ago issued a challenge in your valuable columns to any Columbian Society to have a friendly meeting, giving every Columbian Society in England, Scotland, Ireland, and Wales, the chance of challenging, or accepting the challenge laid down. This challenge still remains open, and I trust some steps may soon be taken in order that two societies may meet. I have written very fully to two societies on the subject of a friendly rivalry, and therefore am not anxious now to trouble you with a long letter, but in conclusion I must say that I do not at all approve of the prize list "A." proposes, and think the first show ought to be held in the town from which the challenge emanates. The return show might be held in the acceptor's town; and as the object of a Columbian Society is to improve the breed of Pigeons, and not to promote financial speculations among exhibitors, money prizes should be entirely omitted.—PRESIDENT OF THE NORTHERN COUNTIES COLUMBIAN SOCIETY (MANCHESTER).

POINT CUPS FOR PIGEONS.

When I promised my next should be on the point cup question, I did not expect to be so long in giving my opinion.

In the first place, I would give Mr. Maynard every credit for his excellent letter of May the 15th on the subject, for he proves very feebly how wrong it is of committees to give cups to be so competed for, as they encourage the dishonourable system of borrowing, and end in (as Mr. Maynard observes) disappointing purchasers, who are led to believe that the birds at home are the same strain. This alone is sufficient to condemn the practice. I am not going to dispute the fact that generally where a point cup is given there are not more entries than there would otherwise have been; yet not always in such cases of abundance is it owing to the existence of a point cup; for money prizes, class cups and medals, and the appointment of good judges, have far more power over small exhibitors than the sight of a cup as a present to one of the largest exhibitors. When a prize list has been got up, everything considered to please small exhibitors, it is a certainty that the large ones will enter as well, and that there must be all that committees could wish for. Committees must not overlook a fact very perceptible at shows now-a-days, that fanciers are much more wide-awake than a few years ago; for the question seems now to be, "If I cannot borrow so-and-so's birds it will be of no use trying to win the cup with

my own few breeds, as the three-deck sweepers will be there and what chances have I? So I shall see what other shows, there are on the same date." Such is the question with many a would-be exhibitor. There is also a highminded kind of fancier who would scorn to possess a cup won by the aid of birds other than his own, for his conscience would never allow him to be proud of such a cup, as he would feel that it was not all his own.

However, the question is whether a point cup makes a show really a financial success, and just and satisfactory to all exhibitors? I have endeavoured to prove that it does not, and far from it, for it is discouraging to exhibiting fanciers, and disgraces the fancy at large; and if any committee dispute my statement, there need only be a voting paper sent out to all exhibitors, and the result would prove how few there are in favour of the point cups.—IMPARTIAL.

FRUIT IN TIN CANS.

THE Boston Journal of Chemistry says:—The impression prevails among those who use freely fruits which are put up in tin cans that they are injured thereby, and this impression is in many cases correct. We have long contended that all preserved fruits and vegetables should be stored in glass, and that no metal of any kind should be brought in contact with them. All fruits contain more or less of vegetable acids, and others that are highly corrosive are often formed by fermentation, and the metallic vessels are considerably acted upon. Tin cans are held together by solder, an alloy into which lead enters largely. This metal is easily corroded by vegetable acids, and poisonous salts are formed. Undoubtedly many persons are greatly injured by eating Tomatoes, Peaches, &c., which have been placed in tin cans, and we advise all our friends who contemplate putting up fruit to use only glass jars for the purpose.

OUR LETTER BOX.

POULTRY-KEEPING FOR PROFIT (Gallus).—What is your space, and how is it covered? Is it planted, or is it grass, or is it sand? Fowls are not so amenable to pre-arrangements as it is sometimes wished, and that which looks easy on paper is found impossible in practice. We advise you to start on a smaller scale. We believe in your neighbourhood there is a good sale for eggs during the summer and early autumn. You may depend on them, but if your hens are confined they will not lay as many as if they were at liberty. For that market you should keep some non-sitters—say Creve Coeurs; for your chickens, Dorkings. You must know what the consumption will be in your neighbourhood. It may be, as you say, one thousand per month, but we do not think they will bring you 6s. per couple after July. We have our raisings about artificial rearing. It is very easy to hatch, but difficult to rear, and you should, therefore, have hens to come off when you are hatching, and thus contrive to make a hen take from twenty to thirty chickens. They must have a run. Chickens cannot be reared in confinement. They must be well fed from the time of hatching, and should then be fit to kill at from fourteen to sixteen weeks. They will never fatten in such a place as you describe, with food always before them. They should be fed four times per day on soft food, and it would pay to put up a few and feed as peckers, making them rather better. Our advice on the whole is to begin on a small scale, and to try to produce your chickens earlier, as they will be worth more.

POLAND HEN SITTING (B.).—We are much obliged for the interesting fact you send to us. It was curious to hear of a Poland hen sitting, still more to find her a good mother; but having done so three years in succession, it is a second nature with her.

DARK BRAHMAS WITH DISTENDED CROPS (L. H. C.).—We keep a large number of Brahmans, and know nothing of the disease you mention. They have loose crops sometimes, but they do not die of it. We hold them up by the legs till the crops are quite empty, then shut them up, giving them but little food, and that in the smallest possible quantities. In very bad cases we give water with a preparation of alum in it. They have a very small quantity three times per day, and generally recover after a few days. We cannot think your birds have died from crop disease.

EXHIBITING DORKINGS (T. C. E.).—Whenever two birds are to be shown together they should be used together, or it is likely when in a small pen they will disagree, and disfigure each other, destroying all hope of success. Turn the bird out when he comes home, and he will soon be at home again. We do not think it would answer to operate on the crop. Let her alone. It is rather an eyesore, but the hen is not injured by it as to her utility. We know no one who undertakes a poultry post mortem. Be your own operator.

REARING YOUNG PHEASANTS (Cranford).—You will have no difficulty whatever in keeping your Pheasants. They have arrived at an age when they cease to trouble. You must enclose a place, on grass if possible, about 20 feet by 20, with hurdles made of split fir or other wood. The hurdles should be 14 feet high, and the laths forming them 1 inch apart. They should be fastened to upright poles, to which they should be attached. This is all that is necessary, as the birds require no shelter of any kind, and in such a place ten Pheasants may be kept as long as it is wished. Their food should be barley. It is necessary to cut one wing before they are put in such a pen; and as it may be desirable to turn some out, and to keep in others, you should select the best and strongest, cut their wings, and put them in. Let the others fly away as soon as they will. As a rule, they take to roosting in the hedges, they go higher and higher till they reach the trees; in the same way they become less punctual at feeding time, till they absent themselves altogether. If you keep only four birds you will require a pen only half the size of that we have mentioned. You may change their food at times by giving Indian corn or dough made of barley meal, and shaken with milk or water. They should have fresh water always by them.

MUD BATH (H. S.).—As a rule we find rain, dew, and the frequent upsetting of the water vessels generally supply all that is requisite in the way of

moisture. We are, however, always glad to learn, and will try your plan. We have sent your other question to the gentleman you name.

ARTICHOKE BOTTOMS TO KEEP (Amateur, Cirencester).—Boil your artichokes till you can pull off all the leaves, and thoroughly clear the bottom; put them into salt and water for an hour; then take them out, and lay them in a cloth to drain. When they are dry put them into large, wide mouthed glasses, with a little mace and sliced nutmeg between, and fill up with distilled vinegar; cover them with mutton fat melted, and the down with leather or bladder.

METEOROLOGICAL OBSERVATIONS, CAMDEN SQUARE, LONDON.

Lat. 51° 32' 40" N.; Long. 0° 8' 0" W.; Altitude 111 feet.

Table with columns: DATE, 9 A.M., IN THE DAY, Barometer at Sea level, Hygrometer (Dry, Wet), Direction of Wind, Temp. of Air at 5 ft., Shade Temperature (Max, Min), Radiation Temperature (In sun, On grass), Rain.

REMARKS.

- 23rd.—As bright as yesterday (the warmest day of the season), but temperature moderated by a cool breeze; frequent lightning in E.N.E. from 10 P.M.
24th.—Another brilliant day, but much cooler, the wind at times being very strong; rather storm-like in the evening.
25th.—Morning fine with pleasant breeze; afternoon fine, but with more wind; storm-like between 4 and 5 P.M.; fine night.
26th.—Dull morning, slight rain till noon; fine afternoon and evening.
27th.—Fair but cloudy morning, fine by 11 A.M.; occasional showers during the afternoon; heavy rain for short time about 6.45 P.M.; fine starting night.
28th.—Lovely morning, bright, yet cool; rather cloudy at noon; fine afternoon and evening.
29th.—Hazy early, but soon clearing off; cloudy at noon, and rather so at intervals during the day.
Air temperature very nearly the same as last week, but that of the earth much higher, owing jointly to time being required for heat to penetrate even 1 foot of soil, and to the influence of the cool breezes not having any (or, at any rate, any appreciable) effect on earth temperature.—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 30.

The supply is well kept up, and business generally is sound and good, last week's rates being fully maintained with one or two slight exceptions.

FRUIT.

Table listing various fruits and their prices: Apples, Apricots, Cherries, Chestnuts, Currants, Eggs, Filberts, Gobs, Gooseberries, Grapes, Lemons, Melons, Mulberries, Nectarines, Oranges, Peaches, Pears, Pine Apples, Plums, Raspberries, Strawberries, Walnuts.

VEGETABLES.

Table listing various vegetables and their prices: Artichokes, Asparagus, Beans, Beet, Broccoli, Cabbage, Capers, Carrots, Cauliflower, Celery, Colewort, Cucumbers, French Beans, Garlic, Herbs, Horseradish, Lettuce, Mushrooms, Mustard & Cress, Onions, Parsley, Parsnips, Peas, Potatoes, Radishes, Rhubarb, Salsify, Savoy, Scorzano, Sea-kale, Shallots, Spinach, Tomatoes, Turnips, Vegetable Marrows.

POULTRY MARKET.—JULY 30.

LONDON is fast going out of town, and the trade feels the effect of it. Prices are falling, and the demand for goods of high quality becomes daily less.

Table listing poultry prices: Large Fowls, Smaller ditto, Chickens, Goslings, Green Geese, Duckings, Pheasants, Partridges, Hares, Rabbits, Wild ditto, Pigeons.

WEEKLY CALENDAR.

13	W	OLD LAMMAS DAY.				74.5	50.0	62.3	19	44	1	25	7	44	9	6	11	20

From observations taken near London during forty-three years, the average day temperature of the week is 71.0°; and its night temperature 50.4°. The greatest heat was 95°, on the 19th, 1842; and the lowest cold 33°, on the 11th, 1831. The greatest fall of rain was 1.11 inch.

STRAWBERRY CULTURE IN A POOR SOIL.

F all garden fruits the Strawberry is most highly esteemed, and it is certainly worthy of its high position as the general favourite. Perfectly hardy, very prolific, the choicest and most highly flavoured kinds, however delicately constituted, being equally amenable to the simple method of culture that suffices for the most sturdy or robust, it might reasonably be expected that an abundance of fine fruit would be the general

result, and not so frequently the exception as it is. A variety of reasons might be adduced for such frequent failures, or rather partial successes, but it will be enough for my purpose if I take that which I think is more generally applicable than any other—namely, ignorance of the real requirements of this plant, leading to an untimely and, I fear in some instances, slovenly system of culture, if it can be fairly called a system at all. It is not at all uncommon, when looking at fine crops of Strawberries, to hear such exclamations as, "Ah! my soil will not produce such fruit as this." To this I have only to reply that Strawberries of all kinds may be cultivated perfectly well, and with little, if any, difficulty in the poorest soil, and to impress this as clearly and forcibly as I can upon many who evidently would like to succeed, I cannot do better than state something of my own experience.

The garden of which I now have the care is a new one, and a very short time ago its site formed part of an extensive wood, a remnant, probably, of that huge forest which for hundreds, perhaps thousands, of years overspread so much of the counties of Sussex and Hampshire. After clearing away the trees the soil proved to be very shallow, and of the poorest description it has ever been my lot to cultivate. Starved and exhausted by successive generations of trees, it was about as ungenial a staple for Strawberry-culture as could well be found. The portion selected for the first Strawberry bed was trenched about 18 inches deep, taking care not to bury the surface soil, but only turning it over, and chopping it to pieces; then 6 or 8 inches of rich farmyard manure was spread over it, and well worked-in with forks. The Strawberries were next planted, and well watered till they became established in their new quarters. This was done late in autumn, yet, notwithstanding, the whole of the plants survived the winter, and made a respectable growth next spring, most of them throwing-up some flower-trusses, which were promptly removed. An occasional dose of liquid manure was given during the summer, more manure forked into the soil between the rows early in August, and in the following summer of 1872 a full crop of fine fruit was taken. Meanwhile other beds were made in a similar manner, and in the present season the entire crop of fruit has been equal in size and abundance to any I have ever had or seen in those rich loamy soils which so many of us vainly sigh for.

Thus it will be seen that no very scientific appliances,

or uncommon skill were necessary to produce such desirable results, but only the ordinary care and painstaking that most other crops require. The only difference that has since been made, is to plant as early in June or July as is practicable, so as to have the plants sufficiently established to produce an early crop of fruit in the following season. Plants that have been forced in pots are in every respect to be preferred, because they yield a full crop next season. Failing such, excellent beds may be made by securing the earliest offsets from established plants, and even when plenty of forced plants can be secured, an annual bed of the young runners or offsets is very useful, as the fruit, being less shaded by the foliage than that on the older plants, ripens earlier, and thus lengthens the season. Another important point is always to destroy exhausted beds. No Strawberry plant will continue in full bearing longer than two seasons. It is true that fruit may be taken for several years from the same plants, but such fruit is invariably of a paltry description, quite unfit for the dessert.

To reduce these notes to the form of a few simple rules, it may be stated that—

1. The soil must be drained, stirred deeply, and thoroughly manured.
2. The plants, if forced pot-plants, should be planted in June, or if not, as early in July as they can be severed from the old plants, taking care that they do not suffer from want of water, either then or at any subsequent period.
3. Immediately after the fruit is gathered give a liberal dressing of rich manure, forked slightly into the surface between the rows.
4. Destroy the old beds after the second, or at most the third, year of planting.
5. Let your beds be large enough to enable you always to supply the finest-picked fruit for the table, the aim being that every dish of fruit shall be fit to compete for a prize. The small fruit is always as useful for culinary purposes as the large.

Owing to the prevalence of wet weather during the present Strawberry season some valuable experience has been gained concerning the relative value of many varieties, more particularly as regards the development of flavour and sufficient firmness of texture to withstand the hurtful effects of excessive moisture. The fruit of the early and prolific Marguerite, fine as ever, suffered so much that I should be glad to find a substitute for it; its splendid fruit was almost flavourless, and very much decayed before it was ripe. A variety that is as fine, prolific, and early as it is, with the high flavour of Keens' Seedling, and the firmness of Newton Seedling, would be a great acquisition; till such a kind is forthcoming I must keep Marguerite, for it is much too useful a variety to be lightly discarded. The huge fruit of Cockcomb suffered a good deal from rotting, notwithstanding that wire supports were used; and to my surprise, that most excellent kind Sir Charles Napier suffered very much, its large clusters of fruit being so crowded that the accumulation of moisture among the berries induced decay to a serious

extent. President has been most useful; it suffered more from the loss of flavour than from premature decay. The varieties that have proved best of all for flavour, and for resisting the attacks of damp, are Lucas, Dr. Hogg, and Frogmore Late Pine. These were all good, ripening in the order in which they are named, and yielding an abundant crop of fruit of much excellence in every respect. It would, of course, be unwise to discard any good kind simply because its fruit was spoiled by the excessive dampness of the season, but it is certainly advisable to let those sorts predominate that are found to possess such valuable properties as are fully developed in Dr. Hogg and Frogmore Late Pine.—EDWARD LUCKINIST.

BLUE FLOWERS.

A SHORT time ago Mr. Hobson communicated to the Journal an interesting letter on the white flowers of the garden, and certainly this colour, by its cool, quiet, contrasting effect, is indispensable in the setting of a floral picture. In the many examples of floral criticism—for on this question nearly everybody claims the right and power to criticize—there are a thousand verdicts every year of "too much scarlet" or "too much yellow," against one of "too much white," and the odds are nearly as great in the matter of "too much blue." No colour is more universal than blue, none more admired, and none more expressive. It is the colour that pervades the very elements of Nature and reigns there and in the petals of flowers a very queen of beauty whose loveliness can never be impeached. It is found only occasionally in the feathered tribe, and never without increasing the beauty of plumage. In the vegetable economy it is never found in the stern working department of leaf, branch, or stem. Amongst the wondrous beauties of earth we can, besides the normal green, find foliage draped in white, and brown, and yellow, and red, and even nearly black; but no blue leaf has yet been seen, or stripe or blotch, save in the flower. Above all other colours it is honoured as the emblem of constancy and truth.

It is, however, a fact that the flower gardens of the present day are singularly destitute of the ever-admired and charming blue. There are, it is true, the blue *Lobelia* and the exceedingly useful varieties of *Viola*; *Ageratum*, too, where it is used, gives a gentle touch of it, and the pure rich gloss of *Salvia patens* is occasionally admitted. But can this be all of the numerous array of blue flowers that are admitted into the garden? It is verily so, and why? The imperious fashion of "bedding-out" has driven the rest away. I will not rail against the fashion, but would prefer it to have its sting. It gives enjoyment, demands skill, and reflects credit to owner and handicraftsman. But in saying this, I say also, bring back the blues, and let them have a plot too. Use them in simple natural mixture. There will be new delights every morning, and the blue flowers will afford a refreshing change from the monotonous masses of the formally-planted beds.

I am led into this dissertation by the verdict of a garden party—a party of ladies intent on flowers and criticism. They were new-fashioned ladies in an old-fashioned garden, but the old garden was in new fashion in the matter of colour—a predominance of blue. To see these modern ladies admire the ancient flowers was a treat. They were under the thrall of blue, for it was just then *Delphinium* and *Campanula* time. What a list of blues do these two names alone afford! Still the plants are as varied in habit as their flowers in colour. Look up at the 6 to 8-foot pillars of *Delphinium*, the rich deep blue of *Hybridum Raunenilorum*, and the old *Hendersonii*, at the pale or faded blue—just now fashionable—of *Mrs. Gerard Leigh*, at the dazzling dancing azure of *Felix Poulett*, and grant at once that these things are worth growing. The colour of the last-named is "altogether lovely," and compels a pause of every passing lady. Look down from the *Delphiniums* to some of the dwarf *Campanulas*, and do not disdain them. Do not disdain the old and sterling *Carpatica* with its mass of telling colour of its own peculiar blue. To descend lower, do not disdain even the annual forms of this family; only to see them in their beauty they must be turned into biennials by autumn sowing. Without enumerating I will take the simplest and commonest of all, and venture to assert that no one can disdain it when grown as it ought to be and seen in all its richness in June and July—I mean *Venus's Looking-glass*, *Speenaria Speenham*. What! name low common things like these! Yes, however "low" it may seem to be in high gardening days, "these common things" shall have a niche because they deserve it, and because they are old

friends, with a long history behind them and a long future before them, for they can never be driven away. Their native beauty will ever preserve them from annihilation, in spite of fancy, prejudice, and fashion.

Are they transient? So is the Rose, so are all things beautiful. They are admired the more for that. Even an everlasting bloom of Roses would pall on the vision and deaden appreciation. Condemn not flowers for being transient. If we sometimes regret their departure the regret is momentary, and new hopes arise in new births and an ever-recurring succession. Is not this transient character, so much deplored, one of the greatest gifts of Heaven? It gives new life, new hope, new appetite, and the earth seems always young, and yields fruit of ever-fresh enjoyments. But blues are not transient. Employ in addition to the families named the old blue *Salvia* freely. Turn the *Veronics*, the *Myosotis*, the *Nemophila* to account. Cherish the *Viola*. Throw in the old *Trachelium* and the venerable and rich-robed *Tradescantia virginica*. Let the *Convolvulus* have a place in summer, and the little *Scillas* and *Anemones* in spring, and tell me not blue flowers are transient. They are not transient, but too sparingly used, or a host of ladies coming from gardens of their own would not exclaim in pleasure on seeing their favourite colour alive and in flowers.—J. WRIGHT.

KENT.

OUR county, on which we rather pride ourselves, has received but scant justice lately at the hands of travellers. A Mr. l'Estrange has lately published one of those books which seem to be got-up for Mudie's, in which one writes most charmingly about the decaying villages of Romney, &c., which are in effect more flourishing than they have been for some time. And now, *proh pudor!* Mr. Witherspoon, whose love for the *Gladiolus* one must honour, runs through the county and records his impressions, in which he pours great contempt on our farming, and deplores the miserable condition of our south country labourers. Travellers' tales are proverbial, and travellers' impressions are often hastily put to paper and pass current for shrewdness.

Now let me tell my tale. First as to the laud. Railways do not always run through the best land of a country. Who would judge of the north of France by the line of country from Boulogne to Paris, or in our country of the midland counties from the line from Huntingdon to Peterborough? And it so happens that the South-Eastern Railway runs for part of its course through some of the worst land of the county—hard "clity" clay: and no worse punishment could we wish to any farmer who had wronged his fellows, than to set him down to farm this land. Hungry and cold, no farming can ever make it remunerative. Mr. Witherspoon expatiates, too, on the use of the scythe on brown meadows, and the absence of the mowing machine. Ours is not a pasture but an arable county, and probably there are fewer mowing machines here, for the simple reason there would not be employment for them to repay their outlay. In my own parish there are farms where not a ton of hay is made this year, but the mowing machine is in use here where there is any breadth of laud laid down. We do not cut our grass brown, and I should not be at all surprised to find that what Mr. Witherspoon saw was men brushing meadows where sheep had been fed, but where the grass had grown "strandy," and in consequence had to be brushed over. Then as to the matter of wages. I do not know what Mr. Witherspoon calls poorly-paid labourers, but the lowest rate of wage here is 16s. 6d. to 17s. per week, independently of harvest work and hopping; and if he had kindly paid me a visit I could have taken him into cottages, and that not one or two, but many, where he would have seen neatness and comfort such as I venture to say he would not find in the houses of our much-belauded and overpetted mechanics. I am sorry he falls into the loud talk about an age of progress, &c. About the Docks, Thistles, &c., let me say there is a worse weed than any of these which we ought to do more to eradicate—the drinking habits, which from all we hear are as prevalent amongst Durham miners as Kentish labourers.

This is not, strictly speaking, horticultural matter; but, as a "man of Kent," my back was rather put up by what I cannot but consider hasty judgment and wrong opinions. There is one thing Mr. Witherspoon might have observed, which is not surely an indication of bad wages or unsound condition—the well-kept gardens attached to the cottages, in which many an old-fashioned flower is cherished, and where vegetables and

small fruit sufficient for the use of the family are produced. I am convinced that in this neighbourhood there is not a labourer who does not, taking the year round, earn £1 a-week, besides what the women and children earn by the not very laborious work of Hop-tying and other matters connected with our peculiar cultures. I was in the north lately, and saw a good deal of bad farming and bad cottages, but I should be sorry hence to infer that this is the normal condition of the counties through which I passed.—D., Deal.

SELF-FEEDING FURNACE FOR HEATING SMALL GREENHOUSES.

HAVING noticed inquiries as to heating small greenhouses, I venture to submit to my brother readers a section of a self-feeding furnace, which will be found effectual and economical. I built the original three years since, and have proved it to work sixteen hours, and even more, with one charge, at a regular heat, using only the cinders and refuse from the dwelling-house.

Description of sketch, which is drawn half an inch to a foot. A, Level of stokehole; b, ashpit; c, furnace; d, flue; E, hopper; F, bridge severing hopper from flue; G, furnace door; H, hopper door; I, damper closing front of ashpit (a plate of iron, with circular regulator in centre); K, sill and frame of house; L, stones, &c., retained in place by bricks set on edge, forming the lower strata of a hotbed for striking cuttings; L, end wall of house. The arrows show the course of the air, which, prevented by the door H from passing through the bulk of the fuel, seeks the flue as the easiest means of exit, and thus the fuel, slowly passing down the hopper, is consumed only on reaching the grate. There is a damper in the chimney outside the house, to assist the ashpit damper in high winds.

The fire, when thoroughly alight, is pushed to the back of the grate, the furnace door closed, and the hopper filled with fuel; the only attention then required is an occasional raking of the ashes through the grate by means of a hooked rake passed between the bars of the grate from the ashpit; the furnace door is only opened about once a-week to draw clinkers.

The size illustrated, with 10 feet of flue, heats a house of about 500 cubic feet contents, but sheltered from north and east winds.—G. W. G.—(*English Mechanic and World of Science*.)

OLD FRUITS AND VEGETABLES UNDER NEW NAMES—THE NEW STRAWBERRY DWARF TOMATO.

I HAVE waited for some weeks for an abler pen than mine to expose the untralesmanlike manner of sending out the Emerald Gem Pea. It reminds me of the anecdote of the parson who preached a sermon, and asked one of his hearers how he liked it. "Oh!" he replied, "I have admired it these forty years." Just so with the Emerald Gem; I have known and approved of it these forty years under the name of Kendall's Superb. That I might be certain of its identity I brought some old gardening friends to look at it, and they instantly recognised it as an old favorite. It is deserving of all that can be said in its favour, but I think it is too bad to palm off an

old thing as a new variety at a price which ought only to be attached to really new and improved varieties.

Some years ago a friend of mine sent me from Mansfield, twenty Peas by post, called Stewart's Paradise. I sowed them and saved the finest pods for several years, till their original size and appearance were very much improved, so that my friend could scarcely believe they were the same variety. Well, they got into a neighbouring seedsman's hands, who called them — Prolific. I instantly on view recognised them, and asked him if he was growing Stewart's Paradise Peas. "No," said he, "they are — Prolific." I replied, "You obtained them from one of your men." He was obliged to confess the truth, and then he changed their name to — Eschells," which synonymy they are known by at present until they get another.

Again, having read a good account of Princess of Wales Pea, I got a neighbouring seedsman to obtain some from London. These proved equal to description, and became very popular under the synonym of — Conqueror. I think it is very wrong to mislead people by giving things new names, but it is dishonest to charge the price of new varieties for old ones.—JOSEPH BURGESS, *Knutsford*.

THE answer to the "INTRODUCERS'" inquiry, "Wherein lies the deception?" must be patent to all. Permit me, however, to ask them if it is consistent with their views of fair dealing to call such an old and well-known fruit as the Cape Gooseberry a new Tomato, thereby inducing the public to purchase as a novelty that which it had so long cultivated.

Wherein lies the novelty of application? For many years it has been in general cultivation solely for its fruit, which is eaten as dessert, and also preserved as a jam, which is much esteemed, and I fail to see that those who term themselves its introducers propose to do more with it. In the supplement to Johnson's "Gardeners' Dictionary," it is stated that *Physalis edulis* (or catalpa Cape Gooseberry), is a native of South America, introduced into this country in 1773, just a hundred years ago.—E. LUCKENST.

I HAVE to thank Mr. Luckhurst for putting us on the alert against the "New" Strawberry Dwarf Tomato, and I at the same time take the opportunity of protesting against such attempts to pass off old things as novelties merely because they appear as such in American catalogues. In this country we generally suppose that nursery and seeds-men know their business and act upon their knowledge. Suppose an American seedsman were to offer seed of the "New Green Gage Tomato" (*Solanum tuberosum*), would "the introducers" be justified in offering this to their customers as new, merely because the American said that Potato berries might be used as Tomatoes? I think it would be better if some of our seed-men exhibited more judgment and less eagerness in the introduction of novelties.—AMATEUR.

WALES AND WELSHMEN.—No. 3.

WHILST I am writing these notes Mr. Justice Keating has been here for the purpose of holding the assizes, and he made this remarkable and, probably, unparalleled address to the grand jury:—"Gentlemen—your duties will consist of listening to the gratifying announcement that there is no prisoner for trial at the assizes. I have received a return of the state of business at the assizes corresponding to the present during the last three years. From that return I find that in 1870 there was but one prisoner for trial, against whom no true bill was found; in 1871 there were four prisoners for trial, three of whom were found not guilty; in 1872 there were no prisoners for trial; and in 1873 there is once more a blank calendar. This is a state of things reflecting the greatest credit not only upon the magistracy, clergy, and all concerned in the preservation of the peace in the county, but also upon the population at large. I have the satisfaction of stating that this gratifying condition of things is not confined to Anglesea, for as far as my experience has hitherto gone, this immunity from crime appears to be general in the Principality. Up to the present time I have had the honour of bringing Her Majesty's commission into four counties, and in all of these I found only four prisoners for trial, the offences with which they were charged being so slight that I deemed justice would be satisfied by passing a sentence of fourteen days imprisonment upon each.

This affords a glorious contrast to the characteristics of four centuries ago when one of our nursery rhymes was composed

and justified. In those days the Welsh retained possession of the mountains, and the English of the lowlands. When, says Mr. Flavel Edmunds, opportunity served or provisions became scarce, the Welshmen made a foray upon the herds of the English and hurried back with their booty to their fastnesses. The nursery rhyme records this in

Taffy was a Welshman,
Taffy was a thief,
Taffy came to my house
And carried off my beef.

By-and-by retaliation was attempted—

I went to Taffy's house,
Taffy wasn't at home.

He was too prudent to await his visitors when inconveniently numerous, but whilst they were seeking for him he sometimes made a wide detour, came down upon the English homesteads left unguarded, and carried off the remainder of the herds he had previously thinned, or, as it is rhymed,

Taffy came to my house
And stole a marrow bone.

That is, all that remained worth taking.

Since last writing I have had more opportunities of seeing and hearing of the gardening in the island. At Baron Hill and other high-class places it is very superior, but of these I shall speak and illustrate in future communications. Among the agricultural labouring classes the absence of gardening—rather should I say of gardens—is most lamentable. There is no want of a fondness for the culture of plants, both ornamental and useful, but space for useful gardening is rarely attached to the cottages. There are frequently plots in front of them, each of which plots might be covered with a tablecloth, and in these you see huge bushes of the *Fuchsia coccinea*, Rose bushes, Nasturtiums, and Pinks. In the windows are pots of praiseworthy Geraniums, many varieties of the double among them; *Calceolarias*, and *Minulules*. I saw one old dame sitting paralysed before her cottage door, with some especial pet Geranium in her lap. Such tastes might be expected among those among whom crime is so rare, but it is a taste that lingers even among the deprived of cities, and is still more ardently fostered by those who find it a solace in poverty. "My Pinks," was the pathetic comment of a permanent inmate of a workhouse, "My Pinks came from the garden I once had;" and a letter now before me from a lady at Ipswich says, "I was in the workhouse this afternoon, and there one woman who cannot leave her bed had made quite a pretty little garden on the window-sill by her side. It was only small bottles and jars filled with such flowers as she could obtain, but they were prettily arranged and set upon little mats which she had made. This was not much, but evidently her window-sill is a solace to her, and in the workhouse there is very little to make life at all bright."

Of useful plots attached to the cottages, and to the shame of the landed proprietors I record the fact, there are but few, and these very small. It is a disgrace to them, because they must know if they thought at all what would improve the home comfort of their workmen, that a garden capable of yielding a Cabbage, an Onion, or a mess of Beans to the support-pot, is as valuable to the cottager as the better-stored larder is to his employer. It is true that the farmers are accustomed to let out a field in plots to their labourers on the conditions that they manure the plots, plant them with Potatoes, and keep them well weeded. But this is to secure a benefit to the farmers, for such manuring, forking, and hoeing as is needed for the Potatoes prepares the field for the Wheat crop. To obtain the requisite manure the produce of the labourer's pigstye, if he owns one, is appropriated, and, in addition, the horse droppings on the roads, which you see arching scraping and sweeping-up.

It is a fact that wherever in Anglesea any part of a parish boundary touches the sea shore on that part the church stands. Probably this was because in Roman Catholic days the ecclesiastics found a supply of fish most desirable; but as lay residences were necessarily attracted to the vicinity of the church, they were at the same time attracted to the most exposed and least fertile spots on the island. One parish about six miles from Beaumaris is remarkably so. I refer to Llanddona. Here the church is little more than a stone's throw from the rocks, and the ways to it—they do not deserve the name of roads—are so precipitous and rough from rock points stubbling their surface, that no carriage can proceed further than to within a mile from the church. Yet even here in the rectory garden the Lichen crop, and the Apple trees

are most healthful and prolific. Their culture, therefore, should be encouraged, and landlords would do well for their own interests to insist on their cultivation. You would aid in effecting this by promoting the circulation of Mr. Lea's little volume in this island.* How much such cultivation is needed requires no other evidence than the deficient supply at Beaumaris, and that supply is of bad fruit and vegetables. This is explained by the fact that there is not a market gardener, nurseryman, florist, or seedsman in the whole island, and the greengrocers receive their supplies from Liverpool! I except from my condemnation the Potatoes, which are the best possible, and are evidence to the success that would attend the culture of other garden produce.

Mentioning Llanddona reminds me of its most energetic and praiseworthy rector, the Rev. Peter Jones. The old church was unsightly, devoid of the slightest architectural pretensions, and was some two years ago in such a dilapidated, not to say discreditable and unseemly condition, as to call for immediate attention, otherwise it would in the course of a very short time have degenerated into a tumble-down structure, such as that ruined edifice misnamed the parish church, which at present disgraces the adjoining parish of Llangued. The old fabric boasted considerable antiquity, and its foundation is traced so far back as the seventh century, tradition ascribing its erection to the pious St. Dona, the son of Selyf. So the rector resolved to have a new church, and he affords one more instance in support of my life's maxim—a clear head, a strong arm, and a good heart, expunge "impossible" from their owner's dictionary. The new church was opened for divine service a few days since. The works, which occupied about eighteen months in completion, were done by day work under the superintendence of the rector, to whose indomitable perseverance and energetic efforts the erection of the new church is solely due. Mr. Jones, in addition to acting as secretary and treasurer of the building fund, furnished the plans, acted as clerk of the works, and superintended the construction of the building from its very foundations. In addition to working single-handed in this good work, he had to depend a great deal upon extraneous pecuniary assistance, Llanddona being a not over-wealthy and very thinly populated parish. In the face of great difficulties and obstacles which would have disheartened many parish clergymen, he has succeeded in erecting a pretty and substantially-built church at a cost barely exceeding £600, and in opening it with a very trifling incubus of debt still remaining. His appeal for pecuniary aid was very liberally responded to, Sir Richard Bulkeley headed the subscription list with £50, Captain Verney, R.N., contributed £30, and Lord Penrhyn, whose name figures prominently in every fund for the erection or restoration of a church in the Principality, was also a liberal donor. Still, there is a small debt remaining, and any of your readers will do worthily who send a contribution directed to the rector, "Llanddona, near Beaumaris." It might be sent in postage stamps now that that thoughtless requirement about registering has been rescinded.

The new church is about five miles from Beaumaris, far off the beaten tourist track, and about a mile beyond the village proper of Llanddona. It occupies the exact site of the old fabric, and nestles at the foot of a mountain on the east side of Red Wharf Bay, commanding a splendid view of the wide expanse of sea, and the rugged mountain scenery, and its widely extending sands are firm and stoneless.—G.

ALLEGED NEW POTATO DISEASE.

A NEW Potato disease is described as having made its appearance near Jena, differing from the one commonly known in its directly attacking the tubers, and not the leaves. The tuber becomes covered by a purplish felt, which is the mycelium of a fungus. The skin of the Potato is sometimes apparently not penetrated by the mycelium, the contrary being the fact in other cases. In the latter event, the tuber becomes completely destroyed by a cancerous disease. The fungus belongs to the genus *Sclerotium*, and according to Professor Holliss, the remedy will probably be the same as in the ordinary Potato disease—namely, the selecting of early kinds, using only mineral and no animal nor vegetable manures, and with a careful selection of the best adapted soil. The Rev. M. J. Berkeley, the eminent fungologist, has lately

* The name of this volume is "Small Farms: How they can be made to answer by means of Fruit-growing."—London, Journal of Horticulture Office, 171, Fleet Street.

announced that this is the well-known "Copper Web," which in some years is very destructive to Asparagus, Mint, and other crops, and has been known, to some extent, to attack the Potato. It is figured in Tulasne's "Fungi Hypogaei," under the name of *Rhizoctonia*.—(*American Paper*.)

ROYAL HORTICULTURAL SOCIETY.

August 6th.

THE Show on this occasion was of very limited extent, by no means filling the western conservatory corridor; but as a set-off it was well arranged, and the Phloxes and Orchids made an effective little show for this season.

Phloxes formed the main feature of this Show, and of these Messrs. Downie, Laird, & Laing staged a remarkably fine twelve in 10-inch pots, and took the first prize. Among the varieties were Bridesmaid, white, shaded with lilac; Philippa Penglass, fine lilac rose, carmine centre; Monsieur Domage, M. Malet, Madame Domage, Lohair, salmon red; Madame Dombain, M. de Launay, John Laing, and Marguerite de Turenne, lilac. Mr. Ware, Hale Farm Nursery, Tottenham, was second with, among others, fine examples of Countess of Breckinridge, magenta; Ada, deep rose, crimson eye; and Mrs. Laing, lilac. Mr. Ware also sent a collection chiefly consisting of seedlings; but from Messrs. Downie & Co. came a far finer collection, for which an extra prize was given. There were no amateur exhibitors.

Petunias, for which there were four classes, had not a single representative, and of Cannas there was but one collection. This was exhibited by Messrs. L. G. Henderson & Son, Wellington Nursery, and consisted of large plants of Abundance, with red bronze-veined leaves; Red Lantern, deep green; Musafolia hybrida, of a brighter green; Princes de Nice, yellow-flowered; Schubertii; and Reera superbissima with dark bronze veins and suffusion. The best six Hydrangeas were excellently-bloomed specimens of the common kind, shown by Mr. Aldous, Gloucester Road, South Kensington.

Of miscellaneous subjects Mr. Ware, of Tottenham, sent a group of herbaceous Lobelias, but with the majority of the flowers only partially expanded. A first prize was awarded to Mr. Denning, gardener to Lord Londesborough, for a collection of Orchids, including splendid specimens of *Saccolabium Blumei*, with seventeen spikes; *Epidendrum vitellinum*, with thirty-eight flowers; *Oncidium macranthum*, and *Disa grandiflora*, all of which had cultural commendations; also a fine *Thunia alba*, *Saccolabium Blumei* superbum, and *Cattleyas*. From Mr. Aldous, Gloucester Road, came a miscellaneous group, which took an extra prize; Messrs. P. & A. Smith a very fine collection of Balsams, both as regards size and colours of flowers; and from Mr. Ware, Tottenham, a dozen Pentstemons in pots in very good bloom. From Mr. C. Turner, Royal Nurseries, Slough, came splendid stands of Carnations and Picoetes, of which Carnation King of Yellows, large, canary yellow, had a first-class certificate. From the same exhibitor came also a splendid stand of Verbenas, Prince of Wales, crimson scarlet, being especially effective. Messrs. S. Dixon & Co., Amlurst Nurseries, Anton Street, Hackney, again exhibited their fine new double-flowered dwarf Lobelia; and Mr. Maurice Young, Milford Nurseries, Golding, his beautiful Golden Chinese Juniper, which had before been certificated.

For the best dish of early Plums, Mr. B. Porter, gardener to Mrs. Benham, Lion Lodge, Isleworth, was first with Early Morocco, and Mr. Parrow, gardener to G. Batters, Esq., Enfield, second with Jaime Hative. The best collection of Gooseberries came from Mr. Walker, nurseryman, Thame, who had some very large fruit; the second best from Mr. Record, gardener to J. Whatman, Esq., M.P., Vinters Park, Maidstone, and the third best from Mr. W. Martin, Sherrinbury, Hurstpierpoint. Mr. Clarke, gardener to J. Hall, Esq., Sutton, and Mr. Hepper, gardener to C. O. Leonard, Esq., Acton, also competed. The first prize for the six heaviest Gooseberries went to Mr. G. Kirkland, Bletchington, Oxon, weight 5 ozs.; the second to Mr. Walker, Thame; the third to Mr. Kirkland, Albion Nursery, Stoke Newington; and the fourth to Mr. Tomkins, Bletchington.

FLORAL COMMITTEE.—W. B. Kellock, Esq., in the chair. The subjects exhibited on this occasion were not numerous, but a good number of certificates were awarded. One of the first-class went to Messrs. Veitch, of Chelsea, for a charming white *Lilium* named Philippeum, with a tube nearly 6 inches in length; also for *Olearia Haussii* in a basket, but lifted from the open ground, densely covered with white sweet-scented flowers—indeed a mass of blossom. *Cypripedium Sedeni*, a hybrid between *C. longiflorum* and *C. Sehmii*, was also certificated, and is a pretty lively-coloured kind. A first-class certificate was awarded for *Begonia* William Spinks, a cream yellow-flowered variety, raised at the Society's garden at Chiswick.

From Messrs. J. & C. Lee, of Hammer-smith, came several examples of trees and shrubs. *Robinia pseud-Acacia* a tree with beautifully golden-tinted leaves, had a first-class certi-

ficate; also *Prunus variegata* with white variegated foliage, and *Alnus glutinosa laciniata*, with broad rather deeply-lobed leaves. *Ligustrum lucidum angustifolium* with, for a Prize, very long leaves, and a variety of the same species called tree-color, with much broader and shorter foliage, margined with yellow and edged with rose, were also exhibited. The latter is a very pretty variety.

From G. F. Wilson, Esq., Weybridge, came a fine double Tiger Lily, called *Lilium tigrinum erectum*, together with photographs of varieties of *Lilium longiflorum*. Mr. Ware, Hale Farm Nurseries, sent collections of perpetual Carnations, and an excellent lot of seedling Pentstemons; whilst from Messrs. Wood & Ingram, of Huntingdon, came stands of seedling Carnations and Picoetes. The Rev. Lord Hawke exhibited a number of new Hollyhocks, of which his name alone is a guarantee for their quality. First-class certificates were awarded for Mrs. Chater, primrose with an orange-tinted centre; Catherine, pale salmon; Red Cross Knight, red and maroon; and Octavia, rose. From Dr. Denny, Stoke Newington, came *Pelargonium Jessica*, deep scarlet; from Mr. Douglas, gardener to P. Robinson, Esq., Womersley, well-grown Cockcombs of a good strain; and from Messrs. Dicksons, Waterloo Place, Edinburgh, some excellent early-flowering Phloxes, much the worse for their journey, of which we especially noted Edinburgh Castle and Callar On. Mr. Rowe, The Bakery, Rochester, sent a large specimen of *Polyporus squamosus*.

PRIZE COMMITTEE.—Alfred Smee, Esq., F.R.S., in the chair. Mr. H. J. Hardy, Bures, Essex, sent Hardy's Pedigree Windsor Beans. In reference to these, it was decided that all vegetables before receiving certificates be grown at Chiswick, on the recommendation of the Committee, except where a decision can fairly be made. Mr. William Bull, King's Road, Chelsea, sent a Cucumber, called Excelsior, which was considered past its best. Messrs. Monro & Wilkinson, Potter's Bar, sent specimens of a Cabbage, called Little Heath, which was considered a good sample of the Fulham or London Market, but not worthy of a new name.

Mr. Henry Plummer, gardener to R. Thornton, Esq., Cannon Hill Park, Merton, sent two Queen Pines, a Smooth-leaved Cayenne, and an Abayah. The last being a variety unknown to the Committee, it was cut. This is a medium-sized conical fruit, of a deep yellow colour, and prominent pip. The flesh is deep yellow, very juicy and sweet, lacking acidity. The Committee were of opinion that this is Havannah. Mr. Baker, gardener to A. Basset, Esq., Sister House, Clapham, sent a distinct-looking Pine Apple without name. It was imported from the West Indies four years ago, and as it was not quite ripe it is to be seen again. Messrs. Monro & Wilkinson sent Little Heath Melon, good specimens of the third crop borne by the plants.

Mr. Bowman, gardener to Sir Joseph Hawley, Leybourne Grange, sent a hybrid Melon with red flesh, which was very inferior in flavour. Mr. Cox, of Reddih, sent a dish of Pears, somewhat resembling Doyenne d'Été, but inferior in flavour. They were from an old tree grown in the neighbourhood of Penhurst under the name of Early Milton. Mr. Clark, gardener to J. M. Robertson, Esq., Rochester, sent a dish of Citron des Carmes Pears, and also a dish of White Joaneuing and Red Margaret Apples. Mr. Earley, gardener, Valentines, sent a collection of fruit, consisting of a dish of each Apricots, Apples, and Pears, one of Early Orleans Plums, and fifteen dishes of Gooseberries, for which a letter of thanks was awarded, and a cultural commendation was awarded to the Apricots. A letter of thanks was awarded to G. F. Gregory, Esq., Addison Road, Kensington, for a dish of well-kept Apples. Mr. William Paul, of Waltham Cross, sent a bunch of a new Grape, called Seedling Sweetwater, which Mr. Paul was asked to give an account of as regards its growth and bearing.

Mr. J. Henson, gardener, Newark, near Peterborough, sent a seedling Gooseberry, called Henson's Seedling. This is a decided acquisition, being a fruit of good size, and both in that respect and in colour not unlike the Red Warrington, but the flavour partakes very much of the Red Champagne, and is quite rich. It is a very fine highly-flavoured Goodberry, and, judging from the spray laden with fruit which was exhibited, it has the appearance of being an abundant bearer. This was awarded a first-class certificate.

ADVANTAGES OF HOEING.

1. The loosening of the soil in the operation of hoeing is beneficial to the plants—as much as the destruction of the weeds, or more so.

2. Moisture abounds in the atmosphere during the hottest months, and is absorbed and retained most abundantly by a soil which is in the most friable state. Prof. Schubler found that 1000 grains of stiff clay absorbed in twenty-four hours only thirty-six grains of moisture from the air, while garden mould absorbed forty-five grains, and the top soil absorbed seventy-six grains.

3. Then, again, pulverising soil enables it better to retain the moisture absorbed.

4. The soil, in order to be healthy and active, must breathe. A light porous soil admits the air, and thus it is fed and greatly invigorated by the atmosphere.

5. The sun's rays heat a hard soil much quicker than a loose one, and the hotter the soil is so much greater will be evaporation from it. So that a hard soil is deprived of its moisture much sooner than one of a loose texture.

6. The roots of plants can find their way through a moist loose soil in search of food much better than they can through a hard dry soil.

7. The soil that has been ploughed well and then kept loose near the surface by the action of the hoe, will receive and hold the rain water that falls, while a hard soil will allow most of it to run off into the valleys and streams as it falls.—(*New England Farmer*.)

ORNAMENTAL PLANTING.—No. 6.

RHODODENDRONS and their allies are associated under the convenient title of American plants. From the great and peculiar beauty of the entire class, but more especially of the Rhododendrons, they are certainly most worthy to hold a superior rank to shrubs in general; but it is questionable whether the practice of separating them from other shrubs in the catalogues has not contributed materially to the very prevalent but erroneous impression that, in order to succeed in their culture, a peculiar mode of treatment and costly preparation of the soil are necessary; and it is also probable for the same reason that we so seldom find mixed groups or shrubby borders enriched and beautified by the presence of any varieties of this lovely genus. What contrast could surpass in beauty or effect the deep rich crimson trusses of Rhododendron John Waterer with the profuse clusters of the deep golden yellow flowers of Berberis Darwinii? Not that I would often plant two such striking objects side by side, but rather sufficiently near each other for the contrast of rich colours to produce its due effect, which would be much heightened by the intervention of a Conifer with deep green foliage, such as Libocedrus decurrens or Arthrotaxus selaginoides. Then there is a host of other excellent kinds, with other shrubs, all equally valuable for mixing—ranging in colour from a deep purple through all the various shades of crimson, scarlet, pink, and white, all very striking and ornamental, forming a perfect treasury of objects rich and rare, surpassing almost all other shrubs in the bright and varied loveliness of the flowers that are produced in such profusion, and that never appear to greater advantage than in the setting of living deep green foliage, which from its ever-green character, beautiful disposal, and fine form adds so much to the value of Rhododendrons as decorative plants.

There are in a few gardens in this country masses of the famous old *R. ponticum* 20 to 30 feet high that are objects of rare beauty; and as it is quite within the bounds of possibility that the most robust hybrid varieties will in time become equally large, this important fact should duly influence our present and future planting arrangements. Well-formed specimens of even 12 feet high of such kinds as the pure white Mrs. Clutton, or the newer crimson and scarlet varieties, would form objects of such incomparable magnificence as it is hardly possible to conceive; and so in my advocacy for a more extensive use of plants of this class, I would urge upon those who contemplate planting, to afford space for a few select kinds as single specimens. Apart from that association with other shrubs which it is desirable should become more general, the practice of massing the various kinds in groups and borders by themselves is an excellent one, and the fine appearance of such groups during the flowering season is too well known to require one word of commendation at my hands. Some caution is, however, necessary in the arrangement of these masses, for however brilliant and dazzling may be the effect of the flowers, yet it must be granted that very much of the spirit and brightness of the scene fades with the flowers, and that the foliage, which alone is visible for so long together, is apt to appear somewhat tame and monotonous; hence the frequent attempts to introduce Hollyhocks, Lilliums, and Tritomas among them are sufficiently significant and expressive of how prevalent this feeling is. It is true we may relieve and brighten the effect, as we do with hardy Azaleas, Kalmias, and Ledums; but none of these continue in flower long after the others, and it must not be forgotten that it is of pure and simple groups of American shrubs that I am now treating. It seems to me, therefore, that the best remedy for this obvious defect is to introduce

groups of other shrubs sufficiently near and among them to relieve the monotony and sustain an interest in the scene by imparting variety, and by the production of flowers at a later period of the year.

In forming a Rose garden upon an exposed position where violent gales frequently swept across with great power, it became necessary to make a shelter to break the wind's force, so as to screen the tender growth of the Roses in spring. Now, I had seen various screens used for this purpose, but all of them were very formal, not at all ornamental; they were, in fact, just screens and nothing more, very efficient for shelter; but then, in forming a screen of living shrubs or trees, by the exercise of a little care and judgment it may be rendered as ornamental as it is useful; and so in the instance to which I allude, instead of a row or two of shrubs of no particular interest, groups and belts of American shrubs, interspersed with a few choice specimens of Conifers standing singly upon the turf, were introduced with excellent effect; for as the Rhododendrons began to fade, the clumps of Kalmia began to expand into beauty, the persistent flowers lingering on till the first opening Roses gave promise of the rich display to follow; and thus by this arrangement a scene full of brightness and beauty was secured for a much longer period than would have been possible from the use of either class separately.

Very interesting and pretty beds may be made with many of the dwarf-growing American plants, such as the Kalmias, Gaultherias, Ledums, Menziesias or Daboecias, Pernettyas, Daphnes, Ericas, Andromedas, and dwarf Rhododendrons, and a group of these will be included in the following arrangements:—

Mixed group of Rhododendrons (*fig. 1*).

A similar arrangement to the foregoing would answer well for a bank of Heaths, or there might be three or more plants of each kind together in little clumps, so as to impart a greater breadth of colour; but whatever style be followed, it is desirable to introduce the lovely *Erica carnea* to brighten the bed

with its gay flowers long before the other varieties come into bloom.

A circular bed of Heaths, each ring of a distinct kind surrounding a central group (*fig. 3*).

Another very beautiful bed may be made by surrounding a mass of *Andromeda floribunda* with a broad edging of *Erica carnea*, the clustering white bells of the *Andromeda* appearing in most beautiful contrast with the bright pink flowers of the Heath. Then, again, a group of one or several kinds of *Rhododendrons* has a pleasing air of neatness and finish when surrounded with an edging of *Ledum latifolium* or the pretty Japanese *Azalea amena*. Many other pleasing combinations may be wrought out with little trouble, for the store of materials for the work is so rich that all may find some kinds to please and interest them.—EDWARD LUCKHURST.

SLUGS.

THESE pests are too numerous and common everywhere, and with all our care they will find their way even into our greenhouses. Last year I visited the gardens of Earl Somers in Herefordshire, and was told of a method practised by the gardener there for ridding the ground of slugs—at least, of thinning them to a great extent. We all know that quicklime causes them rapidly to disperse, but I have found that it often sends them to where of all places we would not wish to see them. The plan is to finish as many of them off as possible, and to be conclusively done with them. Well, the gardener managing Lord Somers' grounds (Mr. Coleman) adopts the following method, which may be known to some of your readers, but it was new to me.

A lad is sent along all the walks of the garden each evening with a bag or bucket full of bran, and he places a handful of it on the borders, at every 8 or 10 feet or so, in a heap. Early next morning he traverses the same ground with an empty bucket, dustpan, and small broom. Bran is an article slugs are very fond of, and it seems to attract them from all around; the heaps are, therefore, found covered with them, often a complete mass. The lad then sweeps the whole into his dustpan, empties it into the bucket, and by the time he has finished his walk many hundreds, if not thousands, are thus captured. A week or two of such work, or even a day or two now and then, must be the means of saving a great deal of our garden produce.

I would recommend that when collecting the slugs a little salt and water be in the bucket, which will effectually prevent the escape of a single member when captured, as the salt causes them to sicken and die at once. Will some of your readers please try this simple affair and report?—J. HUIE.

THE GREEN ROSE.—I am sending you by this post a specimen of the bloom of one of my green Roses, which I think you will admire. We have had the plant from which I cut the bunch of flowers for about sixteen years; it was moved this spring. The green Rose was mentioned in THE JOURNAL OF HORTICULTURE some months ago, and as it is uncommon, I thought you might be interested to see such a fine bouquet of flowers on one stem.—ELIZA C. BISCOE, *Holton Park, Oxford*.

The specimen is a very fine one, and contained twenty-two flowers.—EDS. J. OF H.]

SOILS, THEIR VARIETY AND USES IN CULTIVATION.—No. 2.

STIFF soils usually contain but little sharp gritty matter or sand, and the unctuous mass clings together in such a manner as to be almost impenetrable to the roots of plants and the tools of the cultivator. They are invaluable to the brickmaker; but the husbandman complains of their adhesiveness and of water not percolating freely through them. They are, however, capable of considerable improvement, especially by draining, although the effects of the latter are not always immediate, for a tenacious clay is not converted into a friable fertile soil all at once, and a wet, adverse season tends to undo what has been done before.

Of heavy soils some have as a substratum a yellow tenacious clay, through which water finds its way very slowly; others a clay mixed with a sandy gravel; others, again, a clay sometimes forming a blue mass of great depth with comparatively little water, and not so adhesive as always to retain the shape in which it is excavated. Clay of this kind is of little value as

Fig. 3.

| 2. cinerea coccinea. Bright pink. | 5. <i>vagens alba</i> . Very fine white. |
| 3. atro-purpurea. Deep purple. | 6. mediterranea. Purple. |

a fertiliser except for light sandy soils, to which it gives more solidity, but it is more remarkable for the great depth to which it extends. Clays of other kinds also abound in places, and all tints of grey are represented; some clays of this hue are the most useful for cultivated plants. In many instances lime may be advantageously employed in diminishing the adhesiveness of clay soils and rendering them more productive; but to the gardener who has a choice of soils I would not recommend one of a very stiff nature except where long droughts prevail, and scarcely then.

Let us now turn to some of those high dry moorlands of which Derbyshire, Staffordshire, and the north-western counties, afford such numerous examples, a considerable breadth also occurring in Surrey and on the south coast. There the hilly districts present two or more kinds of soil, to a certain extent differing from each other. The dry, black peaty skin of thickly-rooted matter of heath and fern is often desired for the potting-bench, as Heath and Azaleas, as well as several other plants seem to luxuriate in such a soil; but it is not well suited for cultivation, for it is often shallow, with a hard stony bottom, and on high naked situations deficient in shelter and altogether unsuited for cultural purposes. Patches of it, however, are found on a lower level and exhibit great fertility after cultivation, and have less rooty matter amongst the soil than occurs at greater elevations.

I will not here enumerate the plants which a peaty soil from a dry upland heath is said to suit, but I may remark that for many years it was thought to be the only one in which Rhododendrons would succeed, but they have been found to thrive in soils that to outward appearance bear little resemblance to peat, still there are many choice plants for which this is indispensable in pots.

The above dry upland peat must not be confounded with that obtained in the morasses at the base of the hill, which is often pernicious to vegetation—perhaps containing iron, which I have known to kill Rhododendrons; but such peat, after having been cut for fuel, left for some time exposed to the weather, and then immersed in a manure tank, may often be used with advantage for the same purposes as fibrous peat; but care ought to be taken how it is used, for it frequently does much injury.

Resembling in some degree the bog soil just alluded to is that which occurs by the sides of tidal rivers, where large tracts of level land have been overflowed by high tides, rendering the land like bog in colour, but differing from it owing to the water not being impregnated, as in the case of bogs formed by springs, with the substances through which the water passes before reaching the surface; and in the two cases a different kind of herbage prevails, so that the same crops can hardly be expected to thrive in each alike. Another distinction often exists. The marsh land by the sides of large rivers, or where the tide has overflowed at some former time, often contains more sand than the inland bog; and after cultivation for a series of years this sand forms an important element in the composition of the soil, as it exhibits itself in greater abundance after the vegetable fibre which once bound the whole into a mass has perished, and some very productive land is often the result.

Taking next another description of soil—that of a sandy district, where rain helps to make the ground and roads cleaner rather than dirty by consolidating the sand. Such soils are not unfrequent, and have these advantages, being more especially useful where rain falls often and in great quantity. Of their value for garden purposes little need be said, as much depends on the character of the season. Some crops luxuriate in sand—for instance, Asparagus where it has been liberally assisted with manure; and it is nowhere cultivated to greater perfection than in some of the sandy plains that border our tidal rivers. In dry sandy districts, again, there is often a soil that will almost blow away with a brisk wind, but underneath many such tracts there is marl at no great depth below the surface, and this can be dug up and spread over the field in sufficient quantity to meet the requirements of vegetation. Marl and marl pits are common enough in many places, and they have played an important part in husbandry.

Perhaps the most fertile of all soils are those formed by the alluvial deposits at the sides of rivers beyond the reach of the tides, and of ordinary fresh-water floods. Most rivers have a bordering of this kind of land in some part of their course, and on it occur the richest of our pasture and the most productive of our arable land. There the soil is deep, of rich earthy matters, and in all respects capable of supporting vegetation. Land of

this kind often gives us the earliest and certainly the most abundant crops, and it is well adapted for most vegetables; Celery, Rhubarb, Lettuce, and even Asparagus, doing remarkably well. Some of the best market gardens in the kingdom and not a few private ones are placed in such situations; their great drawback is their liability to suffer from early and late frosts, and in midwinter the frosts are often more severe than in more elevated sites.

Flinty gravels occasionally occur in districts where water is scarce; they are not at all enviable soils, and yet in favourable seasons good crops of corn are often reaped, even when the stones may be shovelled up in cartloads all over the ploughed ground. These stones, be it remembered, are not without their uses, and help to keep in what moisture there is in the land, and help also to keep it open. It is partly due to the stones that the soil does not harden into a solid impenetrable mass; for in many cases where angular or rounded flints abound in such quantities the intervening substance is a much stiffer and more adhesive material than it is often thought to be. The gardener, at all events, ought not to select a soil of this description, at least not the scalp of such a hill, but the valley may often be better, in consequence of the best soil being washed down by the rains; but dry hot seasons affect such lands severely, and in some places the absence of water is a great defect in domestic as well as cultural matters.

There are many other soils of an intermediate character comprising portions of two or more of those described, while there are some to which it would be difficult to give a definite character; amongst them are some of the shallow clayey soils resting on a shaly gravel—such soils are not generally productive. There is also a sterile gravel now and then met with of a bright yellow colour, evidently one of the worst to deal with, and patches of this in a naked condition often occur in waste places without exhibiting a vestige of vegetation, as on some of the moors of Derbyshire and Cannock Chase, in Staffordshire. Such soils require more time to render them fertile than would pay the cultivator to make them so, and the epithet barren applies to them; yet they are not absolutely so, for seeds will vegetate upon them, but they cannot sustain vegetable life for any considerable time.

Let us now suppose ourselves to be going from London by rail; we have not to travel far before we see several of the soils previously referred to, and a glance at the character of the crops, coupled, of course, with other considerations, will in many instances convey a good idea of what the soil really is. Most of the land near London may be said to be in an artificial state of cultivation—*i.e.*, it has for many years been so highly manured that the original character of the soil is almost lost sight of; but farther from town this result cannot so well be accomplished, and we have there the land in a condition more nearly resembling what it naturally is, and its productiveness may generally be estimated with some exactness by the character of the trees and hedges, and even the weeds. Nettles, notwithstanding the hostility most people bear to them, are one of the best indications of good land, much more so than Fern or Bracken. Crowsfoot is also a sign of good land; while wild Thyme and Daisies indicate inferior ground. The Ox-eye Daisy prevails in meadows of retentive soil, where it often blooms in a mass at the end of May or beginning of June in such a manner as to emulate the best-arranged flower garden. The scarlet Poppy in cornfields indicates a dry soil, while the purple Loosestrife is only seen in wet places, and amongst trees when in a condition of nature or nearly so. The Elm selects the best land, and is there capable of maintaining its supremacy, but on such land the cultivator has often a difficulty to rear the Spruce Fir, and has the mortification to find it often dies or becomes diseased at a very early age. Light land with a rather shallow soil more or less appertaining to peat suits the Scotch Fir best, while a calcareous soil is best fitted for the Beech, but both accommodate themselves to circumstances. The Oak is so often met with in soils of such widely different characters that it is difficult to define that which is best adapted for it. The light upland soils, where it is so often met with in a natural state in connection with Hazel, Birch, Maple, and other trees, is not the place where it attains the largest dimensions, yet every stiff soil does not suit it; a certain depth of soil for its roots to penetrate would seem to be necessary, and the best examples, I believe, are on rather stiff soils overlying a mixture of stiff loam and gravel.

Having extended my remarks to a greater length than was intended, I have only one further observation to make, and

that is what in the gardening world may sound something like heresy; nevertheless, I venture to ask this question, Are we right, when describing mixtures for growing choice plants, in recommending a mixture of peat and loam? I have given up the practice for many years and never use such a mixture. Soils intermediate in character between these two are plentiful enough, and where these can be had they are unquestionably better than the mechanical mixture. I am not sure that some other of our mixtures are not likewise open to objection. In conclusion I will remark, that a study of the soils which form the outer covering of our country is worthy of more attention than it has hitherto received.—J. ROBINSON.

THE CULTURE OF HARDY AND HALF-HARDY ORCHIDS.

It has often occurred to me that these plants should be more generally cultivated than is at present the case, more especially as many of them are, when well grown, scarcely less beautiful than the more expensive epiphytes of our Orchid houses. Terrestrial Orchids ought, as a general rule, never to be disturbed when making their growth, or in the flowering state; still I know from experience that many gardeners continually receive them from their employers or their friends, who happen to be travelling on the continent when these beautiful plants are in flower. The best way of collecting these plants is to mark them when in flower, and afterwards to remove them when the foliage has died off, and the tubers are thoroughly ripe and dormant. They (the tubers) should be carefully packed in moist earth or sphagnum during transit, and must be potted off as soon as received at home. The soil best suited for their requirements is strong fibrous loam, with a mixture of leaf mould and coarse sand; other species, as many of the Ophrys and Cypripediums, affect a chulky soil, or lumps of limestone may be broken and mixed with the fibrous or turfy compost. The pots should be well drained, and the soil pressed firmly around the tubers, after which plunge the pots in ashes, sand, or cocoa-nut fibre, in a cold frame, where they may remain all winter; all the attention they will require is to keep the soil moderately moist, nothing being more injurious than to let them get dust-dry. In a state of nature all bulbs and tubers get a copious supply of water during the winter season, or while they are at rest; and I have often thought that the reason many cultivators fail in growing these plants is, because they dry them off during the winter months. The pots should be protected during heavy rains and severe frosts, either by having the glazed lights drawn on, or an oil-cloth spread over the pit or frame in which they are plunged.

The foregoing instructions may be followed out in the case of rare or delicate continental species; but many of the British and American species may be planted out in the rock garden or herbaceous border, and will in most cases be found to succeed to perfection. One of the most beautiful of all hardy terrestrial species, *Cypripedium spectabile*, grows vigorously planted out in a peat bed on a cool clay bottom; while our only British species, *C. Calceolus*, grows best in a chalky loam, fully exposed to the east, but sheltered from the midday sun. In Messrs. Backhouse & Son's nurseries at York, these two beautiful species grow vigorously and flower profusely every summer, along with many species of Orchis and other continental Orchids. When these plants are grown outside, select a partially shaded spot well furnished with other herbaceous plants, and plant the tubers 5 or 6 inches below the surface; they will find their way through in due time, and will not suffer from the vicissitudes of the weather as they would if planted just below the surface of the ground. The contiguity of other herbaceous plants prevents undue evaporation from the soil in which they are planted. During winter a mulching of short litter, leaves, or manure, will protect them both from frost and cold rains.

I sincerely hope these beautiful plants will meet with every encouragement in our gardens, for amongst terrestrial Orchids there are many species not yet introduced to our collections that will bear comparison with the choicest epiphyte in point of beauty and fragrance. At the same time they may be grown without the unpleasant heat and extra labour required by tropical species.—B. (in *The Gardener*.)

DISEASE AMONG THE APPLE TREES IN THE NIAGARA DISTRICT.—The *Lockport Journal* makes some statements about a disease which does not appear to belong to the Apple "scare," so com-

mon about this season. Niagara is one of the largest, probably the largest, Apple-growing county in the State of New York. The above journal says a disease is prevailing in the orchards there that has destroyed many trees. It manifests itself in a curling of the leaves; the bark dies, then the body of the trees dies upwards about a foot from the ground; the disease also extends into the roots several feet, and kills the whole tree; the bark tightens and adheres firmly to the tree, and does not crack or peel. There seems to be no perceptible cause for fatality among the Apple trees; no grubs can be found nor anything else that would be likely to destroy. About fifteen trees in a splendid orchard belonging to Mr. Geo. W. Tower, in the town of Porter, have been attacked with this disease and killed. The trees were from fifteen to twenty years old. Several other instances in various towns are mentioned where fine, healthy Apple trees have been destroyed in like manner.

WHAT I KNOW OF PRUNING.

A THEORY as to pruning fruit trees, which has many recent advocates, is that the trees be suffered to grow as they please. To this there is earnest protest from careful cultivators. I doubt whether those who condemn pruning mean what they say—that is, that they would not cut out a single limb; if they do, it seems to me they do not understand the nature of trees. I suspect that they are beginners, and that when they come to know more they will change their views. I grant that the no-pruning theory has, nevertheless, some able advocates, men who really understand their business, but I doubt whether they would include Peach and all kinds of Apple trees. It is customary for the gardener in the Capitol Grounds at Washington to show Pear trees which, it is alleged, have never been pruned, and they look like it, but they bear well and are in a thrifty condition. It is to be noted that it is only Pear trees which are shown, so that the theory in this instance seems only applied to these trees. I grant that there are some varieties of Apple trees, slow growers and upright in habit, which need no pruning, and which probably will do better without it. But there are other sorts, having a bushy growth, which send out suckers and branches in every direction, and which, if permitted to have their way, will make a jungle of branches wholly unfitted for bearing fruit. If fruit does set it will be small, and being covered with foliage, will be without colour or flavour. To say that such varieties do not need pruning is absurd. It might as well be said that it is of no advantage to their fruit. What may be true of a variety that grows slowly and that makes dense hard wood even under high cultivation, cannot be true of a variety that grows like a weed, all its pores overflowing with sap, and the wood of which is spongy. Of this last class the Peach has a resemblance. So that the whole question resolves itself into a consideration of varieties, and the conditions of the case. There is no such thing as having one rule applicable to different conditions. A man must have judgment and sense. We may say, then, that the natural habit of a tree is to be considered, and that it should have its bent, providing it is not at the expense of fruit. Interfering branches, superfluous limbs and suckers never can be allowed, and whenever a good fruit-grower sees them he will cut them away.—AMATEUR (in *New York Tribune*.)

THE BEAUTIFUL AND USEFUL INSECTS OF OUR GARDENS.—No. 7.

I was afraid the meteorological tables published in Britain at the time of the Roman invasion, some 1900 years ago, were not very correct, or else our climate has considerably changed, and got much warmer (which is contrary to geological theories), otherwise the soldiers would never have thought of bringing with them the seed of a Nettle, presumably *Urtica pilulifera*. Their notion was, according to old Camden, that they could sow this plant, and as its growth was rapid, they would soon be furnished with an agreeable stimulating application, with which they could rub themselves when they found the cold weather trying, as they had been led to expect. Tastes differ; and we moderns find the sting of *U. pilulifera* a little too virulent to be preferable even to the endurance of some amount of cold. But, possibly the story is after all a *canard* of Camden's; historians have been known to lie.

But I have been led to connect this anecdote with insect life. The assertion that certain biting or stinging insects have, as part of the business of their lives, the duty of attacking us

so as to provoke us to cleanliness, is as old as many school books, and we take it for what it is worth. There is another theory, that certain of these seeming pests act somewhat on the principle of the Roman Nettles—they keep us up to the mark, and prevent our blood from stagnating, and drive it from the central organs of the body to the limbs, where congested vessels would do less harm. Who knows whether the sting of a wasp or the puncture of a flea has not saved some from sunstroke or fever? The idea is quite as plausible as that Tenterden steeple was the cause of the Goodwin Sands. Even the barb of the gnat, an insect we were discussing recently, and whose weapon is here figured, may be as wholesome as a surgeon's lancet, and give the species and its allies a new claim to be deemed useful visitants in a garden; that they are not without beauty we have already noted.

Among our garden visitants in the autumn is a lively and tolerably handsome moth, though it has no bright colours, and its claim on our admiration rests partly upon the fact that it exhibits the "poetry of motion," its attitudes in flight and in semi-repose being elegant, though not so grand as are those of others of the Hawk-moth tribe. This is well known to entomologists as the Humming-bird Hawk† (*Macroglossa stellatarum*), taking its English name from its rapid course on the wing, and the sound which frequently accompanies this. The Latin was suggested by the long tongue or proboscis, and, I conjecture, by the supposed attachment shown by the species to stellate flowers. This is an insect which has at times sorely vexed the souls of newspaper paragraphists, who have recorded its appearance under the heading, "Humming Birds in England," and have been compelled thereafter to explain the error into which they had unwittingly fallen. In some years, as in 1868, for instance, quite a swarm of communications have been sent to editors by persons in all parts of the country, describing this tropical phenomenon, because the insect was

Lancets and Tongue of Gnat.

more abundant than usual, and often exhibited itself in towns and about conservatories. Vain in many cases is it to assert what was the real nature of the marvel—

"Convince a man against his will,
He holds the same opinion still."

Did they not witness themselves the mysterious arrival of the interesting exotic, which stole upon them at the dusk, and poised itself over some fragrant blossom, "fanning" its tail, and then with a melodious hum dashed off to other flowers, its eyes all the while sparkling like "diamonds of the Orient?" And you would have them believe that this object was no bird, nay, more, actually an insect which had been bred on a bank not far from their own doors? Preposterous! Vain is it to show such persons specimens of the insect, unless, as may not often happen, you can secure the identical one they saw, otherwise they will still maintain that their's was "quite different." That there is a resemblance between the motions of this moth and that of the bird in question is granted, and the fact is noticeable that in some parts of France, where the children know, probably, little or nothing about natural history, they call this moth the "Bird-fly."

Macroglossa stellatarum—Caterpillar.

It has been questioned if *Macroglossa stellatarum* ever flies at night; and this is certain, that it prefers daylight, or at least twilight, for its aerial journeys, which are always taken with a purpose. In warm weather I fancy the moth is less inclined to be on the wing during the period the sun is high in the heavens; but on cool days, and later in the season, as during October, I have seen "Humming-birds" at all hours between sunrise and sunset, not "hawking" certainly, but busy in the pursuit of sweets. The insect divides its time between the flowers of the field and those of the garden; to some of the latter it is particularly devoted, as to the Jessamine and the Petunia. Specimens not infrequently enter houses, having been attracted to open windows by the plants placed thereat or growing up the walls. I do not think it often visits the sugary compound spread by insect-catchers on trunks of trees, though it has one odd taste, to which I called attention some years ago—viz., that it will visit and hover over the

Humming-bird Hawk Moth (*Macroglossa stellatarum*).

† We are indebted for the illustration to Hardwicke's "Science Gossip."
‡ This and the remaining engravings accompanying the present article are from Figuer's "Insect World," and have kindly been placed at our service by Messrs. Cassell, the publishers.

Macroglossa stellatarum—Pupa.

heaps of coals which are piled up in proximity to some railway stations. No doubt the moths are drawn to these by the organ of smell, but the fancied resemblance deceives them as they cannot get honey from coal, though we make it yield us sweet perfumes.

The Humming-bird Hawk moth is not an insect much given to vary in the perfect state, though we have two marked varieties of the caterpillar. The fore wings, of a deep brown, are crossed by wavy lines of a black shade, while the hind wings, much less in size, are orange, and darker in hue at the base and margins. The brown thorax harmonises with the fore wings, but the abdomen is curiously chequered with black and white. Both these are so well clad with hair that unless the insect is making its peculiar hum it may fleet past us, and we should not perceive it; by means of a tuft at the extremity of the body, aided by the vibration of the wings, the moth poises itself, and plies its long tongue very effectively. As late as November individuals have been seen at the autumn flowers yet surviving, but most have hibernated (or died off?) before that time. In Britain the species seems to be continued by the re-appearance in the spring of a part, if not all, of the

moths of the previous summer, which then deposit eggs on various species of Galium. By comparatively few persons, however, are they seen at the spring season, for which several reasons have been given, which need not be debated here. With the caterpillar one usually makes acquaintance in the month of August, or perhaps earlier, feeding on Galium mollugo more frequently than on any other of the Bedstraws. In the long-continued dry weather we occasionally have in the summer, it will be noticed that the Bedstraws die down very suddenly, except they may chance to grow in marshy places, and some of these caterpillars perish by the destruction of their food plant, for they are apparently unable to betake themselves to other species, except it be the Field Scabious. By a wise provision of Nature, however, they feed up with great rapidity when the weather is favourable, and I have had them at an early age, and in the course of a fortnight they have cast their skins two or three times, and increased rapidly to their full proportions. As in various others of the Sphinginae we find this caterpillar furnished with a pointed and straight horn at the tail, the use of which is not obvious; along the sides of the body we have not the seven oblique stripes seen in some familiar Hawk moth larva, but only two parallel lines, more plainly discernible in that type of the caterpillar where the ground colour is green. In another type the colour is brown tinged with pink. I have taken both of these off the same plant, feeding in such proximity as to leave one in no doubt as to their being descended from the same parent. This was in a lane near Chelsea, in Middlesex, where neither this caterpillar nor any choice insect is very likely to occur again, since the land is now a prey to the builder. The pupal state lasts only a few weeks at the most, and hence the cocoon is of a slight character, though sometimes large, being composed of leaves and stalks drawn together with silk in a careless way, and formed on the surface of the ground. It is made smooth at the base where the chrysalis reposes. This is rather singular in form, and so delicate that it will scarcely bear handling.

Anthrocera Filipendulae.

Anthrocera Filipendulae. Cocoon.

A smaller member of the Sphinx family (as constituted by Linnaeus) is an occasional visitant to our gardens in some counties. I have seen this species flying by dozens in some of the slopes of Kent, now and then resting on the wild Thyme, and afterwards with a rapid course, speeding about among the gardens on the edge of the road above, looking a charming object as the sun lit up its green and crimson wings, giving them a metallic lustre. The Six-spotted Burnet Moth, otherwise *Anthrocera Filipendulae*, has five relatives occurring in Britain, but this is the commonest of the genus. One writer on entomology remarks that the species flies heavily, and rarely during bright sunshine. This is scarcely correct in either particular, for though we notice them in little swarms clustering about the flowers like bees, they take quick though not lofty circuits on the wing, and very soon damage their plumage. These insects are as gregarious in the larval as in the imago condition, for we find the caterpillars feeding in companies, generally on the Dropwort (*Spiraea Filipendula*) through April and May, and the cocoons are clustered together, being attached to the stems of grasses, and rather closely woven, though the tenant only remains therein a short time. The larva feeds in the autumn, and then hibernates. Though, in the majority of the specimens of the moth which we see there are six distinct crimson spots on the deep green ground

colour, individuals turn up sometimes which have all the spots confluent, forming a sort of band across the wings.—
J. R. S. C.

FLOWERS FOR OUR BORDERS.—No. 13.

MARTYNIA FRAGRANS.—SWEET-SCENTED MARTYNI.

This handsome annual, though no longer a novelty, or, perhaps, it might be said, because no longer a novelty, is apparently less cultivated than it deserves to be. Though open to the charge of being somewhat coarse in foliage and habit, its showy crimson-purple flowers are so freely produced through the later summer months that this defect may very well be tolerated. When first introduced the *Martynia fragrans* was treated as a tender annual, but experience has long since proved that it succeeds well in the open ground, and may, if desired, even be sown in the border when a frame is not at hand.

When treated as a half-hardy plant it often happens that owing to the thickness of the integument, the seed remains some time dormant. To remedy this, the seed may be ad-

Martynia fragrans.

vantageously steeped in warm water for an hour or two, which will so soften the woody testa that a portion of it may be readily cut away with a sharp penknife, care being taken to avoid injuring the cotyledons. The seeds are best sown singly in small pots filled with the light compost usually employed for the seeds of half-hardy plants, and when above ground the plants should on no account be forced in a strong heat, but be allowed abundance of air in suitable weather that they may become robust and dwarf in habit, and if specimens of the maximum size are desired, the seedlings should be shifted into larger pots as these become filled with roots. If the seeds are not sown singly, the young plants should be separately potted as soon as large enough to handle without injury.

Before finally planting-out, the plants should be gradually inured to the temperature of the external atmosphere in a cold frame, or where this convenience is not at hand, the plants may be covered with a hand-light after being transferred to the borders, this protection being gradually withdrawn.

The *Martynia* delights in a light rich soil and a free supply of water. Being somewhat succulent in habit its stem requires support, and as, from the large size of its foliage, it is rather liable to injury from high winds, a partially sheltered situation should be afforded it.

Those amateurs who may be unable or indisposed to give attention to the foregoing details, may be glad to learn that almost equally satisfactory results may be attained by sowing the seed where the plants are intended to bloom about the end of April. The preliminary soaking may be tried, but the skin should not be pared off, the lower temperature of the soil rendering this peeling more hazardous than when the seed is

sown in a hotbed. The vegetation of the seed in the open ground may be somewhat slower than in a frame, but when once the seedlings have fairly struck root into the soil, their progress will be almost as rapid as in the case of those raised under more artificial conditions, whilst their habit will be sturdier and more robust.

The flowers of this plant are, as their name implies, remarkable for their vanilla-like fragrance, and well deserve a passing notice. Each is furnished with two bracts or leafy appendages, situated immediately beneath the true calyx, the latter being divided at its border into five nearly equal segments. Within the inflated throat of the corolla will be found four stamens in two pairs, of which one is longer than the other, and also the rudiment of a fifth stamen; the two cells of each anther are united by a connection, which is prolonged beyond the cells, and terminated by a gland-like body. The flower is followed by a singular woody fruit or seed-vessel, which is prolonged into a horn-like beak. This, as the fruit ripens, splits into two portions, which has, perhaps, given rise to the statement that the capsules of this genus are two-horned. These horns are said to cause great annoyance to travellers in Mexico by catching hold of their clothes. They have also given rise to the popular name of Cornet, Cornes du Diable, Triomphe d'Elephant, by which these plants are known in French gardens. The young seed-vessels gathered while quite soft and tender are employed in France and some other countries for pickling in vinegar.

Besides the *M. fragrans*, which it should be stated occurs in some catalogues under the name of *formosa*, *M. lutea* with dingy yellow flowers, and *M. proboscidea*, pale purple-spotted, are sometimes cultivated, but are less desirable. The plant formerly known as *M. cranioalaria* is now termed *Cranioalaria annua*.

The genus *Martynia* was so named by Willdenow, in honour of John Martyn, Professor of Botany at the University of Cambridge, and author of several botanical works, who died in 1768. The species now under consideration is a native of Mexico, whence it was sent in 1840 to Miss Harvey, of Hayle, in Cornwall, by whom it was first raised.—W. THOMSON, Ipswich.

IMPLEMENTS, STRUCTURES, AND APPLIANCES

AT THE ROYAL HORTICULTURAL SOCIETY'S BATH SHOW.

In the last issue of your Journal, page 77, you say, "the medal boiler of last year was not exhibited." This is incorrect. At Stand No. 7 we exhibited six gold-medal boilers, some very large sizes, and fine specimens of workmanship, and which were inspected by scores of the leading horticulturists, hundreds of gardeners, and others, who came again and again, bringing their friends to look at them, who acknowledged that ours was "the show of boilers upon the ground."

We beg to say that the boilers exhibited, with many others, are sold, that we have orders for more in hand, and no doubt you will find next year this boiler will again stand, as it did at Birmingham and Bath, pre-eminent.—THE THAMES BANK IRON COMPANY, Upper Ground Street, London, S.E.

[We insert the enclosed, and regret we had overlooked the boilers, not having been exhibited by the same firm as competed last year, but by the Thames Bank Company, successors to Lynch White. If our readers should take the trouble to refer to our notes of last year it will be found we reported very favourably of these boilers, and we regret that we inadvertently missed them.—EDS.]

A ROSE CURED OF MILDEW.—I have to thank you for saving a *Marcchal Niel* Rose tree which was dying apparently from mildew. I tried first soot and then soft soap as recommended in one of your back numbers, after utterly failing with sulphur, and it is now a beautiful, healthy-looking tree.—S. A. E.

NOTES AND GLEANINGS.

We have received from Mr. Culverwell, of Thorpe Parrow, some of his *PELOPIC MARROW PEA*. It is one of the largest Peas we have ever seen at table, and though not so sweet as the *Ne Plus Ultra*, is a fine-flavoured Pea, and will suit the taste of those to whom *Ne Plus Ultra* is objectionable.

— In a description of the vegetation of the bottom lands, Mr. Robert Ridgway gives numerous particulars respecting the DIMENSIONS AND HABIT OF THE PREVALENT FOREST TREES OF THE LOWER WABASH. These number nearly one hundred

species, of which about seventy exceed 40 feet in height, about fifty exceed 70 feet, and nearly thirty are known to reach or exceed the height of 100 feet. The ordinary height reached by the forest mass is about 130 feet; and above this general level occasional trees rise to an altitude of 200 feet, or perhaps more. The largest of these trees is the Sycamore (*Platanus occidentalis*), attaining sometimes a diameter of 20 feet, and a height of 200, with the lowest branches 90 or 100 feet above the ground. The Tulip Tree (*Liriodendron tulipiferum*) is the second in size, being found 180 feet high, and 37 feet in circumference. A stick from this tree is mentioned as measuring 74 feet in length, being straight and symmetrical, and tapering from 23 feet to 18 in circumference. The tallest Cottonwoods (*Populus monilifera*) are equally high. The Pecan (*Carya oliviformis*) reaches 175 feet in height, with a clean straight trunk of 60 to 90 feet. Among the Oaks the most stately and symmetrical is the Spanish Oak (*Quercus coccinea*, var.), frequently 150 feet high, and 15 to 20 feet around; while the most massive is the Burr Oak (*Q. macrocarpa*), of equal height and rather larger diameter. The White Ash follows, nearly 150 feet high; the Black Walnut, 125 feet high, and over 20 feet in circumference; and the White Oak, 140 feet high, over 17 in circuit. The tallest tree in proportion to its girth is the Sweet Gum, exceeding an altitude of 160 feet, with a clear shaft of over 100 feet, and a maximum circumference of 17 or 18 feet. The Honey Locust attains a height of 120 feet, the Red Maple exceeds 100, and even a *Sassafras* has been measured with a height of 95 feet.

— Mr. J. C. STEVENS has recently been very active in disposing of collections of *ORCHIDS* at his rooms in King Street, Covent Garden. On the 17th of last month upwards of 600 lots from Oceana and the surrounding districts came under his hammer, realising about £660. *Odontoglossum triumphans* in lots of a dozen brought from £2 to £2 10s., and the beautiful *Masdevallia Harryana* from £2 to £3 10s. a-piece. A further portion of Mr. Wilson Saunders' collection was sold on the 15th of July, comprising many scarce plants. *Hechtia argentea* brought £1, and *Geonomas*, *Euterpes*, *Dæmonorops* and other Palms from £2 to £3 5s. On the 23rd, again, there was another sale, in this case of the Orchids belonging to R. Barnett, Esq., of Blackheath Park, at which a fine plant of *Cattleya Trianai Alicia* was knocked down at £7 10s.

— The *Pull Mall Gazette* states that a curious practice has of late been adopted by fruiterers which cannot be called adulteration, but which is very near akin to it. Persons on buying West Indian Pine Apples at fruiterers' shops are asked whether they wish to purchase "heads" to the fruit. In other words, West Indian Pine Apples are dressed for dessert at a small cost as British hothouse Pines by the ingenious plan of inserting in the summit of the fruit a crown of leaves belonging to the latter, and thus guests are deceived into the notion that the Pine Apple which graces the table was grown in the hothouse of their host, who probably never had a hothouse, and knows nothing about the cultivation of Pines. A West Indian Pine Apple has no more right to wear a British crown than an Apple or a Peach has to employ rouge for the purpose of concealing its pallor or heightening its bloom. Although we never saw this toileting of fruit, yet we have seen the blue-bag employed to restore the bloom to Black Hamburg Grapes.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE occurrence of genial weather with showers will have brought the recently trenched ground to good condition for planting the latest crops of *Broccoli*, *Cauliflowers*, and *Winter Greens*, which should be prosecuted without delay; those of the same vegetables now advancing should have the earth frequently stirred with a fork. The too-common practice of drawing the earth up to the stems with a draw-hoe is so much time wasted; for what with the superficial work which such a hoe makes, and the trampling back and forwards, the centres between the ridges become as hard as gravel walks, forming ditches in wet weather and immense cracks and fissures in drought, and thus producing those very effects which surface-stirring is intended to obviate. When the crops are such as require the support of earth drawn up to them, the spaces between the ridges of earth should be well and deeply forked up. Make a sowing of *Chervil* for autumn use. The *Cucumbers* intended for house culture through the winter must be shifted into larger pots as those they are in become filled with roots. A portion of the ground where Potatoes have been lifted should be manured and dug, and planted with old English *Coleworts*, *Ragged Jack*, and *Siberian Kale*, all of which are very useful

late in the spring, just before the young Cabbages come in. Make a small sowing of East Ham *Cabbages* for early spring use, and see that a piece of ground is in readiness for the main crop, which must be got in early next week. Continue to transplant *Endive* as circumstances require; another sowing may also be made. Keep a succession of *Lettuces* sown and planted; they will now require a good supply of water to make them eat crisp and fresh. A good space may now be sown with *Flanders Spinach* for autumn and winter use. This is by far the best sort for winter use, although not in general cultivation. The seed is nearly round and smooth, very like the common Round Spinach.

FRUIT GARDEN.

Prepare the borders intended for new plantations of Strawberries by very deep trenching, and afterwards lay on a dressing of half-decomposed manure and fork it in. Old worn-out beds had better be trenched-up and the crop changed. Keep the runners well removed from the permanent beds. Applications of liquid manure and soot will be beneficial at this season. It seems very difficult to keep down the ravages of aphides on fruit trees this season, and stringent remedies will still be necessary or the hopes of another season will be frustrated. Thin-out the shoots of Figs, and keep them well nailed-in. Out-door Grapes are late, and will require every attention in stopping and training the shoots as often as possible, to give them all the benefit of the action of sun and air.

FLOWER GARDEN.

Proceed with the budding of Roses where the bark rises freely, but if it is dry defer the operation until we get more rain. I have lately been over my best Roses, and instead of cutting-out the dead flower-buds, have thinned-out all the weak shoots, only leaving such as will be required at the winter's pruning; the buds on those left will be much stronger in consequence, and I calculate on a fine bloom next season. The half-ripened wood of China, Tea, Bourbon, and Noisette Roses strikes freely at the present time and until the end of September if placed on a gentle bottom heat. Evergreens in the shrubbery which require pruning should now be attended to without delay. Proceed with the clipping of Box edgings; by attending to this at the present time neatness will be secured, and the edgings will maintain their uniformity for a greater number of years. Evergreen hedges which divide this department and encircle its outskirts should undergo the same operation. Advantage should be taken of moist weather to prick out the principal sowing of biennials into nursery beds; allow plenty of room between plant and plant if it is intended to let them remain in the beds till spring. Propagate *Antirrhinums*, *Pentstemons*, *Phloxes*, and other showy herbaceous plants by cuttings; they take root readily covered with hand-glasses under the shade of a north wall. Tulips may now be divested of their superfluous skins, and thoroughly cleaned whenever the florist can spare time. *Dahlia*s should be constantly watched and regularly tied as they advance, as the side shoots are extremely liable to be wrenched off by the wind. Pansy seed may still be sown, and the beds made of rooted cuttings. When the weather is showery plant out Pink pipings.

GREENHOUSE AND CONSERVATORY.

This is trying weather for hard-wooded pot plants, and those who do not pay strict attention to them now will probably not find it worth their while a few weeks hence. Above all things, see that they are not suffering from want of water, especially on that side of the pot which the sun's rays impinge upon, and keep a sharp look-out for insects. The red spider will soon play havoc among your *Chorozemas* if not closely watched, as will also the mildew on such plants as *C. Henchmanni* and *angustifolium*. To guard against both these pests and many others, it is a good plan to lay the plants on their sides, and, after giving them a thorough good washing with a syringe and clean water, to dust the under sides of the leaves with sulphur. This after remaining on a week or ten days may be washed-off again, and will generally clean the plants for the season. A good washing will also be beneficial to most pot plants at the present time. I do not mean a mere sprinkling, but a thorough washing by using several gallons of water to each plant, and washing each separately. On hot dry days give the plants in the evening a sprinkling, and also the ground on which they are standing. *Pin-lea spectabilis* and other kinds which have done blooming must have the branches liberally shortened-in and be set in a cool shady place to break, as must also the different kinds of *Polygalas*. *Aotus gracillima* must be cut down close to the pot, and *Leschenaultias* which are getting shabby must have all the flowers and flower-buds removed, and be placed in a cool place to start again. Take care they are clear of insects, and sprinkle them once or twice a-day in warm weather. Use no time in bringing the potting of specimens to a close, and be careful with the plants afterwards until they begin to show signs of growth. The young plants in pits must be exposed to the dews every evening, but beware of heavy rains. Stop over-luxuriant growth, recollecting that round, compact, sturdy growth is desirable at the present time, and that naked plants are at a discount.

STOVE.

Stove plants which flower late in the autumn, and especially those that may be taken to the conservatory to bloom, should now, or very soon, be in their flowering pots. The *Eranthemum pulchellum*, *Eschynanthus grandiflorus*, several *Justicias*, *Aphelandra cristata*, *Poinsettia pulcherrima*, and many more of that character belong to this class. Another very essential point to be observed with stove plants in general, which are removed to the conservatory when in flower, is to have the compost lighter for them and not give them more pot room than will just keep them healthy with the assistance of liquid manure, as plants of this nature suffer very much in a cool conservatory late in the season if they are growing in very rich composts and in large pots, whereas in a stove that would be the right way to make them flourish.

PITS AND FRAMES.

Gather and sow the seed of *Pelargoniums* as soon as ripe, as also of *Calceolarias* and other similar plants. Pot-off cuttings that are rooted, and continue to put in such as are wanted.—
W. KEANE.

DOINGS OF THE LAST WEEK.

The continued drought is telling upon our plants and flower beds, and upon the crops in the kitchen garden. We envy those gardeners who, when they come round and remark on the brown appearance of our parched lawn, tell us that they have only to turn on the water, and the hose and spreader throws it all over their garden. We have to draw some of ours in handcarts nearly 200 yards. The cost of labour is now becoming serious, and is likely to become more so in the future; therefore any appliance that will lessen labour and do the work as effectually as it can be done by human power ought to be carefully considered. Where water can be obtained at high pressure from waterworks, the cost of laying pipes all over the garden is as nothing compared to the labour in drawing water a distance and applying it by hand. If the above convenience does not exist, probably the next best scheme would be to pump the water up into a tank, raised as high as possible, and lay pipes from this. On the other hand, as we stated last week, much may be done by trenching the ground in winter and applying manure in a judicious manner. We are truly sorry to read that the Potato disease has appeared in Sussex. Large quantities of Potatoes are grown about here for the London market, but we have not seen any disease, nor have we heard of its appearance in our own immediate neighbourhood. Let us hope the present fine weather will keep it away.

FRUIT AND KITCHEN GARDEN.

We are preparing the ground for *Strawberry* planting according to our usual method. We like to have the trenching done a few weeks previous to putting out the plants, and it is also best to plant out after the ground has been moistened with rain. The plants are now all ready in small pots. As our ground is light we used to mix with it some clayey loam, but as that cannot readily be obtained we will only dig out a hole for each plant sufficiently large to hold a shovelful of loam in which to place the plant. As a precaution against red spider each plant is dipped in a pail of water in which half a pound of soft soap and 1 ozs. of tobacco have been dissolved. The pot in which the plant is growing is taken in the hand and inverted, all the leaves are plunged in the water, the pot is then laid on its side so that the water may drain off the leaves and not soak into the soil in the pot. In planting do not omit to leave a slight depression round each plant, so that if the weather continue dry abundant supplies of water may be given.

The latest crops of Peas are looking well; the ground had not been cropped, so that it was in good condition for the seeds to go in. The rows have been hoed, earthed-up, and the sticks placed to them. The earliest Onions have been harvested and are very fine. We sow in September and plant them out in rows about the end of February or beginning of March. Onions treated in this way are always free from the Onion grub. We sow James' Keeping in spring for keeping latest; these are also very fine. As much cannot be said of the Carrots, which are very much infested with the worm.

I ought also to say that the *Doyenné d'Été* Pear is now in, also Red Astrachan and Early Red Margaret Apple, while Rivers' Early Prolific Plum is loaded with its rich purple fruit, which can be gathered in handfuls.

FRUIT AND FORCING HOUSES.

The greater proportion of the *Pines* in the fruiting house have been cut, which necessitated a re-arrangement of plants in all the houses. The few plants showing fruit in different stages of development were placed tolerably thickly together in one end of the bed; this arrangement allowed the most forward of the succession plants to be placed not quite so thickly at the other end of the bed. The second house was re-arranged in the same way, the bed being turned over and some cocoa-nut fibre refuse added. We also potted all the suckers that we require, and plunged them in bottom heat several degrees higher than the

beds in the houses where the active roots were round the outside of the pots.

Vinerias.—In the early houses the few scorching hot days we have had have told upon the foliage, and are causing much of it to drop off. Abundant supplies of air are necessary night and day. The wood seems hard and well ripened, but one is often deceived in this. The season has not been very favourable for well maturing the wood in the earliest houses. As to the late houses note what was said about Lady Downe's last week in regard to scalding; we hear of some persons who have had their fruit of this sort much damaged by not giving air enough during the hot scorching weather of last week. Throw all ventilators and doors open during hot sunshine; after the berries begin to colour the danger is over. We are always more troubled with red spider in the late houses. As we do not fire much the pipes are not often heated, and during summer it is injurious to shut the houses quite close and to heat the pipes sufficiently to cause the sulphur fumes to take effect. The Grapes seem to colour well; the berries and bunches are also large. We leave the ventilators open both front and back at night.

ORCHARD HOUSE.

The Early York Peach is now in. Early Grosse Mignonne and Rivers' Early York are swelling rapidly and will come in soon after it. We have the house pretty free from red spider, so that syringing may be discontinued in a few days. If any trace of this pest should be on the trees it will spread with great rapidity, and in a fortnight the leaves will be destroyed. More caution is requisite as regards watering when the trees are ripening-off their fruit. Too much water will cause the fruit to be watery and wanting in flavour, while too little water will also cause the fruit to be inferior. Let each tree (I allude, of course, to pot trees), be moderately dry before it is watered, but not so much so as to cause the points of the young growing shoots to flag. The house must also have the ventilators both at front and back a little open all night.

CONSERVATORY AND PLANT HOUSES.

In the stove a general re-potting of the plants, Ferns, &c., has taken place; the plants have been re-arranged and allowed space to develop themselves. Nothing is so injurious to plants as overcrowding them, especially towards autumn, when air and light are necessary more than at any other time to perfect the growths. Once every week we look over the conservatory, remove all plants that have gone out of flower and have a seedy appearance, and replace with fresh specimens which have been growing either out of doors or have been brought forward in pits and frames. We find the ordinary Zonal Pelargoniums, both single and double, of great value at this time of the year for decorative purposes.—J. DOUGLAS.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

NOTICE TO QUIT (A Reader).—If you were paid your wages weekly you cannot demand more than a week's notice.

ROSE-BUDS DROPPING (J. S.).—Your question was answered at page 86.

LILIUMS (Mrs. H.).—If you advertise your wants you will probably find some one willing to exchange, but we cannot undertake to negotiate such matters.

PEA (J. B.).—The specimens were in such a state when they arrived that it was impossible to form any opinion.

SEEDLING PANSY (Mulligan and Kerr).—The Pansy, as far as we could judge, is a good variety, but not superior to others in the same style already in commerce.

USE OF CUCUMBER HOUSE (A Constant Reader).—We do not think you could do better than have Cucumbers on both sides of the house. Tomatoes would, however, succeed, but they would not pay nearly so well as the Cucumbers.

POT CULTURE OF CAZAR VIOLET (A Subscriber).—Your plants are probably old and have been some time in pots. We like them best in pots, from rooted runners or offsets planted singly in April in good rich soil in the garden on an east or west border, or other place shaded from powerful sun. Ours are on a north border a foot apart every way. The soil is kept stirred between the rows, and all runners as well as all weeds are removed. In September the plants are taken up with balls, potted in 6-inch pots, placed in a cold frame on ashes, shaded from bright sun until they are again established, then light and air are freely admitted. From the frame they may be drafted into the greenhouse as required. We should plunge your plants in the open ground, and keep off all runners. In September we would have them taken up and re-potted without disturbing the ball much, placing them in a cold frame until re-established. In October they may be placed on shelves in the greenhouse, where they will bloom well during the winter.

STORING SEED POTATOES—TRANSPLANTING ASPARAGUS (D. F. J. K.).—It is a good plan to place the tubers thinly on a floor or on shelves, but not in layers with straw between them, as those in the centre will be liable to sprout too soon. They are best stored on lattice-shelves with the useful protection from frost. The thinner they are laid on the shelves the better. The nearer the temperature is kept to 39° the less they will be liable to suffer from premature growth. The best time to transplant Asparagus plants into old beds is in spring, just before or when they are beginning to grow. The Carrots you have transplanted may form short stubby roots, they seldom form handsome roots. They need no particular treatment, except to be watered if the weather be dry. Consult a farmer in your locality as to the latest time of sowing Rape for spring feeding. The best remedy for the rabbits would

be to trap them, or place snares in their runs; poisoning would not be justifiable.

IVY ON A WALL (A. B.).—No doubt Ivy harbours insects, and no doubt also insects have the inconvenient habit of eating fruit, we should therefore advise you not to plant the back of your fruit wall with Ivy. Why not plant Currants or Morello Cherries against it? Collect all the liquid which drains from your hotbeds and manure heaps. It is the best dressing you can give to green crops.

VIOLETS IN A GREENHOUSE (—).—You may plant either the Neapolitan—the Czar, or the Victoria Regina Violet on the Peach border; a few of each would give you a variety.

DESTROYING GOOSEBERRY CATERPILLAR (G. H. B.).—We extract the following from the "Gardener's Year-Book," page 70:—"The most simple, least expensive, and most certain method of exterminating this pest is to cover the surface of the ground early in spring all round the Gooseberry bushes 2 or 3 inches thick with fresh tan from the tanyard, the same material as is used for bark beds. Let it remain till the autumn or winter following, and then dig it in. In November or December remove the earth from round the stem of each tree for about the space of 18 inches, and as deep as the roots will permit. Expose the roots to the weather for three or four weeks, then fill-in with manure or fresh earth."

TOMATOES NOT FRUITING (Idem).—The plants must need water. In no other way can we account for the fruit not swelling. We should discontinue the pinching, and keep them well watered in dry weather. It is likely you have by stopping caused the production of a multitude of shoots, and that they are consequently crowded. Thin them out so as to admit light and air. You may yet have a crop, which will ripen in autumn, or the plants may be cut before frost and hung up in ainery to ripen the fruit.

STOVE PLANTS FOR WINTER AND SPRING FLOWERING (S. L.).—*Centropogon Lycopodium*, *Anthurium Scherzerianum*, *Apheleandra nanantia* Roeblii, *Burchellia capensis*, *Clerodendron Balfourianum*, *Dalecampa Roeziana* rosea, *Eranthemum pulchellum*, *Euphorbia pucinissiflora*, *Inantophyllum miniatum*, *Monochatum cuscutifolium*, *Plumbago coccinea* superba, and *Thyrasactium rutifolium*. Fine subjects for winter-flowering are *Begonia fuchsoides*, *Ingramia*, *insignis*, *maucata*, *nitida*, and *hybrida multiflora*.

TRICOLOR PELARGONIUM LEAVES COLOURING (J. H. B.).—Keep the plants in a cold pit or frame, and near the glass, but not touching it, and shade from bright sun during the hottest part of the day, say from 9 A.M. to 3 or 4 P.M. Water moderately, and not overhead, admitting air freely. They will improve in colour in autumn.

TALL YELLOW AND WHITE-FLOWERING PERENNIALS (Mrs. C.).—*Ademone japonica* Honorine Jobert (white), 3 feet; *Lathyrus latifolius* albus, 6 feet; *Achillea moschata*, 2 feet; *Aconitum album*, 4 feet; *Aster multiflorus*, 3 feet; *Aster Tradescantii*, 3 feet; *Bocconia cordata*, 5 feet; *Leptandra virginica*, 5 feet; *Lupinus albus*, 3 feet; *Lychnis dioica alba-plena*, 3 feet; *Monarda alba*, 3 feet; *Polygonum cuspidatum*, 6 feet; *Pirrea Aruncus*, 4 feet; *S. barbata*, 4 feet; *S. Humboldtii*, 4 feet; all the above have white flowers. Yellow-flowered plants are—*Centrocraipa grandiflora* and *C. triloba*, 3 feet; *Cephalaria tatarica*, 5 feet; *Helianthus californicus*, *H. multiflorus* flore-pleno, 3 feet; *H. orgyalis*, 6 feet; *Lysimachia mexicana*, *Emothera grandiflora*, *Polygonum complexum*, 3 feet; *Rudbeckia columnaris*, *R. fulgida*, *K. Neumannii*, 4 feet; *Thalictrum discolor*, 4 feet; and *T. squarrosa*, 3 feet.

VARIOUS QUESTIONS (B. K. L.).—The old Gooseberries are not worth transplanting. Plant new ones in November, and they may be within 6 feet of the pyramid Apples. Plant the Raspberries 4 feet apart. You may move every alternate plant of Strawberries any time this month. It is quite possible your *Lagereria rosea* does not like twining on the cold iron rod. Substitute wood, or a cord, or wire. Sow the seed of *Sida vitifolia* in March in gentle heat. Thin Asparagus plants to 1 foot apart. Do this, and fill up blanks, in the end of March. Salt will benefit seedlings. *Chrysanthemums* would bloom better in 9-inch than 6-inch pots. It is not too late to re-pot.

UNHEALTHY VINE (Good Templar).—You have loaded your young Vines too much, and they are suffering from diminished vigour. You must crop them lighter, and encourage this season as much as you possibly can a development of the laterals. Do not pinch them too closely, and allow the leading shoot to grow as long as it will. See that your Vine border is well drained.

THE YEW POISONOUS (A. S. T.).—All the evidence on the subject of the Yew being poisonous to cattle, horses, and deer, leads to the conclusion that when eaten in its fresh state it is harmless, but when withered, or partially so, it is poisonous. The clippings of Yew hedges, for instance, if laid within the reach of these animals and eaten by them have invariably caused death; but it is known that when they browse upon the fresh shoots in parks no such result occurs.

CORDON-TRAINED TREES (E. J.).—You are not definite enough in your explanation. If your single cordons are on a wall they should be planted 18 inches apart, and trained at an angle of 45°. You should now cut all the young wood back to two or three leaves. If they are planted in the open garden let them grow upright. We would plant at least 3 feet apart, and allow the side shoots to grow out more. There is no advantage, but the contrary, in cutting-in too closely.

STRAWBERRY CULTURE (H.).—Strawberry beds last longest in perfection in medium loam, and the shortest time in light sandy soils. Our soil being very light we had it most advantageous to plant a new bed annually. In any soil we would not allow a bed to stand longer than three or four years. If the earliest are layered, as soon as they are ready, in small pots, and the plants put out early in August, they will bear a full crop the following year. The ground should be trenched 2 feet deep and highly manured.

HEATING LEAN-TO HOUSE (R. T. W.).—Seventy feet of 3-inch pipe would keep out the frost in ordinary winters, but to be sure we would put in four rows of 3-inch, or three rows of 4-inch pipes, which last would be preferable.

DESTROYING WOODLICE (A Weekly Reader).—We know of no better plan than to place some damp moss round the sides of the bed, and especially against the walls, and on this pour boiling water some time the following morning. The moss—or hay, which will answer almost as well—may be removed, and immersed in boiling water; this, repeated a few times, will clear the house. The hot water will destroy the Mushrooms with which it may come in contact, but as it need not be allowed to wet more than an inch or two from the wall, there can be no great loss of Mushrooms from the application.

QUICK-GROWING SHRUB FOR PROTECTION NEAR THE SEA (Northern).—The quickest-growing and best of all for affording shelter is the Elder (*Sambucus nigra*). It should be planted 2 feet apart, and as a double row 1 foot

from the other, quincunx fashion. The richer the soil the better they will grow. Subjects of taller growth are the Sycamore, which grows quickly, and stands the sun breezes well, also the Norway Maple, both being deciduous trees. The Austrian Pine and Corsican Pine are evergreen trees, and good for shelter. They are of rapid growth, and stand well.

BEDDING GERANIUMS WITH ORNAMENTAL FOLIAGE (F. L.).—*Golden Trocifers*: Louisa Smith and Victoria Regina. *Silver Trocifers*: Mabel Morris and Prince Silverwings. *Golden Bronze*: The Moor and Harold. Golden Banner is a self-golden-leaved kind without a green-disc or any trace of zone. When the flowers are removed it is probably the best golden-leaved bedding plant known. Yellow Boy is an excellent yellow-leaved variety.

POT POTTER (B. rthm).—If you refer to page 56 of our present volume you will find a receipt.

GLAZING A PEACH HOUSE (Subscriber).—We should prefer transparent glass.

REMOVING EVERGREENS (Sutton Coldfield). You can if you wish remove the Hollies from the hedge, and the best time to do it is in May or June. Cut round the roots now, and move them in the first week of next June.

WEEDS IN MANURE (F. Mason).—If the manure is well fermented there is every probability that the bulbs of the wild garlic and the seeds of Dock will be destroyed. We cannot suggest any other remedy.

INSECTS ON PEAR LEAVES (H. P. Stroud).—It is the Slimy Grab (*Scandria aphidis*). (L. J. K.).—If you will send us the insect we will name it, and a remedy, if such exists.

MEALY BUG ON STEPHANOTIS (H. W.).—Cutting the plant back may be deferred a month, or until you can have it and the roof thoroughly cleaned. In the meantime syringe forcibly with water. In cutting-back and thinning-out, leave as much of the young healthy growth as you can, and clean the plant twice or thrice before tying it up to the roof. It is the most difficult of all insects to get rid of when it obtains a hold.

GNAWED RHODODENDRON AND LAUREL LEAVES (H. D. Hawkhurst).—We cannot inform you what insect has gnawed the leaves of these plants, indeed we much question whether the mischief is caused by insects. It may be by snails, or even by the action of rain and sun. The trees should be carefully examined after dark.—I. O. W.

NAMES OF FRUITS (Hillman Thompson).—Both No. 1 and No. 2 are the Early Red Margaret or Red Jeannette. The White Jeannette is quite a distinct sort. We have never met with the name Katherine before, and are obliged to you for the information.

NAMES OF PLANTS (J. B.).—*Ampelopsis Vitellii*. (H. H.).—1, *Eutoca patuliflora*; 2, *Alkanna species*. (T. S.).—*Arrhenatherum avenaceum*. (T. W. Walford); 1, *Erythraea Centaureia*; 2, *Scabiosa succisa*. (*Major T. Mason*).—1, *Emothera Fraseri*; 2, *Potentilla*; 3, *Alyssum saxatile*; 5, *Gonista tinctoria*. (B. W.).—*Begonia boliviensis*.

POULTRY, BEE, AND PIGEON CHRONICLE.

BEDFORD POULTRY SHOW.

This was held on July 31st, in conjunction with the Bedfordshire Agricultural Society's Show. It proved a great success, although the morning was anything but promising. Just as the poultry Judge commenced his duties the rain came down in torrents, and poured through some parts of the large tent like a sieve, more especially so just over the Hamburgs, which misfortune, coupled with their inferiority, made them rather objects of pity than otherwise; but by the time the Exhibition opened to the public the sun shone forth in his full radiance, and by two o'clock a more beautiful day could not be desired. We could but observe that even with the great attractions of the Coldstream Guards' band, the flower show, the stock, and the horse ring, the poultry tent was the most crowded of all. It contained many good specimens in the various classes, which were shown in Mr. Billett's pens, and we noticed the zeal and energy of the poultry sub-committee, who, with the assistance of Mr. Billett, took every possible care of the specimens committed to their charge, and had the whole repacked and delivered to the Railway Company the same evening.

DORRINGS.—1 and 2, Rev. E. Bartram, Berkhamstead. *Cock*.—1, E. Southwood, Fakenham.

COCHINS.—1, R. S. Woodgate, Pembury. 2, Master Eivon, Fulham. *he*, T. Alberton, Leighton Buzzard; R. B. Stafford; J. Robinson, Wislhamstead. *c*, J. Watts, Bedford. *Cock*.—1, F. Fryor.

GAME.—*Black-breasted Red*.—1, A. C. Swain, Radcliffe. 2, R. B. Stafford. *he*, F. Simpkins, Luton; R. Hall, Cambridge. *Any other variety*.—1, R. Hall (Duckwing). 2, J. Mason, St. John's, Worcester (Duckwing). *Cock*.—1, H. Lotan, Oundle. *he*, R. Hall.

SPEARS.—1, W. R. Bull, Newport Pagnell. 2, Master Eivon. *Cock*.—1, W. R. Bull.

BRAMA POUTRA.—1, F. Fryor. 2, M. Leno, Markyate Street. *he*, Cross and Mansfield, Cambridge; J. Holmes, Whitecotes, Chest-rfield. *c*, A. S. Thornton, Kempston Grange. *Cock*.—1, H. Clarke, Bedford.

GAME BANTAMS.—*Black-breasted Red*.—1, T. W. Anns, Clapham. 2, E. Southwood. *Any variety*.—1, Withfield. 2, Master P. M. Payne (Buff).

BANTAMS, NOT GAME.—1 and 2, M. Leno. *Cock*.—1, M. Leno.

ANY OTHER VARIETY.—1, P. J. Madden, Bugthwaite. *he*, H. Feast, Swansea. French. *c*, Master P. M. Payne (Maple-eyed Silk Fowls).

FARMYARD.—1, T. Alberton, Heath and Beach, Leighton Buzzard (in County only). 2, R. B. Stafford. 3, M. Hebban, Bromham Grange.

DUCKS.—*Aylesbury*.—1, T. Sear, Tangwick. 2, G. Kirby, Ailsey Siding. *c*, A. Markwell, Bedford, Ely. *Rouen*. 1, E. Bartram. *Any variety*.—1 and *he*, M. Leno (Kasarka and Whistling). 2, J. J. Madden (Black East Indian).

GUINEA FOWLS.—1, O. E. Cresswell, Early Wood, Bagshot. 2, M. Leno.

GIFFER.—1, Miss Roe, Crescent, Bedford. 2, M. S. Thomas, Bletsoe. *he*, A. Markwell, Bedford, Ely.

FIGEONS.

CARRIERS.—1, T. Chambers, jun., Northampton. 2, S. Weatherhead, Luton. *he*, J. Atkins, Bedford. 1, H. Palmer, Bedford.

PUTTERS.—1, R. Kingston, jun., Chatteris. 2, L. Watkin, Northampton. *c*, J. Atkins.

JACOBINS.—1, H. Yardley. 2, T. W. Swallow, Northampton.

ANTWERPS.—1, W. E. Bull. 2, R. Hall. *he*, A. R. Burrell, Cambridge; J. Atkins; H.

FANTAILS.—1, J. F. Loversidge, Newark. 2, O. E. Cresswell. *c*, J. Atkins Miss Moller, Cardington.

TRUMPETERS.—1, C. Norman, Westfield, Ipswich. 2, H. Yardley. *Any Variety*.—1, C. Bryant, Bedford (Blue Owls). 2, C. G. Hitchcock, Oxford (Black Macpie). *he*, J. Atkins; C. Bryant (Archangel); L. Watkin, Northampton; H. Yardley. *c*, C. Norman (Barbs); Master J. P. Day, Bedford (Mottled Tamblers).

RABBITS.—*Long-ear*.—1, F. Banks. 2 and *c*, F. Purser and C. Bryant, Bedford. *he*, T. Smith, Bedford. *Angora*.—1, F. J. Smith. 2, S. Ball, Bradford. *he*, W. G. Hancock, Northampton; F. J. Smith. *c*, S. Youl, Northampton. *Himalayan*.—1, S. Ball, Bradford. 2, A. Hudson, Hill. *he*, F. Sibbage, Northampton. *Silver Grey*.—1, S. Ball. 2, H. W. Anns. *he*, S. Russell, Northampton. *c*, F. Purser and C. Bryant. *Selling Class*.—1, T. Garner, Kimschoupe. 2, F. Purser and C. Bryant (Sandy and White). *he*, T. Smith (Grey and White).

JUDGE.—Mr. W. B. Jeffries, Ipswich.

DEVON AND EXETER POULTRY SHOW.

This was held in the Victoria Hall, Exeter, on July 31st and August 1st. The following are the awards:—

POULTRY CUP.—Equal, H. Feast, Rev. G. S. Cruwys.

BRAHMS.—*Dark*.—1, T. H. Waterman, Anderton, Devonport. 2, E. Enzor, Bristol. 3, J. Watts, King's Heath, Birmingham. *c*, T. H. Williams, Brecon, South Wales; E. Enzor. *Light*.—1, T. A. Dean, Mardon, Hereford. 2, Rev. N. J. Ridley, Newbury. 3, J. Turner, Tiverton, Bath. *he*, N. Heath, Totnes. *c*, J. Bloodworth, Cheltenham; Mrs. H. Popham, Chichester; N. Heath; H. D. France, Bunk, Totnes; J. Turner.

COCHINS.—*Cuckoo or Buff*.—Cup and 1, J. Bloodworth. 2, S. R. Harris, Cusgrave, St. Dav. 3, C. Bloodworth, Rayshill, Cheltenham. *he*, T. A. Dean. *Any other variety*.—1, S. W. Probert, Lostwithiel. 2, J. Turner. 3, Rev. F. T. Hillyard, Oakford, Tiverton. *he*, R. W. Beachy, Fluher, Kimschoupe.

DORRINGS.—1, T. C. Burrell, Micheldever. 2, J. Robinson, Garstang. 3, H. Feast, Swansea.

GAME.—*Black Red*.—Cup and 2, Rev. G. S. Cruwys, Tiverton. 3, Coon and Bros, St. Austell. *he*, T. Coon, Barnstaple. *Any other variety*.—1, H. Browne, St. Austell. 2 and 3, Rev. G. S. Cruwys.

HAMBURGS.—*Golden pencilled*.—1, C. Bloodworth. 2, H. Moore, Weston-super-Mare. 3, G. Lias, Par Station. *c*, T. Edmunds, Totnes; H. Moore; H. Denham, Exeter. *silver-pencilled*.—1, J. Robinson. 2 and 3, Withfield.

HAMELAGUS.—*Gold-winged*.—1, H. Feast. 2, J. Robinson. 3, J. Davies, Harborne, Birmingham. *he*, Mrs. J. Pattison, Dorechester; J. Clark, St. Dav. *Silver-winged*.—1 and Cup, Mrs. J. Pattison. 2, J. Robinson. 3, H. Feast.

MORCARTS.—1, W. F. Eyles, Buckfastleigh. 2, J. Croote, Heavitree, Exeter. 3, T. P. Burton, St. Austell. *he*, Miss S. H. Northcott, Uper Nutwell. *c*, H. Feast; W. Blackmore; F. Hayman, St. Siuwell's, Exeter.

POLANDS.—1, S. W. Probert. 2, G. Lias. 3, C. Bloodworth.

FRENCH.—1, H. Feast. 2, M. H. Sturt, Pewsey. 3, Mrs. Troyte, Bampton. *c*, W. H. Coppleson, Bridgend, Lostwithiel.

ANY OTHER VARIETY.—1, S. W. Probert. 2, Rev. N. J. Ridley. 3, O. E. Cresswell, Early Wood, Bagshot. *he*, J. Robinson.

FANTAILS.—*Game*.—1, E. Seaman, H. Hiperton, Trowbridge. 2, E. Farrington, Barbourne. *Black or White Rosecomb*.—1 and *he*, Rev. G. S. Cruwys. 2, J. Watts. *Any other variety*.—1, Rev. G. S. Cruwys. 2, A. Pigott, Bramford Speke, Exeter.

DUCKS.—*Aylesbury*.—1, J. Robinson. 2, S. Vingo, Ponsanooth, Perranar-worthell. 3, H. Feast.

SELLING CLASS.—*Cock*.—1, W. Coombes, Exeter. 2, H. Feast. 3, J. Croote. *c*, Mrs. H. Popham; G. Packham, Whym, Exeter (4). *Hens*.—1, F. J. Echer, Crediton. 2, G. Packham. 3, E. W. Beachy Extra 3, S. W. Probert. *he*, Mrs. H. Popham; G. Packham (2); Viscountess Chetwynd, Exmouth.

PIGEONS.

PIGEON CUP.—H. Yardley.

CARRIERS.—*Cock*.—1, E. Burton. 2, H. Yardley, Birmingham. *he*, R. Fulton, London. *c*, F. Hayman (2). *Hens*.—1, R. Fulton. 2, E. Burton. *he*, E. Burton; R. Fulton; F. Hayman.

PUTTERS.—*Cock*.—1 and 2, R. Fulton. *he*, G. Holloway, jun., Stroud; G. Packham. *c*, H. Yardley. *Hens*.—1 and 2, R. Fulton. *he*, H. Yardley; G. Packham. *c*, G. Holloway, jun.

TRUMPETERS.—1, H. Yardley. 2, J. Croote. *he*, H. Denham; R. Fulton (2); G. Packham. *c*.—Burton, Exeter; J. Broad, Plymouth.

BAMBS.—1, R. Fulton. 2, H. Yardley. *he*, Bullen & Joce, Newport, Barnstaple (3); R. Fulton. *c*, E. Burton (2).

OWLS.—1, Braund & Geary, Bideford. 2, J. L. Smith, Newport, Barnstaple. *he*, R. Fulton. *c*, H. Yardley.

NUSS.—1, H. Yardley. 2, G. Packham.

DRAGONS.—1, G. H. Gregory, Taunton. 2, H. Yardley. *he*, H. Yardley; R. Fulton. *c*, G. Packham; H. Gregory; H. Denham.

TURKISH.—1, G. H. Gregory. 2, H. Yardley. *he*, Braund & Geary. *c*, J. Croote (2).

FANTAILS.—1 and *he*, J. L. Smith. 2, H. Yardley.

ANTWERPS.—1, H. Yardley. 2, A. Damarell. *he*, F. Beck, Exeter. *c*, J. Croote; H. Yardley.

TRUMPETERS.—1, Braund & Geary. 2, R. Fulton. *he*, G. Packham; Bullen and Joce. *c*, H. Denham.

JACOBINS.—1, H. Yardley. 2, R. Fulton. *he*, Braund & Geary.

ANY OTHER VARIETY.—1, H. Yardley. 2, G. Packham. *he*, H. Denham; G. Packham. *c*, H. Yardley; Bullen & Joce; R. Fulton; J. Croote.

SINGLE BIRD, EXCEPT CARRIERS AND PUTTERS.—1, H. Yardley. 2, Hockaday & Fern, St. Austell. *c*, G. H. Gregory; G. Packham; H. Denham; R. Fulton.

SELLING CLASS.—1, R. Douger, jun., Parkstone, Poole. 2 and *he*, G. Packham. *c*, H. Yardley.

JUDGE.—Mr. W. B. Tegetmeier, London.

HASLINGDEN POULTRY SHOW.

This Show was held on July 31st, and, in point of entries was a great success in all departments. It is long since this Society was favoured with so fine a day, the weather having been very wet at its meetings for many years. The pens for poultry were ranged in single tiers along one side of the field, and the birds were well attended to. We would, however, draw attention to the objectionable system of putting straw on the bottom of the pens, which in no way adds to the comfort of the birds, and in all cases serves as an impediment to the progress of those who have the awards to make.

With true agricultural taste the large varieties of poultry were placed at the head of the list, and the specimens in no way dishonoured the patronage, for finer or better-shown *Geese*, *Turkeys*, and *Ducks* it would be difficult to find at any show, the

Emden Geese and Raven Ducks being particularly noteworthy. Adult *Cochins* in the Buff class were in fair feather and condition for the time of year, and the chickens of that variety very promising, but the Partridge, both old and young, were scarcely of equal merit. Of adult *Brahms* there were but two good pens shown, but of young the entries were more numerous, and the pullets mostly forward and good in colour and marking. *Dorkings* were fair in the adult class; and the young, though not forward, were very good in feet, form, and colour. The *French* fowls were mostly *Creve-Coeurs*, and very good in feather and size. *Spanish* were shown singly, and both lots were very good, the size and quality of face in both sexes being a great improvement upon previous years. Mr. Brierley had the *Game* classes all to himself, and the birds that won the prizes were well worthy of their positions. There were two classes for Game, to be shown by exhibitors residing within two miles of Haslingden, and these also contained some good specimens, notably the single hens, which were Brown Red and Pile. Adult Golden-pencilled *Hamburghs* were of very good quality; the chickens, which were more numerous, had many good pens. In Silver-pencilled only the winners were noticeable, but these were really good, and the chickens also good in quality. Of Golden-spangled *Hamburghs* there were some good birds, mostly hens, but the chickens were not nearly so forward as the other varieties. The adult Silver-spangled were in fair bloom and of good quality, and the chickens really good, some of the pullets being grand in marking and colour. The two winning pens were near perfection, and among the chickens were some extremely neat pairs of birds, the colour and style of all being remarkably good. In the Variety class Golden *Polands* were first and Malays second. The local class for Game *Bantam* cocks was tolerably well supported, the first being Pile and the second Black Red. In the open class for cocks the first-prize bird was also an almost perfect Pile, and the second a very good Black Red. There were no good White Bantams, and Blacks won the prizes for those varieties, both birds being very good. The first prize in the Variety class was won by Silver *Sebrights* of perfect ground colour, and the second by very pretty *Pekins*. Both pairs of winners in the class for Game Bantams were Black Red pullets of this year, several other pairs being good, but not in nice feather.

The entries of *Pigeons* were very good, as also the *Rabbits*.

COCHIN-CHINA—*Buff or Cinnamon*.—1, W. A. Taylor, Manchester. 2, T. F. Ansdell, Cowley Mount, St. Helens. *he, W. A. Taylor, W. Harvey, Sheffield. Chickens*.—1, W. Mitchell, Leeds. 2, *he, C. Sidgwick, Kirkstall.*

COCHIN-CHINA—*Any other variety*.—1, A. Bamford, Middleton. 2, W. A. Taylor. *he, W. Hey, Littleborough; W. A. Taylor. Chickens*.—1 and *he, W. A. Taylor. 2, C. Sidgwick.*

BRAMMAS.—1 and 2, T. F. Ansdell, *Chickens*.—1 and 2, J. H. Pickles, Birkdale. *he, H. Beldon, Goffs-wook; W. Whiteley, Clonch, Sheffield. Dorkings*.—1, W. Harvey. 2, T. Stott, Hecley, Rochdale. *he, J. Robinson, Garstang. Chickens*.—1, T. Briden, Earby, Skipton. 2, T. Statter. *he, W. H. King, Rochdale. 3, T. Statter; J. Butterworth, Rochdale.*

FRENCH.—1, J. Robinson. 2, G. W. Hibbert, Gofley, Hyde. *he, J. H. Fielden. SPANISH*—*Black*.—*Cock*.—1, H. Beldon. 2, J. Powell, Bradford. *he, E. Suddall, Haslingden. c. J. F. Sillitoe, Wolverhampton. Hen*.—1, J. Powell. 2, E. Suddall. *he, H. Beldon, Bingley; J. F. Sillitoe (2); E. Suddall.*

GAME.—*Cock*.—1 and 2, C. W. Brierley.

GAME.—*Cock*.—*Within two miles of Haslingden*.—1, F. Walton, Rawten-stall. 2, N. Storey, Haslingden. *Hen*.—1 and 2, E. Suddall, c. J. R. Isherwood.

GAME.—1 and 2, C. W. Brierley.

HAMBURGHS.—*Golden-pencilled*.—1, H. Beldon. 2, J. Robinson. *Chickens*.—1, E. Clayton, Keighley. 2, W. Clayton, Keighley. *he, E. Clayton; G. & J. Duckworth, Church. c. J. Robinson.*

HAMBURGHS.—*Silver-pencilled*.—1, H. Beldon. 2, J. Robinson. *Chickens*.—1, J. Robinson. 2, H. Smith, Keighley. *he, H. Smith; H. Beldon.*

HAMBURGHS.—*Golden-spangled*.—1, G. & J. Duckworth. 2, J. Newton, Silsden. *he, J. Robinson. N. Marley, Denton. Chickens*.—1, N. Marley. 2, J. Hall, Stacksteads. *he, T. Maw, Wolverhampton; J. Newton. N. Marley. 2, J. Hall, Stacksteads.*

HAMBURGHS.—*Silver-spangled*.—1, J. Robinson. 2, H. Beldon. *he, J. Robinson. Chickens*.—1, J. Robinson. 2, J. Robinson. *he, J. Ashworth, Burnley; C. Parsons, Wolverhampton; H. Robinson, Leeds; J. Robinson; T. Smith, Keighley.*

HAMBURGHS.—*Black*.—1, H. Beldon. 2, J. Moore, Bingley. *he, N. Marley; W. A. Taylor. Chickens*.—1, J. Moore. 2, T. Walker. *he, C. Sidgwick; T. W. Hobbes, Rutherford, Leeds; J. Moore; W. A. Taylor.*

ANY OTHER VARIETY.—1, H. Beldon. 2, Rev. A. G. Brooke, Strawfieldine.

SELLING CLASS.—1, Birch & Boulter. 2, A. Bamford, Middleton. *he, H. Beldon; E. Suddall.*

GAME BANTAMS.—*Cock*.—*Within two miles of Haslingden*.—1, Miss A. Walton, Rawtenstall. 2, G. Haworth, Haslingden. *he, T. Green, Sunnyside, Crawshawbooth; A. Burton, Haslingden; J. R. Isherwood.*

GAME BANTAMS.—1, W. B. Entwistle, Westfield, Bradford. 2, G. Hall, Kendal. 3, T. Barker, Burnley; W. F. Entwistle; E. Pickun, Lumb, Newchurch. *Hens*.—1 and 2, W. F. Entwistle. *he, T. Barker; G. Hall, Kendal (2); G. Booth, Haslingden.*

JUDGES.—*Poultry and Rabbits*: Mr. L. Hutton, Pudsey. *Pigeons*: Mr. T. Rule, Durham.

LEICESTER POULTRY SHOW.

This Show took place on July 29th, and the following day. It was held under a very spacious tent on the Leicester Race-course, Messrs. Turner, of Sheffield, supplied the pens. Great attention was paid to the birds, and the Committee, we were glad to find, had numerous entries from the best poultry yards in the country. Following the rule of late, *Dorkings* were not nearly so good classes as might have been fairly expected; and more remarkable still, there were only two entries of *Spanish*

in the adult class, and not a single entry in that for pairs of Spanish pullets, nor, again, in the class for a single cockerel. Having passed the two breeds just named the entries changed, so as to include a large competition of such chickens as have not been seen for a number of years in almost every other variety throughout the Show. In the *Brahma* pullet class the severity of competition was such that the Committee permitted an extra premium; the Light *Brahma* pullets of Mrs. Williamson, of Leicester, than which even her highly-reputed yard never turned out a better pair, taking the precedence. A lovely pencilled pen of Dark-feathered ones, shown by Mr. Edward Kenrick, of Lichfield, ran an unpleasantly close second. Many grand pens of both cockerels and pullets were also entered, the exceptionally good quality of the winners causing great interest, and the general conviction that, with care, for months to come few can beat them. Mr. Woodgate's White *Cochins*, and the Partridge-feathered ones exhibited by the Honorary Secretary, Mr. Sheppard, were equally faultless. Six pens of this year's chickens were shown by the latter gentleman, all so wonderfully well matured that most of them were laying. Being both well marked and well selected, besides being entered at very low prices, the whole were quickly announced as sold, and well they must have paid the lucky purchasers, the six pens having previously had awarded them three first prizes, a second prize, and the remainder high commendations. *Rouen Ducklings* showed well, but the Aylesbury ducklings with the exception of one pen were deficient in purity of bill. Whistling Ducks were the winners in the Variety Duck class, a whole host of capital Muscovy Ducks being also shown.

Turkeys and Geese, though so few, were excellent show birds. There was a very good entry of *Pigeons*, many of decidedly first-class character; the Pouters, Fantails, Barbos, and Variety class being more particularly praiseworthy throughout.

As beautiful harvest weather marked the proceedings as a success, it is probable that an extended prize schedule will be issued for next season's exhibition.

Mr. Edward Hewitt, of Birmingham, was the Judge, and his awards were given in our pages last week.

A CLASS FOR BELGIAN HARE RABBITS.

I THINK, now that Belgian Hare Rabbits have become more known and are in general favour, it would be advisable for committees of shows to give them a separate class. Boston has set the example, and I believe the entry was a very fair one for a first attempt. There are, to my knowledge, many breeders of this handsome variety of Rabbit who would be inclined to exhibit were there classes for them, but who do not care to show in the variety assortment, which is generally the conclusion of a Rabbit as well as a poultry and Pigeon schedule, and so run the risk as to which kind may take the fancy of the judge.

It would be a matter of surprise to find a class for Dorkings omitted on a prize list; equally so should be the omission of Belgian Hares from one for Rabbits, as in a commercial point of view as meat-producers they are the best to keep. Hardy, prolific, of rapid growth, and excellent for table purposes—these are qualities, in the present time of a high-priced meat supply, of no mean value.

It is, I believe, generally known that this variety is a foreign introduction, and though in character they very much resemble the Hare, their properties are in no way indebted to a cross with it. Though frequent attempts have been made, no such cross, owing to the entire difference in disposition and habits of the breed, has been accomplished. A simple microscopic examination of the hairs will show the difference of the species. Belgian Hare Rabbits of a good breed with liberal feeding will easily attain 8 lbs. or 10 lbs. weight when the same number of months old. Should there be a Rabbit show, as last year, at the Crystal Palace, and this variety be allotted a class, I shall be happy to subscribe towards a cup to meet its claims.—W. MASSEY.

FIRST-FEATHER CANARY SHOWS.

THESE interesting exhibitions seem to be gaining ground in the northern circuit. They are prevalent enough in some districts, and perhaps more so among Lizard breeders than any other branch of the fancy. One would think that a good show once in the season would satisfy the most ardent fancier, but it seems not so. No sooner is the breeding season closed or closing than breeders are anxious to compare notes, and the natural outcome is a nest-feather show. Such shows must to a very great extent be local, as very young birds would not bear much travelling, nor would it be desirable they should be exposed to unnecessary risks if their owners have any regard for their future. On this account—that is, on account of their local character, any detailed review of such shows can hardly be expected to possess such interest as to be deemed worthy a place in the columns of the Journal. Still, it may interest breeders generally to know that both in South Stockton and Darlington, where I was judging last week, there has been a tolerably successful

season. Each of these places has held its nest-feather show, and, judging from the quality of the stuff, each will be able to hold its own in the forthcoming exhibition year. The young Yorkshire birds are remarkably fine, and the Lizards promise to sustain the fame of the district.

At North Stockton a splendid open Show was held in connection with the brass band contest under the patronage of the Licensed Victuallers' Association, the chief features of which were the beautiful specimens of Norwich birds exhibited by Mr. Simpson, the Whitby veteran, and the grand Yorkshire birds of Mr. Rowland and others. Mr. Simpson has bred a very superior evenly-marked Jonque Norwich which will take some beating. It is a bird full of colour and quality, has two well-pencilled eyes, and wings "made to order." The marking on the right wing runs up a little too high, though the defect is as frequently hidden as exposed, but it is there. In some hands no doubt it would soon vanish; but as Mr. Simpson said, "I have been among them for fifty years, and I'm not going to begin now." I may add that this was one of a nest hatched early in January this year. On the whole the prospects in the north are cheering.—W. A. BLAKSTON.

CRUELTY TO PIGEONS.—John Mursh, a lad living in Union Street, Swindon, was charged with cruelty to two Pigeons, on the 22nd June. Mr. Tombs appeared for the Society for the Prevention of Cruelty to Animals in Cirencester and district, and stated that the case would not be pressed if it had not appeared to be an usual pastime on Sunday afternoons. He said that two birds were tied tail to tail and thrown up in the air, then falling helplessly to the ground. Police Constable Piper substantiated Mr. Tombs' statement, proving that the birds were treated as described three times, and each time falling helpless to the ground. Fined 30s. including costs.—(*North Wilts Herald*, July 12th.)

THE HONEY HARVEST OF 1873.

IT is time that our friends should send in their reports of the honey harvest of this year. I much fear they will prove generally discouraging. In my own case I must say that I have never known a worse year in all my English experience of bee-keeping. Last year was bad enough, and the year before not much better, but what has become of the honey I cannot imagine. What is Mr. Fox's experience in the rich pasturage about Exeter, and what that of our Scotch bee-keepers? My hives were generally very late. Out of twelve stocks which survived the winter, but which had to be fed quite up to May, some of them far into the month, only one swarmed to my knowledge on the 7th of June. This gave me a cast on the 16th or 17th. I left home for a fortnight on the 8th of July, and it is possible I may have lost some swarms since then. Honey being my object this year, I gave them abundant room in supers, which they took to very kindly, building many combs, but filling them with brood and not with honey. The white clover has been very abundant, and our orchards and gardens were filled with blossoms that have produced vast quantities of fruit; but for all that honey is nowhere. Rarely have I had such splendid stocks of bees all through June and July, cramming up super upon super, but with the most miserable result as regards honey. I doubt if some of my hives will not starve in September, nor is there a single super I dare plunder for fear of ruining my bees; so that I may write down nil, nay, rather a minus quantity, as the result of this year's bee-keeping. Will any of your readers account for it on any other theory than that the ground was chilled past recovery by the long-continued rains of winter, while the sun has had little power to cure the sourness of the soil?—B. & W.

SILKWORM-CULTURE IN ENGLAND.

IT has always appeared to me that one of the great hindrances to the successful production of silk in this country is the difficulty of so winding the thread from the cocoons as to give the article a commercial value. A correspondent of this Journal speaks of it as a comparatively easy matter to connect the thread of ten cocoons (it is more usually, I believe, the product of from five to eight that is brought together), but this has not been the experience of others, who have found that the manipulation is most troublesome; and in those countries where silk forms an article of commerce it is acknowledged that to wind the silk requires special training. There may have been some machine invented which would facilitate the process of uniting the threads; if so, it has not been made generally known. The common silk-winders sold in the shops are not of much utility. To produce silk to advantage, it is evident that we must not have to expend much time and labour on the preparation of it for the loom.

Another drawback to silkworm-culture has been this: that the emergence of the worms from the eggs only takes place annually, so that the rearer of silkworms has an over-busy six

or seven weeks during the season, and then his work is done for another year: hence some have been disposed to look favourably upon such foreigners as Cynthia and Perney, which seemed to promise more than one brood in a year. But would it not be possible to bring about a retardation of the hatching of the eggs of Bombyx Mori, so as to have a succession of broods? Supposing that a part of the eggs were exposed to the sun in April, we might have a spring rearing; then from the remainder of the eggs, which had been kept back by a low temperature, we could, perhaps, get other "hatches" in May and June. There is no difficulty in obtaining food, as we know, for Mulberry leaves in eatable condition may be obtained even in September.—J. R. S. C.

A CORRESPONDENT has sent us the following remarks on the subject:—"I never found any difficulty in rearing the worms and obtaining the silk, provided I could obtain a sufficient supply of fresh food, nor did I find much trouble in reeling-off the silk owing to breaking the threads; but then it had little commercial value, because, being a single thread, it was unfitted for the purposes of the manufacturer, who had to treat it simply as "floss." A certain number of threads must be united in one strand, and it is for want of the knowledge of the proper number and the proper mode that amateur silk-growers in this country fail to make sericulture yield tangible results. I may add, that if the worms are hatched forth early there is a considerable difficulty in finding them in food. If sufficient Mulberry leaves cannot be had they will live on Lettuce, and on those of the Osage Orange (*Maelura aurantiaca*) they thrive well. I have noticed that the silk from the Lettuce-fed worms is paler than from those living on the Mulberry, while that from the *Maelura* is orange and coarser.—C."

HOW TO KEEP BUTTER COOL.—Get a large flower-pot (say No. 12), plug up the hole with a sound cork, seal it. Now put a quarter-brick or other square heavy body in the bottom, to serve as support for a second, but smaller pot (say No. 16), which must also be plugged in the same manner. Place a dish under the outer pot, and a small plate in the inner one. Put your butter in the inner pot, and cover with any cover you please, provided it be not metallic. Now fill the space between the inner and outer pot with water. The butter will keep as firm as a rock, as cool as a cucumber, and as fresh, aye, as fresh as the trip across the Atlantic in a balloon.—ACHERONTIA.—(*English Mechanic*).

OUR LETTER BOX.

HARDINESS AND FEATHERING OF CREVE-COEURS (*Staly*).—We do not consider the Creve-Coeurs as hard as the Bracons, but have no doubt but his bred in Scotland would bear the climate very well. They are, in fact, acclimatised, and are not in consequence subject to the change from France to the far north. They do very well in the cold damp climate of Lancashire. The chief thing to insure success is to have the stock on their run before the cold weather sets in. The Creve-Coeur is not only a layer but a table fowl, and in all such sizes a very important matter. Most of the old cocks have white in their topknots, and the hens the same. It is not a disqualification, but every other point being perfect the scale would go against the white feathers. If they were in any other part than the topknots they would disqualify.

POULTRY-KEEPING ON SMALL FARMS (*L. M. N. R.*).—You will gain the information you require in any of the practical poultry books. They will help you more than the expensive ones, because they confine themselves to poultry at the present time. There is no doubt it may be kept profitably. The chief point is personal superintendence. The second is feeding at day-break. The third, to turn your attention to that which will find the readiest local market, eggs or meat. The fourth is not to begin on too large a scale, but to gain experience that will justify outlay. Poultry must come to play its part in feeding the country. Half the disappointments we hear of arise from people going to considerable expense before they understand the subject.

POWL DYING WITHOUT APPARENT CAUSE (*M. A. S.*).—We are sorry we cannot tell the cause of death, but should attribute it to something the bird picked up. With chickens, as with human beings, some will die, and no cause can be discovered. Discontinue the sharps and buckwheat. Give barleymeal or ground oats in the morning, some whole corn, maize, or kitchen scraps at mid-day, barleymeal or ground oats at night. For young chickens, give at intervals of three hours bread and milk, curd, and chopped egg. Give to all as much lettuce and endive as you can.

SPANISH COCK'S FACE (*A. Fairley*).—If your cock has been running with the hens again, it is probable they have picked his face. If he has not, it is a troublesome disorder to which they are subject from the increase of the white face. You have only one thing to do—wipe the moist places as dry as possible, and put on a little powdered alum. You must use but a small quantity, and you must watch carefully, for if the evil become chronic the cock will be worthless.

COCHIN COCK AILING (*E. L.*).—We are disposed to think the Cochin cock a bad case. We killed one to-day for the same ailment. We have always thought it is partly caused by excessive crowing, and the state of the brain of the bird we killed confirms us in the belief. Cochins-Chinas are not long-lived. We have known many instances of it, and have seen cases where the birds led in the act of crowing. The Hamburgh hen will do to breed from, but will never do to show again. The defect will not be hereditary.

DISTINGUISHING SEX OF FOWLS (*Subscriber*).—Ducks sit longer than fowls. You can distinguish cocks from pullets at a month old, the comb and plumage differ; but there is more difficulty with Ducks, and, to be sure, you must wait longer.

SPANISH HEN HATCHING AND REARING CHICKENS (*J. A. T.*).—We are much obliged by your communication. We fancy few people have had so much poultry experience as ourselves. We have kept all breeds and hundreds of Spanish, but we never before had a well-authenticated case of one hatching and rearing chicks.

BRAHMA COCK WITH DORKING HENS *versus* DORKING COCK WITH BRAHMA HENS (*J. S.*).—We prefer the Brahma cock with Dorking hens.

REELING SILK.—"J. S." desires to say that the diameter of the reel should be 2 feet, not 3 feet, as stated on page 55.

GEESE WITH TWISTED FLIGHT (*J. D. L. T.*).—The Geese in question are suffering from twisted flights. There is no cure for it. It is common to fowls as well as Geese, and is incurable. There is no difficulty in distinguishing the sexes of Geese, but a certain result can only be arrived at by a close examination and careful handling.

HARVEST BUGS (*Picked Angle*).—Camphor and various odoriferous compounds have a partial effect in warding off the attacks of the Harvest Bug, and persons have also been advised to rub themselves over with tar, a remedy, doubtless, worse than the disease. These insects have, however, a strong objection to anything oily, and the merest film of oil has been usually found to keep them off; or any places particularly exposed to their attack may be damped, and then rubbed with soap, and this coating suffered to dry on the skin.

REMARKS.

- 30th.—Very fine bright day, with cool breeze.
- 31st.—Cloudy early; fine about noon; rain at 1 P.M. for a short time, but fine afterwards.
- August 1st.—Fine early; rain at 10.30, thunder and lightning soon after; fine afternoon, evening, and night.
- 2nd.—Fine all day, but rather cool breeze.
- 3rd.—Fine during the whole day, but not very bright, except occasionally.
- 4th.—Rather dull morning; fine noon and afternoon, but cloudy in the evening.
- 5th.—Dull morning; heavy rain about noon, fine soon after; but heavy rain at 3 P.M., at 5, and occasionally during the remainder of the day. A fine summer week. Although there have been no extremely hot days, the temperature has averaged nearly the same as last week.—G. J. SYMONS.

COVENT GARDEN MARKET—AUGUST 6.

The markets generally continue well supplied, and prices remain nearly stationary. The last of the West Indian Pines are just to hand, and Continental consignments are large, comprising Green Gage and other Plums, Apricots, Peaches, Nectarines, and Grapes.

FRUIT.

From observations taken near London during forty-three years, the average day temperature of the week is 73.0; and its night temperature 59.4. The greatest heat was 92, on the 18th, 1842; and the lowest cold 13.6, on the 18th, 1846. The greatest fall of rain was 1.12 inch.

ORNAMENTAL PLANTING.—No. 7.

ROADSIDE SCREENS, SELECT SHRUBS, ROSES, CLIMBING AND FLOWERING PLANTS, FOR A SMALL GARDEN.

N the immediate vicinity of all large towns there are numerous houses of a superior order—houses of taste, where attempts at gardening may invariably be seen, affording stronger evidence than anything else with which I am acquainted of the universal fondness for the pure fresh beauty of Nature. Many of the inhabitants of such houses are enthusiastic and very successful horticulturists, subscribing to the Journal, often, per-

haps, seeking for the information in its pages which they do not find, or finding, are unable to apply, because it does not plainly appear to adapt itself to their particular case; and so I purpose devoting this paper to a consideration of the formation of screens and hedges for roadside houses, with a selection of shrubs suitable for very small gardens.

It is not often that roadside screens are at all ornamental; they are, as a rule, just a confused thicket, a "rough-and-ready" and most unsightly assemblage of unhealthy shrubs, bare-limbed and dust-laden, forming a miserable disfigurement, and seriously affecting the general appearance of the often pretty garden, which, if rightly managed, they ought materially to embellish. Now, there are two ways of forming such screens so as to render them ornamental as well as useful. The first and most desirable consists of a belt of two or three rows of mixed shrubs; and the second, which is best adapted to very confined spaces, is in the form of a hedge, which form the unsightly mixed screens that are so common usually take. In making such hedges it should be taken as a fundamental rule which may not be broken with impunity, that only one kind of shrub is to be used in the same hedge, and that whatever shrub is chosen it must be of a dense habit of growth, and either of an evergreen or sub-evergreen character. Perhaps the best shrub of all which might be named for such a purpose is the common Holly; its many excellent qualities have been fully explained in former papers, and to its hardiness, density of growth, and ornamental appearance, its immunity from the baneful effects of smoke and dust may here be added as an important qualification for such a purpose. Rhododendron ponticum and its varieties are also good, and may be introduced with confidence; for I do not purpose keeping the hedge clipped to a formal outline, but would much rather plant it a few feet inside the fence, so as to let the branches have as much freedom as possible, preferring to keep them in form by judicious pruning with the knife when requisite. Then there are Yews, Portugal Laurel, double Furze, Box, Aucuba, Berberis, the beautiful Japanese and Chinese Privets, and to these may be added the Irish Ivy (*Hedera canariensis*), and the beautiful and very robust *Hederaibernica*, with its stout, glossy, heart-shaped leaves, either of which may be so trained upon woodwork or wire as to form an elegant screen.

All shrubs will not thrive equally well in the same neighbourhood, and very often it is not altogether the soil that causes failures so much as the constant assaults of foul dust and smoke, which clog the pores of foliage and branch, and the poor shrubs, uncared for till they are dying or dead, and unwashed save by any chance shower, soon become unhealthy, and if sufficiently sturdy to retain life, the puny growth and dull-hued foliage are anything but ornamental. Health may be maintained, freshness, and therefore beauty, may be imparted to shrubs that are thus exposed to adverse influences, by a free and regular daily washing of clean water by means of a syringe. Ample demonstration of the great value of this plan may be found at Battersea Park, where the portable hose appears constantly at work, the vigorous health of the shrubs showing plainly how beneficial its miniature showers are.

Mixed belts may be formed of the shrubs selected for hedges, and if more are required for variety, there might be some *Laurustinus*, *Mahonia*, *Arbutus*, *Bay*, and *Phillyrea*. Conifers do not thrive well under the influence of smoke; it may, however, be useful to note here that *Thuja Warreana* and *Thujopsis borealis* form excellent and most compact screens or hedges.

The gardens to which these notes are applicable are usually so small that the shrubs introduced into the interior should be few and select. In the following lists the shrubs named are of moderate growth, and the whole of the varieties are choice and distinct.

Twelve mixed shrubs:—

- | | |
|---------------------------------|----------------------------|
| 1. Berberis Darwinii. | 7. Spiraea arifolia. |
| 2. Arthrotaxus selaginoides. | 8. Syringa persica. |
| 3. Deutzia crenata flore pleno. | 9. Syringa alba. |
| 4. Ribes sanguineum. | 10. Tamarix germanica. |
| 5. Santolina Chamaecyparissus. | 11. Berberis japonica. |
| 6. Skimmia japonica. | 12. Retinospora cricoides. |

Twelve select Roses:—

- | | |
|---------------------------|------------------------|
| 1. Baroness Rothschild. | 7. Paul Verdier. |
| 2. John Hopper. | 8. Alfred Colomb. |
| 3. Louisa Wood. | 9. Duchesse de Caylus. |
| 4. Madame Victor Verdier. | 10. Baron Hanssman. |
| 5. La France. | 11. Mdlle. Bonnaire. |
| 6. Dr. Andry. | 12. Duke of Edinburgh. |

Six select climbing plants:—

- | | |
|----------------------------|-------------------------|
| 1. Escallonia Ingramii. | 4. Ampelopsis Veitchii. |
| 2. Escallonia pterocladon. | 5. Lonicera flexuosa. |
| 3. Ceanothus azureus. | 6. Clematis Jackmanni. |

Twelve other desirable hardy shrubs and flowering plants:—

- | | |
|-------------------------|-----------------------------|
| 1. Yucca recurva. | 7. Præmia lactea. |
| 2. Yucca gloriosa. | 8. Colonel Malcolm. |
| 3. Gynurium argenteum. | 9. Hippolyte. |
| 4. Erica carnea. | 10. Comte de Flandres. |
| 5. Hydrangea Olaksa. | 11. Pernettya angustifolia. |
| 6. Hydrangea hortensis. | 12. Deutzia gracilis. |

—EDWARD LUCKHURST.

PHLOX CULTURE.

THE varieties of Phlox pyramidalis and P. decussata are the most useful of herbaceous plants for a small

garden. They require very little attention, but what they do require must be given at the right time. We owe Mr. John Laing, of the Stanstead Park Nurseries, Forest Hill, our best thanks for raising many new and improved varieties, and also for exhibiting them in such fine condition as he did at the Royal Horticultural Society's Show on August 6th.

As a plant for the herbaceous border this has few rivals; it has also a fine effect planted in beds; but to have it in the best condition the plants must not be allowed to remain in the same place year after year without being disturbed. After the second year they begin to decline, a larger number of spikes are doubtless thrown up, but they are much weaker, and the individual flowers are smaller and wanting in shape. This is caused by the plants forming an immense number of roots near the surface of the ground, which, matted together as they are, soon exhaust the surrounding soil of all nutriment. A dressing of fresh soil does not help them much, so that the best and only way to obtain good results is to propagate a fresh batch of plants every year.

The best time to propagate the Phlox is in spring. As soon as the young shoots have grown about $1\frac{1}{2}$ inch slip as many off as required, and pot each singly in the centre of a small pot. They will root sooner if the pots are placed in a gentle hobel, but this is not necessary. They will root readily under hand-lights, or even plunged in the open air in a shady sheltered position; or a small bed of fine soil may be made in a shady place, and the cuttings inserted in it 3 inches apart.

After the cuttings are rooted, plant them out in the beds in which they are intended to flower, for each cutting will produce a nice spike of flowers the first year. If they are planted in beds they should be from 15 to 18 inches apart, and there should be about four rows in a bed, with a wider space, say 30 inches, between each bed to allow of a person getting up between them with a water-pot.

The plants will require a considerable quantity of water during the summer months, and dressing the beds with some short decomposed manure will also be very beneficial. The ground should previously be deeply trenched, and a good dressing of manure ought to be applied to it. The plants may also be planted out in herbaceous borders, where they have an excellent effect; but if it is desirable to do this, a hole should be dug out about a foot square and as much in depth, to be filled with some rich compost, in which the Phlox is planted.

It is in the second year that the best plants are obtained, but those in the beds must be lifted and replanted, and instead of the plants being from 15 to 18 inches apart, they should now be from 22 to 24 inches, and each plant will have from three to five spikes of flowers. Sticks should be placed to the spikes at an early stage of their growth, as if this is not done the strongest will probably be broken over by the wind, which snaps them at the base. Each spike should be attached to a moderately stout stick, and be tied-out in such a way that it may not be crowded by others. Some persons place one stick in the centre of the plant and tie all the spikes together in a bundle; but this, to say the least of it, is a very clumsy way of treating them. The same plants may be grown a third season, but the spikes will not be so strong though more numerous than they were in the second year. They will, however, furnish a goodly supply of cuttings, and whether the shoots are required for this purpose or not, they must be thinned-out to five or six on each plant.

The Phlox is also well adapted for pot culture. When the plants are intended for this purpose it is best to insert the cuttings in small pots at once, and as soon as they are well established to shift them, the weak plants into 5-inch, and the strongest into 6-inch pots. The following compost suits them well—viz., four parts good turfy loam, one part leaf mould, and one of rotted manure, with the addition, if necessary, of a little sharp sand. During the period of growth, and up to the time of the first flowers opening, the plants should be out of doors, and in a position where they get all the sun possible; at the same time the Phlox is much injured if exposed to driving winds. The more dwarf and compact the plants can be grown the better; thick stems and sturdy growth will be the result of good culture. The pots should be plunged in some cocoa-nut fibre refuse, or any other material—ashes, leaf-mould, &c. When the pots are well filled with roots give a supply of weak manure at every alternate watering. The plants, if removed to the greenhouse as soon as the first flowers appear on the spikes, will continue in beauty a very long time. The flowers are delicately scented, and form a very distinct and pleasing feature either in the greenhouse or conservatory. When the

flowering period is over the pots may be removed to a cold frame for the winter, where they must be plunged to prevent the roots from being injured by frost. The second year these will form noble flowering plants, throwing-up stout flower-spikes from 2 to 5 feet high. They should be repotted in February in 10-inch pots, using the same compost I have previously recommended, and the same treatment throughout. If it is necessary to retard them for some particular purpose, instead of removing the pots to the greenhouse, place them under a north wall, providing some shelter, in the shape of old lights, to prevent the rain from dashing the flowers off.

In a future number I will give an estimate of sorts. Many of the best varieties of the *P. decussata* section used to be raised in France, but our English raisers have now equalled, if not surpassed them. The *P. pyramidalis* section is very beautiful, and the varieties belonging to it succeed best in the more cool and moist climate of Scotland, where the best varieties have been raised.—J. DOUGLAS.

NEW STRAWBERRIES.

The season now rapidly passing by has been so favourable to the general Strawberry crop, that it has enabled me to pronounce a definite judgment on some of the numerous seedlings I have had under my notice for the last four or five years, and which I have been reluctant to name until I was perfectly sure of their value. It will be recollected by some of the readers of the Journal that I commenced this favourite pursuit some few years ago by endeavouring to improve the race of early and late Strawberries. Of midseason varieties we have abundance, unless some new quality should be developed, such as better and more certain cropping, better packers and carriers, &c., which qualities are so desirable as even to justify new main-crop sorts. I think it will be acknowledged by all who have grown Early Prolific well, that the class of early Strawberries was improved by the introduction of that handsome early sort. It is true it was not quite so early as Black Prince, but it is quite early enough to withstand the spring frosts we are invariably favoured with throughout Great Britain, and perhaps in the midland counties more particularly: whilst the quality of the fruit is in every way so superior to Black Prince that it scarcely needs mention. I have still the seedlings of Marguerite under observation, and these I have reduced to three, one of which I have named Alpha. This is earlier than Early Prolific, and as early as any good-sized fruit with high flavour can be ripened out of doors in this country; but it will take another season to get up a good stock of plants.

The following new kinds will not disappoint the most fastidious grower either in growth, bearing, or quality. First in order of succession comes

Early Crimson Pine.—This is a fine, large, handsome fruit,

Early Crimson Pine.

coming in with or closely succeeding Early Prolific. The prevailing shape of the fruit is indicated by the accompanying woodcut. Colour bright crimson; calyx generally reflected; seeds rather prominent; flesh dullish white and sometimes pink, juicy, with a rich piquant pine flavour. The plant is of stout upright growth, and crops heavily.

The Countess comes next. This kind will prove the best packer and carrier ever raised. The fruit is extremely fine in colour, being of a beautiful glossy crimson, and becoming darker when very ripe. It is not quite so regular in shape as the other varieties under consideration; but the fruit is so

The Countess.

good, its colour so handsome, and, above all, its carrying property so remarkable, that its occasional irregularity in shape is quite condoned. Calyx partially reflected; seeds thickly disseminated and decidedly prominent; plant healthy and a good grower; foliage bright glossy green, erect, and compact. This and the above variety, I regret to say, cannot be offered to the public till next season.

Sir John Falstaff is next in order. This is a midseason and main-crop variety. The predominant characteristics of this, a different strain altogether from the foregoing, are its hardihood and enormous cropping qualities. It has never disappointed me in a heavy crop from the first seedling plant, which

Sir John Falstaff.

struck me with astonishment. The fruit is mostly very large and handsome, frequently conical, and when very large slightly flattened in shape, as in the woodcut, but never cockscomb'd. Colour bright red with a tinge of vermilion; seeds thickly dispersed and slightly depressed; flesh white, solid, and juicy, with a fine vinous flavour; calyx small for so large a fruit, and seldom reflected. On account of its beauty and immense cropping qualities this will be a splendid sort for exhibition and market purposes, but it would not carry a great distance so well as the Early Crimson Pine, or Countess more especially, nor, indeed, would any other known sort.

Enchantress comes next. It is a late variety, coming in with and lasting out British Queen, but higher-flavoured and a

better cropper than that esteemed good old kind. This is the variety I originally named Lord Napier, but I was advised by several of my horticultural friends to substitute another name, fearing it might be confounded with Sir Charles Napier; and every year it has so won upon my good opinion and that of

Enchantress.

everyone who has seen it and tasted its fruit, that I have adopted the above name. I think it will be admitted by all who like a highly piquant fruit with a rich pine flavour, to be the finest flavoured Strawberry ever raised. I have tested this variety in every possible way. Though naturally a late sort, under a south wall it makes a grand second early, whilst under a north and east wall it comes in with Cockscomb and Frogmore Late Pine. It requires a little sugar to bring out its fine pine and Hautbois flavour, and then it is perfection. Fruit large and of the prevailing shape of the annexed woodcut, but frequently conical, and then it has a glossy neck and reflected calyx; colour scarlet, becoming a rich crimson when fully ripe; seeds small and prominent, bright yellow, and very thickly disseminated; flesh reddish, solid and very juicy, with an exquisite pine flavour. A first-rate cropper, bearing its fruit in clusters on shortish footstalks, so that its blossoms and fruit are considerably hidden under and amongst its handsome, slightly wrinkled, light green foliage. This and the above I think it is possible my gardener may try to bring out in the present autumn; but if so the stock will not be very large, and the plants must be issued in small numbers.

I have many other valuable deviations from the ordinary run of Strawberries under observation, but I must content

Gipsy Queen.

myself for the present with one more illustration—viz., *Gipsy Queen*. This I may introduce one of these days on account of its beautiful dark colour, thus forming an excellent contrast in the dessert. The fruit is chiefly globular, or nearly so, but sometimes a blunt cone-shape, almost black when quite

ripe, extremely juicy, rich, and vineous. Flesh dark red throughout; ends depressed. Plant of low growth and compact, healthy, and a great bearer. Season, main crop and late.

Out of the same strain I have also another which I call *Fair Lady*, in which the fruit, however ripe, never colours deeper than a salmon pink. This forms a direct contrast to the above, though reared from the same Strawberry, and is a nice sharp-flavoured fruit, which some would have called Pink Elton instead of the above name.

I have another seedling which I must just mention and then say good-bye to the Strawberry world for the present—viz., *Excelsior*. There are several *Excelsiors* I find, so probably I may have to change the name of this variety. Besides being a very handsome late fruit, and, perhaps, the best-behaved sort under glass, with very high flavour and excellent colour, its runners have the property after the parent plants have ripened-off their fruit, of blossoming all over the beds till the beds are one mass of bloom. I am aware that several kinds, *La Constante* among the rest, have this property to a limited extent; but in the above variety, which is a second remove from Cockscomb (by which I have quite got rid of the cockscomb shape), and which has nothing to do with the *La Constante* race, the beds become laden with fruit till frost sets in. *Fragaria tardissima* is just now beginning to colour its fruit. This kind throws-off a moderate quantity of fruit during August, and sometimes to the beginning of September, and by this time the *Excelsior* runners are setting their fruit, and continue bearing till the first severe frost. I have no doubt, therefore, that if these runners were potted-off before the autumnal frosts set in, and duly cared for under glass, say in a moderately warm frame, Strawberries of excellent quality might be had till the approach of winter, thus making it possible to produce this charming fruit eight months out of the year.—W. RODEN, M.P., *Morningside, Kidderminster.*

MESSRS. BACKHOUSE & SON'S, YORK.

To be a florist, and at the same time a lover of Nature's flowers, is considered to be well nigh an impossible conjunction; and therefore those who have been in the habit of regarding me simply as a bigoted old florist, will be perhaps surprised to see me put my hand to the statement that I have never enjoyed a ramble through a nursery so much as I did a morning's visit to my valued friend James Backhouse, of York; and I am sure of this, that no botanist that ever lived could have felt more intense pleasure at the discovery of some new or rare plant than I did last year when I came upon those glorious masses of *Gentiana alpina* and *Silene acaulis* on the top of the Col de Bane last year. They are common flowers enough, but to see them thus in all their native vigour and beauty, and in the midst of such surroundings, was a thing worth experiencing. I have ever believed that my love for flowers was not measured by their exhibition value, and one proof of this, which I cherish, is my love for wild flowers, and especially Alpine flowers, and that, as I say, without being a bit of a botanist.

Everyone who owns a garden, and is acquainted with what is going on in the horticultural world, has heard of the York nurseries; and it was, therefore, with no ordinary expectations that I wended my way thither on the day before the Great Yorkshire Gala, and would gladly record my impressions of its wonders; but I have ever felt when writing of any place that really merits praise, how difficult it is to give any adequate idea of it, and in reading descriptions of scenery it is ever the same. Who has ever enabled one to realise the grandeur of Alpine scenery? or would Byron's description of the storm at sea bring it home to one who has never seen the wild waves tossing to and fro? I must, therefore, crave indulgence if what I write seems to those who have never seen what I attempt to describe poor and tame, and if it fails to convey any adequate impression to those who have not been there. I am not going to attempt a general description of Messrs. Backhouse's nursery of seventy-two acres, with its ranges of glass, Orchid houses, &c. It will surprise no one to hear that these are admirably kept, and that many a treasure is to be found in their recesses. Nor shall I venture to write of their fernery, with its noble tree Ferns and rare and valuable species, for I have seen others, at least one other, which, if my memory serves me right, exceeds it—viz., Mr. Bewley's, of Black Rock, in Dublin, which I endeavoured to describe a few years ago in the columns of this Journal; but there were two special objects of interest which to me were utterly new—I

mean the Alpine garden and the underground fernery. I have seen Alpines growing in other places; I have seen, for instance, the Rev. Mr. Ellacombe's, of Bitton; but nothing I have ever seen can for a moment bear comparison with that of Messrs. Backhouse's, while their underground fernery is, I believe, unique; and it is of these I now write.

Everyone who knows York is aware of the very level nature of the surrounding country; but when standing on the lawn in front of Mr. Backhouse's house you might imagine yourself in the neighbourhood of Tunbridge Wells or some such rock-abounding place, for at immense cost and with a great deal of trouble a large quantity of rock has been brought together, and so judiciously and naturally have the rocks been placed that you seem rather to be looking on a place whence stones have been quarried, and where, as in the Buttes Chaumont at Paris, the ground has been afterwards utilised for a rock garden.

In the construction of the Alpine Valley some hundreds of tons of stone have been used, and with such effect as only could have been gained by a skilful and tasteful eye; and in this valley have been arranged without doubt the most varied, extensive, and valuable collection of Alpine plants ever brought together. At the period of my visit the *Gentians*, of which there is here a fine collection, were over, but *Dianthus*, *Aquilegia*, *Cistus*, *Iberis*, &c., were in full beauty. What can be more lovely than the clumps to be seen here of the lovely *Dianthus neglectus* with its bright cherry carmine flowers, or alpines with deep rose or flesh-coloured flowers spotted with crimson, and not rising above 3 inches from the ground? Then there was *Dianthus cruentus* with deep red flowers in clusters, but not so compact as the two previously mentioned. *Aquilegias* were deeply interesting. Foremost amongst them was the comparatively rare *A. leptocera lutea*; it has large golden-yellow, long-spurred flowers, which are produced in great abundance. It is apparently entirely different from *aurea* which has been lately seen in London, as its flowers are more like *cerulea*, while *lutea* is more like the common *Columbine* in form. Then there were fine clumps of the beautiful *Aquilegia cerulea*, which has proved to be a most lovely and easily-managed species; it seeds freely, and is easily raised from seed.

Some of the Forget-me-nots were in great beauty. Nestling down at the foot of a large rock was a lovely mass of *Myosotis piccola*, the most lovely of all the genus; very dwarf, and with flowers of a deep violet blue. It is a native plant, is never found at a lower elevation than 2400 feet, and delights in a shady spot or in a northern aspect. *M. montana* was nearly over, and is the same as *M. dissitiflora*, of which so much has been said lately. Another blue flower of singular beauty was *Lithospermum petraeum*, a shrubby species profusely covered with heads of porcelain blue flowers; while the older *L. prostratum*, or, as it is often erroneously called, *fruticosum*, with its deep brilliant blue flowers, was growing in great luxuriance. Of the *Gentians* still remaining in flower was the lovely *Gentiana bavarica*, difficult to manage, but charming when caught in its beauty. Of the *Lychnis* tribe there was *Lychnis Lagasææ*, a beautiful species from the Pyrenees, of a bright rosy carmine colour; and *alpina*, not rising more than 4 inches, with dense heads of rose-coloured flowers. Those somewhat difficult flowers to manage, the *Andromedas*, were represented by fine clumps of *Andromeda fastigiata* and *tetragona* with their beautiful, waxy, Heath-like bells. Ah! I wish I could convey to the minds of those who read this barren story an idea of the Alpine summit to which we gradually wound our way, where, placed on various aspects and under varying conditions, were to be found some of the greater rarities of the collection. Here, planted out in various places, was the rare and curious *Lewisia rediviva*. It forms rosettes of leaves 2 or 3 inches long, and after they have attained their full growth the plant is covered with a profusion of the most lovely flowers, shaded pink with a white centre. It is recorded of the first specimen introduced into this country that it had been dipped in boiling water and then pressed for an herbarium specimen for nearly two years; it then showed signs of life, and eventually grew and flowered. It can hardly be difficult to grow after that. Here, too, was the beautiful *Pinguicula vallisneriaefolia* from the mountains of Spain, with beautiful lilac-purple flowers. *Eritrichium nanum* is another lovely Alpine with dense dwarf foliage, with blue Forget-me-not-like flowers. It is a *bonne bouche* for snails, who will not leave it alone, and it therefore requires to be very carefully watched. And what a lovely thing is *Iberis juemunda*, with its bright purplish-pink flowers on tufts of foliage not more than 4 to 6 inches high! and how at once it catches the

eye! But I must stop for the present, and on another occasion note a few more of these beauties, and also attempt to describe the unique underground fernery.—D., Deal.

SHADES AND SHELTERS.—No. 4.

NOTWITHSTANDING the utility of the well-known bast mat for the winter protection of plants in minor glass and other structures, mats made of straw will be found equally effectual in keeping out frost; and although the former may be preferred for more than one reason, a store of straw mats is a necessity where much temporary covering is required. Where straw is plentiful they can be made easily and cheaply, and afford suitable employment for the men in wet weather; I will therefore give a few instructions on making them.

Instead of the very common way of making these protectors by simply lacing the straw between several poles, it would be much better to make them as shown in *fig. 12*, upon a wooden

Fig. 12.

framework, the construction of which I will endeavour to describe. The frame may be made of any convenient length; A, A, are the side bars, which should be cut to the length of the longest mat that is likely to be made; these are supported at each end by cross bars B, B, which are also made long enough to allow of the side bars being shifted for the making of a wider mat. After deciding upon the size of the mat to be made, get some stout string or rope yarn, and fasten several pieces at regular distances apart as shown in the figure, to one of the cross bars at either end. Pass each of these through the holes in cross-bar C, which can be shifted up or down the longitudinal ones, as the maker requires either a short or long mat. Its principal use, however, is to keep the cords in their proper positions so that the tying may be both neat and strongly done. For a mat 3 feet wide four cords will be sufficient, but for one from 4 to 5 feet wide six cords will be required; each of these cords will need to be three times the length of the mat to allow for tying and binding. This done, select the straightest and best rye or wheat straw that can be had; then, beginning at one end, lay it on crosswise in very small quantities, and bind it as you go on. Always take care to put the cut or lower ends of the straw to the outside, leaving the top or corn ends to meet in the middle. Press the straw tightly, and keep it to a uniform thickness of about an inch. Lace it tightly to the longitudinal cords making every stitch fast by itself, so that if one should by chance be undone or broken it will not loosen all the rest. When the desired length is worked up fasten each string off securely, and with a pair of clipping shears take off all loose straws and clip the sides square, then release the mat from the frame, and you will have one of the neatest and most useful of protectors. It will be a saving of time, and the work will be much better done, if two men be employed to each mat, and the framework placed upon a bench instead of on the ground, which would oblige the men to stoop.—Tues. Record.

BURN STEMS.—Mr. Wright (page 94) observes that no stems are blue. He has forgotten *Eryngium amethystinum*.—G. S.

TREE STRUCK BY LIGHTNING.—During the thunder-storm which passed over this neighbourhood on the 22nd of July, the lightning struck a large Oak tree. It commenced at the top of a small branch, following it to the centre or body of the tree.

The body of the tree is very crooked, and the course the lightning took was exactly down the centre or body. In its course downwards it came in contact with a small branch, which it cut off, passing down to the roots. Do you think the centre of the tree attracted the lightning in any way, as the course was very crooked? This tree is causing a great deal of talk, and has been seen by thousands of people. It stands close behind the hotel at Eastham Ferry, on the Mersey, Chesbute side.—JAMES R. POCCOCK, *Brombrough Hall Garden, Cheshire*.

NEW PEAS.

JUST a word about some of the new Peas. The following have been proved by me to be truly excellent, and anyone who produces a really good thing, be it a new vegetable, flower, or fruit, deserves his meed of praise as a public benefactor.

James's Prolific is everything described by Messrs. Carter and Co., a very handsome white wrinkled variety, about 3 feet high, with fine large pods of a light green colour, containing from six to nine large peas of the finest flavour. This is a grand Pea, and ripens off its crop pretty much at one time, so that the ground can be at once cleared for some other occupant. I am so much pleased with this Pea that I intend to adopt it for my principal mid-season crop, sowing it at proper intervals for rapid succession.

Blue Peter is another first-rate variety, and as a dwarf Pea, attaining only about 18 inches in height, is, to my mind, a great improvement on Beck's Gem, Little Gem, &c. The pods are dark green, larger than the above varieties, and contain from five to eight, and sometimes nine, large peas of excellent quality; a capital bearer, and early. I intend also to plant this extensively next season, to come in before the previous sort. A large quantity of good peas may thus be grown on a small piece of ground without the expense of stakes.

G. F. Wilson is another new Pea already favourably noticed. This is an excellent variety, similar in character to Veitch's Perfection, but growing, perhaps, a little higher and a better bearer. The pods are large and handsome, containing from seven to nine tender deliciously-flavoured peas, and, being a little earlier than Veitch's Perfection, this will be sure to become a general favourite; indeed, all three of the foregoing sorts have worthily merited the approval of the Royal Horticultural Society.

A worthy successor to the above to finish the season is Williams's Emperor of the Marrows. This has been thought by some persons to be only a good stock of British Queen. I cannot help thinking, however, after two years' experience, that it is more branching in its habit, and certainly pods lower down on the haulm, than that variety. I believe it to be as good as British Queen (no mean praise), and its crop is something wonderful, the plant continuing to bloom and pod till frost sets in. This sort should not be planted too early in the season, otherwise it attains a height almost unmanageable. If planted about the 1st of May, it commences to ripen off its first pods about the present time, and is then a reasonable height, and keeps bearing till the end of the Pea season.

For early work, Laxton's William I. will become a favourite, and Alpha is liked by most judges of a good Pea. Its only drawback is that it chiefly bears its pods singly; but it is so tender and good in quality that it must be grown among the first earlies in every good establishment.—WILLIAM ROBERT, M.D.

DISEASED POTATOES.

MR. BRÉHAUT's is the first instance that I know on record of the disease presenting itself so early as April in this country or in Europe, when (as the Editors say in noting the breaking-out of the disease in Sussex, page 84), "it cannot be said in this instance that electricity and electric storms have contributed towards the development of the disease." Mr. Bréhaut alludes to the manure employed being too fresh, which would have the effect of inducing a grosser growth than if older and less stimulating manure had been applied; and are not the Potatoes with gross haulms, made gross by the application of manures, the most violently attacked by the disease? Why should the planting in old garden soil which had last season borne good and bad Potatoes, give to the succeeding crop the disease? Are the germs of the Potato disease in the soil? I believe not, for on ground that last year produced more than 100 bushels of good Potatoes they are found, and the seed was of the same

diseased stock grown on the same ground last year, also the year before. The soil might, from being rich, added to the fresh dung, have caused that development of the Potato haulm suited to the growth of the Potato fungus. In no other way do I think the soil would have influence on or contribute to the appearance of the disease, for I do not find there is any difference as to the susceptibility of Potatoes on fresh ground well manured, and those having a change of ground, or grown year after year on the same land. This year, I am glad to say, we have not found a diseased tuber in heated houses and frames, in cold frames, or in the open ground. Mr. Bréhaut may plant in the same borders next season without fear of the disease—even plant diseased tubers, and of the latter I can answer that he will have sound tubers. Neither planting sound Potatoes in ground which has produced diseased Potatoes, nor planting diseased ones, will produce the disease. This attacks the haulm first, then the tuber. Stay its progress in the haulm ere it descends to the tuber, and the latter will be safe.—G. ABBEY.

P.S.—Now that we have the disease appearing in great virulence in Sussex, it may not be amiss to direct attention to that never-failing remedy—the pulling-up of the haulms when they are first noticed to be spotted and blackened by the fungus. Do this, placing the feet alongside of the haulms, so as to keep the Potatoes from being drawn from the soil along with the haulm, and we may at least have a fair crop—often as heavy as if it were left to mature. The tubers may be waxy, but they improve immensely after being taken up and stored dry.—G. A.

GOLDEN CHAMPION GRAPE.

On paying a visit some two years back to an amateur friend of mine in this locality, I was surprised and very pleased to find this glorious Grape in its Sunday dress, and with no appearance of spot. On inquiry I learned it set well without any artificial means having to be resorted to. I could see it swelled evenly, and was of a fine amber colour, with berries of a prodigious size. On inquiring about its history I learned it had been grafted on a strong-growing white variety which my friend did not know, but supposed it to be Royal Vineyard.

Profiting by the hint I went home fully determined to go and do likewise. Therefore on the 1st of March I cut down a Royal Vineyard Vine, which by the way is none of the best, and then grafted on it, on the bottle system, one of the Champion. It made a splendid cane, and I am this season rewarded with seven bunches of Grapes that set freely, swelled their berries regularly, and are now approaching ripeness with scarcely any spot, but I can afford a little spot on such a grand Grape as this. I ought to mention that the bunches are not large, but compact and beautiful.—R. GILBERT.

FLOWERS FOR OUR BORDERS.—No. 14.

CEANOTHUS DENTATUS.—TOOTHED CEANOTHUS.

With a few exceptions the plants of the Buckthorn family are not remarkable for the beauty of their flowers; the *Ceanothus*, introduced to this country from California, will, however, do much to increase the interest attached to this tribe. The flowers are, individually, very small, but this minuteness is fully compensated for by the profusion with which they are produced. The foliage, too, is extremely neat, especially in the species selected for our illustration, and which is, perhaps, the most interesting of the genus. Some fears were entertained that the *Ceanothus dentatus* would prove only half-hardy; the specimen from which our figure was drawn was, however, taken from a plant which had been fully exposed on a south wall throughout the winter without any protection whatever, and as its capability of resisting our winters will doubtless increase with the age of the plant, we trust that this charming species may be considered acclimatised. Like many other shrubs cultivated in the open air, it would probably suffer considerably from severe frost; but as the peculiar habit of growth, both of *dentatus* and most of the other species, renders it desirable that they should be planted against a wall, the protection of matting can be afforded them without entailing much trouble or expense.

The *Ceanothus dentatus* is a branched evergreen shrub, growing to the height of 7 or 8 feet, perhaps more. The whole of it is covered with down, that on the branches being of a rusty colour. The leaves are very small, the largest scarcely exceeding three-quarters of an inch in length, with coarse teeth, a revolute margin, and a pair of small scale-like stipules at their base. The foliage has a peculiar, but to us not unpleasant

odour, due to the numerous minute glands on the edge of the leaves, which are, however, hardly perceptible without the aid of a lens. These glands are said to be found only on this species, and they afford therefore a ready means of discrimination. The flowers are produced in stalked heads, sometimes roundish, but in the wild plants much longer. Although small, the number in each head is considerable, and their bright bluish-violet tint gives the plant when in bloom an exceedingly attractive appearance. A detached blossom is represented on an enlarged scale in the corner of our engraving, chiefly for the purpose of showing the peculiar form of the petals of the plants of this order. These, it will be seen, are much longer than the sepals; narrow and hooded (cecellate) at the tips in a curious manner, the stamens being inserted opposite the petals.

With regard to the culture of the different species of *Ceanothus* from California, they all appear to thrive in peat,

Ceanothus dentatus.

either alone or mixed with a little loam. Their growth is somewhat straggling, and the shoots, therefore, require frequent stopping during the summer; but as the flowers are borne upon the shoots of the previous year, this shortening process must not be performed late in the season. In the Osborne gardens *C. dentatus* is trained on the horizontal system, and after flowering the secondary branches are shortened back to within an inch or two of the main laterals.

The species are readily propagated by seeds, which are sometimes matured, and which should be sown soon after gathering, or they will not readily vegetate; they may also be increased by cuttings of the half-ripened wood under a hand-glass.

We have selected *dentatus* as being, on the whole, the most desirable species; but it forms but one of a group introduced, we believe nearly about the same time, by the Horticultural Society's collector, Mr. Hartweg, and which are all well deserving attention. The *C. papillosus* and *C. rigidus* are scarcely less interesting than that we have figured, and are a shade more hardy; indeed, we believe they may be said to be perfectly so. The foliage of *C. papillosus* is much larger than that of *dentatus*, and has its surface covered with pimple-like elevations, to which it owes its specific name. It is of more vigorous growth than the Toothed *Ceanothus*, and may be treated in a similar manner. *C. rigidus* fully equals in interest *papillosus*, but is less branching in its habit. It is, probably, hardy enough for cultivation as a bush or standard in this

country. Two species of more recent introduction, *C. floribundus* and *C. Lobbianus*, deserve especial mention as highly ornamental subjects. Both have blue flowers copiously produced.

One species, the *C. americanus*, is known as the New Jersey Tea, from the circumstance of its having been used in the American War of Independence as a substitute for the Chinese plant. Numerous varieties of this deciduous species have been raised in European gardens, some of which are well deserving of cultivation. As we may not soon have occasion to notice this order again, it may be worth while to remark that to the Buckthorn tribe belongs the Lotus of the ancients and the Jujube tree, both of them species of *Zizyphus*, though the articles sold as jujubes probably contain as much of the genuine fruit as the perfumer's bears' grease does of the real Bruin.—W. THOMPSON, Ipswich. — (*English Flower Garden*, Revised by the Author).

STRAWBERRY CULTURE.

I do not like to differ from your correspondent, Mr. Luckhurst, and I seldom have occasion to do so, but in his last communication on Strawberries he says, "No Strawberry plant will continue in full bearing longer than two seasons. It is true that fruit may be taken for several years from the same plants, but such fruit is invariably of a paltry description, quite unfit for dessert." Now, this is much too wide and sweeping an assertion, especially where he goes as far as to use the word "invariably." I have for some time been convinced of the fallacy of supposing that Strawberries under proper treatment cannot be made to succeed, not for two or three years only, but for many seasons, and the experience of the last two years has fully convinced me that this perpetual renovation of Strawberry beds is unnecessary. When removing some old beds five years ago I kept a portion on for trial. These plants have continued to go on bearing, not merely, as Mr. Luckhurst would have it, fruit of a paltry description, but a superabundant crop of fine fruit, and they were as fine and as full of fruit this year as ever. I use the word plants, not beds, advisedly, because the plants have always been kept distinct, and the runners cut off every year, and according to the best of my belief they have now been in bearing ten years. I have had in bearing this year beds fruiting for the third, fourth, and fifth seasons, and I cannot perceive any deterioration, and this not with one sort only, but with many, as President, Rivers's Eliza, Sir Joseph Paxton, Carolina Superba Myatt's Eleanor. Some sorts that fruited last year for the second season have, undoubtedly, borne finer fruit this the third year; and in parallel beds of the sorts I have named above I could see no difference between the fourth and fifth-season plants, and that not a scanty crop or small fruit, but fruit fit for the exhibition table and in enormous quantities.

I gave my method of treatment last year, and I need not repeat it in detail. It is merely to keep the plants separate and distinct by cutting-off the runners as soon as possible after the fruiting season is over. Mulch with good manure during the winter, put on either in October or November. (I do not think it a good plan to put it on too soon, as it induces the plants to grow instead of ripening the crowns.) I remove any mulch there is left, but which is generally very little, as it is usually washed in to the roots during the winter; but if any is left I remove it in April, so as to admit full sun to the roots till the flowering season. The beds are then copiously watered, and covered with a mulching of chopped straw laid on thickly, so as to be a clean bed for the fruit, and to keep the moisture from evaporating. I never allow a hoe, fork, or spade, no pricking-up the soil or loosening the ground, but it is kept as firm as possible. I know many, if not most, Strawberry-growers on light soils pursue a plan, if not identical, yet very similar to this; but I have briefly repeated this in order to ask other Strawberry-growers to try with me how long Strawberry beds may be continued in full bearing with fine fruit under this treatment. I have determined to destroy no beds of the sorts which I have selected as the best with me till I find they have deteriorated from the previous year.

And now a word as to sorts. I cannot endorse the encomiums passed on Vicomtesse Héricart de Thury, nor did I ever find any of my numerous friends who have tried the different kinds of Strawberries in my garden this year, who ever eat more than one or two on trial; and having had several Strawberry parties this year, when five, or six, or more dishes

of Strawberries were put on the table, I never in one single case knew the Vicomtesse preferred. It is a good, useful, hardy sort, a free bearer and early, but only fit for the cook. La Constante is another sort very highly praised which does not do well with me, and I do not think it suitable for light lands. I do not pass sentence on it, as I do on the Vicomtesse, because in the case of the latter it does not fail from want of growth or crop, but La Constante, though bearing freely, does not yield any fine fruit, at least not to compare with others. I have not suffered from damp as Mr. Luckhurst has, but Lucas has still been as good with me as last year, when we had too much wet. Filbert Pine, though a fine-flavoured Strawberry, has not liked the dry season as well as the wet. Bonne Bouche, Triomphe de Paris, and Princess Dagmar have been remarkably good; but for all general good qualities Sir Joseph Paxton is still my favourite. I forgot to mention Dr. Hogg, which is an undoubtedly fine fruit; and here I can fully endorse Mr. Luckhurst's opinion, though Frogmore Late Pine proved a failure.

I do not, by the way, like crinoline wires and other supports for Strawberries; the stem on which the Strawberry grows is easily injured, and the bend it often gets over a wire support checks the growth of the fruit. If plenty of chopped straw is used Strawberries will not suffer either from dirt or damp. Nothing to my mind injures Strawberries more than the direct action of the sun. We had thousands of berries injured here during the extreme heat of the 19th and 20th of July, when the heat in the shade was 87° and 92°, and wherever the fruit was not shaded by the leaves, it was burnt by the sun or turned a dull colour, all the freshness and brightness taken from it. We had, however, so much fruit that we could easily spare some. I think, however, the season might be prolonged and the quality of the fruit improved, if either tiffany shading or thin calico were used during very sunny weather.

I am, I fear, rather an unbeliever in recognised theories, and I do not believe that firm well-trodden soil evaporates quicker than loose and porous soil that has been forked-up and dug deeply. My experience has been, in light land especially, that if you dig into a piece of firm land, or land that has been trodden, it will be found more moist 2 or 3 inches from the surface than land that has been hoed and stirred. I know that it is the general custom to state otherwise, and to say that surface-stirring checks radiation. If air were always charged with moisture, then pulverised soil would be more capable of absorbing the moisture than a trodden surface, but then air is not always charged with moisture. On the contrary, the air that permeates the ground will generally oftener extract moisture than give it; and if this theory were true, why toss hay about and leave it as light as possible, instead of leaving it flat and pressed? Many a Turnip crop is permanently injured from the soil being worked and pulverised, and left too loose when sown. If wet weather follows no harm is done, but as a general rule Turnip land should be ready three weeks before sowing, and should be allowed to settle, when it will retain the moisture longer, and will be a better seed bed for the young plants than one which is worked and harrowed up to the time of sowing. I do not pretend this is an invariable rule on all lands, but I do mean to question, and that seriously, the statement so often made that surface-stirred land retains its moisture longer than that which is wheeled.

I am led to these remarks partly from thinking Mr. Luckhurst's plan of very deep digging for Strawberries unnecessary, and also from the extract in the last Journal from the *New England Farmer*. If, as Mr. Luckhurst says, he put 6 to 8 inches of manure on the top of his light soil, he thereby added more surface soil than many of our poorer soils above the chalk rock contain; this alone, without digging 18 inches deep, would insure a prolific crop of Strawberries.—C. P. PEACH.

THE HABIT OF THE RATA (METROSIDEROS ROBUSTA).

It will be as well, perhaps, and I hope not out of place, to record the opinions of others besides those of Dr. Kirk, which appeared in the "Transactions of the New Zealand Institute," and were given by you on pages 66 and 67 of the present volume of the Journal.

About the Rata tree in New Zealand Mr. Edward Jerningham, Wakefield, writes in his "Adventures in New Zealand" at page 336, vol. ii., as follows:—"Our method of assignation had been one peculiar to the natives—we were to start when the Rata should be in bloom. This is a curious but very common plant, which is at first a parasite, winding round large

trees of the forest till it encircles and destroys them, when its numerous coils join together in one hollow trunk, leaving the victim to rot inside. The Rata thus full grown is certainly the monarch of the New Zealand forest. In the gnarled form and tough contortions of its limbs it much resembles the Oak, and is therefore highly valued by ship-builders for knees and timbers. The foliage has also the noble appearance at a distance of the English forest king; but the plant is of the Myrtle kind, and bears a bright crimson blossom in such abundance that, at its time of flowering, the forests look as though some playful giant had dipped every other tree in crimson dye and stuck them up again. This tree is somewhat irregular in its flowering, and earlier in some parts of the country than in others; but this fairy hue is generally thrown over the wooded steep about the middle of summer, near harvest time."

In respect to what Mr. Wakefield says above about the natives, they are just the same up to the present day. On the subject of winds the natives are practically even more observant than Europeans; their notice of physical phenomena is also acute and discerning, and I find them in this part of New Zealand, contrary to the hastily-formed opinion of a few writers about New Zealand, a very industrious class. One word about Mr. Wakefield: he is one of our colonial M.P.'s, now representing the east portion of the city of Christchurch.

Mr. J. C. Bidwell, in his "Rambles in New Zealand," says about the Rata—"The Rata (*Metrosideros robusta*), in my opinion the monarch of the New Zealand forest, is occasionally found very large in the woods, but prefers a more clayey and hilly soil. It is often 60 feet high without a branch, and from 4 to 5 feet in diameter. The wood is a fine pale brown, equal to mahogany in beauty and African Oak in hardness and durability. It is a first-rate ship-building wood, but on the east coast is rare; as you approach the west coast it becomes common. It belongs to the Myrtle family, and is very closely leaved, with small brilliantly green oval leaves growing by threes around the stem; the flowers are very numerous, small, and scarlet (I am told). I have climbed many trees, but never succeeded in finding any seed nor seed-vessels in any state of decay, but once found three young plants; they were growing in a rotten branch high from the ground, and had roots very much like potatoes, and as large in one instance as a walnut. This accounts for the natives saying there are never any young Ratas. I have no doubt that, like many trees of tropical climates, they never grow from the ground, but to it—that is, they strike root in the branches of another tree, and afterwards send roots down to the soil through the trunk of their supporter as it decays. It would be a magnificent ornamental tree in England if it would grow (which I think possible), as it would be utterly unlike any tree at present known in Europe. The foliage being very dense at the extremities of the branches, but nowhere else, it looks like a number of small trees, such as Box, growing out of one another, or out of the gigantic stem of an Oak."

"*Metrosideros lucida*, a beautiful tree of this order, occurs as far to the south as Lord Auckland's Island, in lat. 50½° south."—*J. Haaker*.—(*Lindley, Vegetable Kingdom*.)

"The Ake-Ake, a New Zealand plant of this order, the *Metrosideros buxifolia* of Allan Cunningham, is described by that botanist as being a rambling shrub, adhering to trees, and by its lateral roots climbing to the summit of the loftiest timber in the forests of Wangaroa, Bay of Islands, &c."—(*Ibid*.)

"The wood of Myrtleblooms is said by De Candolle to be generally white and compact; but the heavy, hard, dark brown timber which furnishes the South Sea Islanders with their clubs and other weapons is said to come from *Metrosideros polymorpha* or some allied species. The Ake-Ake or *Lignum Vitæ* of New Zealand, the Rata, and *Palmukawa* of the same country, are all hardwooded trees belonging to the genus *Metrosideros*."—(*Ibid*.)

Hursthonse, in his "Britain of the South," says about the Rata (*Metrosideros robusta*)—"There are several varieties of this tree. One grows as fast as a parasite, creeping in numerous stems like ropes up the trunks of the other forest trees, gradually enclosing them till they perish, and then uniting to form a noble tree taller than that which it has destroyed, with an enormous trunk, but hollow within. The leaf and the flower resemble those of the Myrtle, but the flower is of a deep crimson colour with golden stamina. In December and January these giants of the forest give the hillsides a fairy-like appearance from the profusion of this beautiful blossom. The branches are gnarled like those of the Oak; and the trunk also, from its formation, is a series of strange contortions; so that

the wood, being also heavy, close-grained, and very durable, is most valuable to the ship-builder for knees and timbers of all shapes and sizes."

I have just come to a passage in his work which I can hardly reconcile with what I have just quoted above about the flowers of the Rata, in his description of it. He says—"Flora and Pomona have dealt most niggardly with New Zealand. There is no indigenous flower equal to England's Dog Rose—not in combined beauty and fragrance; no indigenous fruit equal to Scotland's Cranberry." I presume we must pardon him. We have now growing in the vicinity of Christchurch thirty-seven varieties of New Zealand Veronicas out of the forty described by Hooker in his "New Zealand Flora." A more beautiful genus than this cannot well belong to any country, both for its diversity in colour of flowers and perpetual evergreen foliage, and I may add to this, almost in flower all the year round.

Ward, in his "Information relative to New Zealand," 1839, writes about the Rata—viz., "This is a fine and useful tree, producing a heavy, close-grained, durable red wood, capable of being turned to almost any purpose of household work, and valuable to the ship-builder, who may find its branches curved to his hand, and requiring but little of the labour of the axe to form it to his purpose. It is found in perfection of all sizes and heights, from 20 to 70 feet high, and from 18 inches to 7 feet in diameter. It prefers a dry stony soil, and varies the pleasantness of its appearance according to the regular or irregular shape of its trunk. Its branches generally shoot from the top of the main stem, and put forth to some height before a leaf appears. The leaves are small, in the shape of the Box, tufted at the top of the tree, forming a crown, and in the distance appear like a cluster of Palms growing out of one large stem, rising far above the parent stock by which they are supported."

Your readers and myself may now form our own conclusions on the various opinions expressed by writers about the Rata of New Zealand.

The Myrtle tribe, most gardeners are well aware, abounds in beautiful plants; and the New Zealand *Metrosideros robusta* is one of these, with its tassels of silken crimson stamens, so remarkable for having no petals, and for the calyx falling off like a lid or extinguisher. This curious calyx is pushed off, not being capable of separating in the usual way; it having all its parts soldered together, as it were, into a hard fleshy lid. When it is time for the stamens to unfold, they push the calyx so forcibly that it breaks away by its base and drops off, leaving the stamens at liberty to expand as fully as may be necessary. The volatile oil contained in the little reservoirs of the bark, the leaves, and the floral envelopes, gives these plants the fragrance which has caused them to be celebrated by poets of all ages.

Enclosed I send you a wild sprig of Rata, I think it is *M. lucida*. Branches of it (in flower) generally arrive in Christchurch about midsummer from the west coast of Canterbury. Passengers by mail coach bring branches with them on account of its beauty when in flower.—WILLIAM SWALE, *Avon-side Botanic Garden, Canterbury, New Zealand.*

EARLY KIDNEY POTATOES.

Lee's Hammersmith Early Kidney.—This new valuable Potato is a great improvement on the old Ashleaf variety, producing more than double the number of tubers at a root, and very large, floury, and white when cooked, and fine in flavour. It has a much better constitution than its parent, as it withstands the disease.

Sandringham Early Kidney is also a very productive variety, coming in about the same time as the above, and yielding about the same quantity at a root, excellent in flavour and floury. It also grows well, being stout in the haulm, and well adapted for that purpose.

I grow the old Ashleaf, Mon's Pride, Lemon Kidney, Albion Kidney, and Bedford Kidney, but none of them comes up to the above two new varieties either in quantity or quality; the latter is valuable for forcing. I have just discovered one tuber diseased (August 5th) among some Albion Kidneys, but I have seen none of the other sorts affected as yet. I grow a border planted late of what remains over of the smallest tubers of each variety for seed, as I find it is a good plan to get them up before they are quite ripe. I mean taking them up immediately, and intend to store them away on shelves lathed and boarded upright so that the air may get under them. There is nothing more done to them until planting-time comes round, merely

looking them over to see if any of them are diseased.—W. MCP., *The Gardens, Snelston Hall, near Ashbourne, Derbyshire.*

ENTOMOLOGICAL SOCIETY'S MEETING.

The last meeting of this Society for the season was held at Burlington House in July, the chair being occupied by H. T. Stainton, Esq., F.R.S., Vice-President. Mr. McLachlan exhibited a remarkable monstrous individual of a species of bee-like flies (Syrphidae), possessing portions of the characters of both sexes, taken at Black Park. Mr. Weir exhibited specimens of the rare moth *Agrotera nemoralis*, taken at Abbot's Wood, near Lewes. Mr. T. Blackmore exhibited an interesting instance of insect-instinct, being specimens of a gall found on Oaks, near Taunton, which had been taken possession of for habitations by a species of ant, *Crematogaster scutellaris*, *Olivier*.

Sir Sidney Saunders communicated a memoir on the habits and economy of certain Hymenopterous insects which nidificate in Briars in Corfu, with notices of the parasitic insects by which they are attacked. The insects themselves were exhibited at the last meeting, and belonged to numerous genera and species of burrowing aculeate Hymenoptera. He also exhibited a specimen of a curious Wasp forming the genus *Raphiglossa*, which he had suffocated with cyanide of potassium whilst asleep, showing the remarkable position of the insect during repose, as described in the paper, the insect affixing itself by its paws to a twig, and extending its body, back downwards, in a horizontal direction. Mr. Butler read a list of the species of Galeodidae, insects allied to the Scorpions, with descriptions of new species in the British Museum.

STONE FRUITS AND HARD SOIL.

It has often occurred to me, while observing the fruit trees growing on the walls of houses in many of the villages throughout England, especially in the southern districts, that the firmness of the soil has much to do with the longevity, hardiness, and fruitfulness of these trees, which are generally loaded with fruit of very fair quality. There is little attention given in the way of cultivation; all the training they get is a cut here and there to prevent the young branches from pulling the old ones from their fastening. They must have grown apæe at some period, as large breadths of mason-work are covered with single trees, such as are not met with in many gardens. In this locality (Oxford), Apricots have been famous for many years, and great crops have been gathered; and the industrious villagers have often been able to pay their rents from the old trees on the ends of their houses. It has appeared to me in most cases that these veterans have been planted with very little care—probably a hole has been made, enough to twist the roots into, and the soil replaced over them, and rammed down as if to form part of a floor. The hard-trodden gravel (in many cases easeway and pavement), would lead one to suppose that moisture could never reach the fibres, but I suppose the fibres must travel to the moisture; a wide street is generally the space where the border should be. Other trees have the usual outhouses standing over the space where the roots are supposed to find their food. It is evident there must be food, or where is such fine foliage and luscious fruit manufactured? Vines are met with often growing under the same circumstances: one on a tradesman's house in a town not far from here is something wonderful in its way—the kind is the black Esperione. I am told that it has produced heavy crops for many years past, and this year the bunches almost touch one another. There are only a few inches of open space between the pavement and base of the house front wall. The pavement and causeway together, between the Vine and the street, may be 12 feet wide, yet this Vine luxuriates, and supplies its owner with plenty of fruit, which is used generally for wine-making. Without discussing the matter further, is there anything we can learn from these trees, which are more productive, of stronger constitution, and less liable to disease than the finest-trained trees under the care of some of our most distinguished gardeners? From experience, I believe that the firmness of the soil prevents over-luxuriant growth, inducing the roots to become a mass of healthy fibre, instead of their sending out large soft feeders, drawing up large quantities of water, which remains in the branches till the short dark days of winter. No fruit-buds are matured; the buds start early into growth long before they are safe from frost; the sap, which has been flowing freely, receives a check; nothing is seen at the time, but before summer has advanced very far, a large limb (perhaps the headliest-looking in the tree), dies-off suddenly; it is cut out, other branches die-off in the same

way, and the poor tree is sadly deformed. Cases similar to this are met with all over the country, and yet we have found no preventive.

One thing I would suggest to young planters is,—never accept a tree which has been often cut back in the nursery, or one which has not been properly cut. When pieces have been left, the branches are always liable to die-back where these pieces have been attached. When the cut is clean and properly done, the bark will grow over, and the wound will heal-up nicely. When planting is done, never use manure (except for mulching, to keep out frost or drought); let all the soil, after it has been prepared, be made as firm as a rammer can make it,—if stones are plentiful, so much the better; the soil may be placed over the roots, and made only moderately firm. Endeavour to get the tree to start freely, and use the knife only where it cannot be avoided. When the roots have run a little, they will come in contact with the hard-rammed soil, and will throw out fibre in all directions, which will cause the tree to grow sturdy, and the young wood will become very hard. When any shoot takes the lead, and is likely to monopolise the whole growth, take off a joint or two at top, and a number of small shoots will spring up; train them over the empty space, and the foundation of a sound tree will be formed. Avoid the use of the knife in winter if possible, and if root-pruning should become necessary, let it be done early in the autumn,—but examine the roots first at one side, taking off none except they may be going downwards, or away from heat and air,—replace the soil, or fresh loam instead, and ram it as hard as possible under the roots, and lay every fibre carefully in its place, and cover them over as before. A very small portion of the tree thus treated will be enough to check unnecessary growth, and large firm leaves, plenty of natural fruit-spurs, and a hardy tree, will be the reward. The cutting round the whole tree with a spade, as some have done, is reckless and mischievous in the extreme.

If too rich soil should be the cause of watery growth, lift the tree and mix some lime rubbish in the earth; ram it down, and lay-out the roots over it, and place 6 inches of loam over them. This should be done as the leaves are about to fall in autumn.

Speaking of the Vine, how often do we see promising young rods bear well for a few years, their roots filling the porous border. They begin to fall off: extra top-dressing is given, shanking goes on, red spider destroys the foliage; yet all seems right at the roots. But careful examination will show that the feeders have found their way into a poor unhealthy subsoil, and as fast as fresh rootlets are made they die. The fine rich border is left behind, and all the manuring, watering, &c., is so much labour thrown away. The points of the roots are beyond help, so the vine by degrees becomes a wreck. But if Asparagus beds, or a free sound loam, is in the way of the roots, instead of unhealthy stuff, the Vines will not only remain healthy and vigorous, but be rejuvenated. The same applies to all trees, even to the Oak of the forest: a tree may grow luxuriantly for years, and at last begin to fail—hundreds around me are striking examples. If the cause was searched after, the active roots would be found far from the trunk, out of the reach of the famous loam which had made the gigantic tree, and struggling for an existence among material foreign to their nature. We should never despise the lessons which old trees in cottagers' gardens teach us, but search out the cause of their success, and it will be found that the roots are in their natural element; and the roots of our own trees, which are growing at railway speed, are in unusually rich quarters, where they will luxuriate till they bring about their own destruction.—M. TEMPLE (in *The Gardener*).

A GRUMBLE ABOUT ROSES.

At a time when so much has been said and done about Roses it may appear something like heresy to put in a plea of discontent at the limited area which the Rose-growers of the present day seem to move in. I confess making this charge with considerable diffidence, especially as I do not pretend to be well-up in this queen of flowers, and am therefore liable to run into error, perhaps, in some of the views I take on the matter. These may be summed-up into a single complaint against Rose-growers, as a whole, of running too much in a groove—so much so that, although great improvements doubtless have been made in many varieties, there were as many really distinct forms in cultivation fifty years ago as now, and the colours then to be had have not been multiplied since.

For instance, the old Tusean Rose presented as dark a tint of a rich plum colour as the best kinds to be seen in ordinary stands at flower shows. The old white Rose was quite as sweet as more recent ones; and if the old Moss has been improved in some of its properties, it is not all other varieties that can beat the old one. The Yellow Banksian and Macartney seem to be ignored altogether by the leading Rose-growers of the present day, and assuredly something more might have been done with the latter two. The very praiseworthy efforts of those who provide us with new varieties have been mostly directed towards improving the size or shape of individual flowers of the kinds that bloom in greatest abundance in June. This is all very well, and great credit is due to them for this; but there is no reason why other kinds should be neglected, and also why improvement should not take another form. The old York-and-Lancaster Rose, which now and then occurs in old places, carries a charm with it which the new-fashioned varieties with their unpronounceable French names fail to do; for although it may not compete with the latter in point of form, the fact of its being striped gives it an importance which a mere multiplicity of petals all of one hue would fail to do. And who can blame the admirer of a striped Rose, when in all probability it is a greater rarity than many that first made their appearance in 1872? But why should not the old York-and-Lancaster have its place amongst others of its family? Why has it not been improved, and why are Roses equalling it in the regularity of its markings not forthcoming at our Rose shows, with all the improvements which a greater number of petals and a better form can give?

Florists assume to accomplish, or rather to approach very near to, any standard of excellence that may be laid down. Why, then, do they not furnish us with a good striped Rose having less tendency to run into self colours than the York-and-Lancaster Rose? There are many persons not yet educated to discern at a glance the small difference there is in colour between many of the excellent stands of Roses that are exhibited for competition, but who would be delighted were a good striped Rose to make its appearance amongst them; and I am not sure that a meritorious single variety might not be acceptable now and then—not in an exhibition stand, perhaps, but in a Rose bed or border. Single flowers of many kinds are not always to be despised. I remember many years ago having a very pretty single Dahlia for some time, but I lost it. I certainly do not remember any single Rose of dwarf growth possessed of much merit, but that is no reason why there should not be one. Moreover, might I ask hybridisers if nothing more can be made of the Yellow Banksian? Can its beautiful flowers not be had later in the season than they now are? and if some of their qualities cannot be transferred to another variety? also if the Macartney Rose cannot be made to conform to the wants of the present day? and lastly, if hybridising the Persian Yellow with the so-called Hybrid Perpetual class cannot be accomplished, so as to give us that inimitable colour which even Maréchal Niel in all his glory cannot supply?

Other complaints I have, but I fear I have said enough to call down the indignation of the queen of flowers, and in a greater degree that of many of her votaries; but if what I have said be the means of directing attention to improvements hitherto neglected, I can willingly submit to any amount of chastisement to which a grumbler at existing things may be exposed. Certainly, in the matter of Roses it would be better, instead of quibbling over the respective merits of new varieties that may or may not differ from older ones, that some one should start on new ground altogether. Enough has been said to show to Rose-growers that, although they are entitled to our best thanks for what they have done, they have pursued one course long enough now to satisfy those outside the fold, and that hereafter it would be better if they took other ground.—J. ROBSON.

GARDENING IN THE WEST.—No. 6.

BECKETT PARK, THE SEAT OF VISCOUNT BARRINGTON, M.P.

It is a quaint old town that of Shrivvenham, in which thatched cottages appear to outnumber those covered with slates and tiles, and rather picturesque; and at no great distance from it and the station on the Great-Western main line is Beckett Park, which forms the subject of our present notice. Leading to it from the village of Shrivvenham—for it is nothing more—we pursue a pleasant country road till the park gates are reached, respecting which we have nothing special to re-

mark, save that for years they have been freely thrown open on the occasion of what is well known in the district as the Great-Western Fête, when the hundreds of workmen engaged at the Swindon Railway Works, with their families, and many more of the *employés* besides, have, through the liberality of the proprietor, been enabled to make it their trysting-place.

The mansion, of which we give a view from a photograph by Mr. Wilkinson, of Trowbridge, is stone-built and of modern construction, with an ample carriage square in front of the principal entrance, which faces the east. It is surrounded with seventeen acres of lawn dotted with choice trees and shrubs, and close to it is a lake crossed by several bridges, one of which is represented in our engraving. The lake has no great breadth in any part, except where it divides into two branches, forming a large island; but along its shores are picturesque walks more

than a mile in length. Indeed the walks about the place are its great charm. There are some four miles of walks, much of them confined between Box hedges 3 feet high, and which had been much higher but are now clipped down, and which, it is stated, were planted by Bishop Beckett. These walks are always shady and cool, and are kept in admirable order. On the west side of the house is a terrace wall covered with Roses and Magnolias, having standard Roses surrounded with Mignonette, and flower beds in front. This is a veritable garden of sweet odours in the evening; and behind it again we have *Félicité* Perpetuée Rose hanging in loose but profuse clusters of white blossoms, accompanied with brilliant Gladioluses and Geraniums. The flower garden is on the same side of the mansion; it is neatly laid out and effectively planted, especially the oblong centre, which has at the outside two rows of Eche-

BECKETT HOUSE.

veria secunda glauca, one on a ramp and the other on the flat, and the space within is filled up with *Alternanthera spathulata* and Golden Feather *Pyrethrum*, while the raised centre consists of *Echeverias* and *Alternanthera magnifica*. The outer beds are edged with *Cerastium tomentosum*, within which are planted in succession, according to the side, Blue Bonnet or Purple King *Verbena*, Flower of Spring or Bijou *Geranium*, the old Tom Thumb scarlet, and *Aurea-Floribunda Calceolaria*. Altogether from 20,000 to 30,000 plants, we are informed, are yearly required for this garden. There is also a conservatory on the same side of the house, kept in good order, and containing scarlet *Geraniums* and *Heliotropes* extending from floor to roof on the pillars and back wall, together with *Tacsonia mollissima*, *Canellias*, *Dicksonias* and other Ferns.

We have before alluded to the walks as being one of the

most agreeable features of the place; in particular we would notice an avenue with Beech and Oak on each side, along with Yews, Box, and mixed shrubs; a walk from the terrace to the church with a Yew hedge on each side; and in front of where the old mansion stood we have clumps of Oaks and Elms, forming an avenue through which Uffington church is seen in the distance. From the same side of the park White Horse Hill is plainly seen, though the figure of the horse, whatever its origin, is now by no means clear; still, the scenery is pretty in all directions, and the park is well studded with trees. We noticed an Oak 15 feet in circumference of stem, Beeches with 50 feet of clean stem, several fine Scotch Firs, and of other Conifers handsome trees of the Deciduous Cypress, *Pinus Cembra*, *Picea Picea*, and Silver Fir.

The fruit and kitchen garden is about four acres in extent,

of an irregular form, which will be most readily described as a triangle, with its base to the north and its apex to the south cut off; there is consequently a good length of wall having a south aspect. A length of 140 feet is covered with a Peach case 7 feet wide, 10 feet high at back, and well provided with the means of ventilation by sashes opening outwards in front and upwards at back. In front of this are frames and pits filled with Balsams, Pelargoniums for late bloom, Chinese Primulas, Cinerarias, &c., and which are also used for bedding plants and general purposes. In front of the pits again is a range of houses used for growing Fuchsias, forcing Roses, Strawberries, &c.; and there is besides a range of span-roofed houses 87 feet long in three divisions, in which are grown Orchids, Pelargoniums of all sections largely, various other plants, and Cucumbers. The vinerias are only two in number, 28 feet long by 16 feet wide. The earlier contained a splendid crop of Black Hamburgh and excellent Muscats. The bunches colouring in the later house also promised to be fine.

On the walls Apricots were scanty, Morello Cherries abundant, Passe Colmar Pear on the west wall an excellent crop, but other kinds not so productive. Dwarf Apple trees were also bearing freely, though the soil is by no means favourable to fruit trees, as at 18 inches from the surface there is a ferruginous sand, which soon kills the trees when the roots reach it.

In the open quarters of the kitchen garden, which slopes rapidly to the south, Globe Artichokes are grown in unusual plenty, and it is worthy of remark that the Asparagus beds are double the distance apart that we commonly find. This has arisen from Mr. Smith, the gardener, having used the roots in each alternate bed for forcing, and the result was that he has had more and finer produce from those left than from double the number of beds placed closer together. All the other crops were in excellent condition, and the neatness and order throughout were highly creditable to Mr. Smith's management.

ON THE URARI,

THE DEADLY ARROW-POISON OF THE INDIAN TRIBES IN BRITISH GUIANA.

[Read by Dr. R. Schomburgk before the Adelaide Philosophical Society, on April 10th, 1866.]

(Continued from page 63.)

During my brother's stay among these tribes he convinced himself that, as main ingredients for the preparation of the poison, they used either the bark of *Rouhamon guianensis* or *Strychnos cogens*. Though their poison is similar to that of the urari of the Macusis, as far as colour and consistency is concerned, yet, as I mentioned before, it is a great deal inferior in respect to strength. When my brother showed the Guianans and Maiongkongs some dried specimens of *Strychnos toxifera*, which he had in his herbarium, it seemed to be quite unknown to them; but when he showed them the specimens of *Rouhamon* and *Strychnos cogens* they immediately recognised in it the plants used by them for the preparation of their arrow-poison. In British Guiana the preparation of the urari is known only to a few tribes. Von Martins, who says the same of the tribes of Brazil, states as a cause that those plants which contribute mostly to the preparation of the deadly extract certainly appear sporadical, which is the cause that the preparation of the urari is only known to certain tribes where the plants grow. As far as the inhabitants of Guiana are concerned, this statement would not prove correct, as I have found not only the *Strychnos toxifera* on the river Pomeroon, but also another kind of *Strychnos* on the Barama and Waini, a territory which is inhabited by the tribes of Warraus, Caribees, and Arawaks, which tribes do not use the arrow-poison, nor do they know anything of the properties of the plant. In British Guiana only those tribes which carry the blow-pipe for a weapon know the use of the urari. During my brother's stay in Pirara, in 1837, he was as little successful in being present at the preparation of the poison. Leaving the village he asked Mr. Youd, the missionary, to try to persuade the preparer of poison in the Canuku Mountains to boil the urari in his presence, and communicate to him the process. Mr. Youd was successful in persuading the poison-preparer to boil the poison in Pirara, in a hut erected for the purpose in front of the missionary's house, which enabled Mr. Youd to watch the process. My brother was again successful in witnessing the preparation of the urari on his third visit to Pirara. The experience gathered by these witnesses agrees in every respect with that obtained by myself, which may have its cause by our seeing the preparation made by the same individual.

I now make my own observations. I found at the Canuku Mountains the same renowned urari preparer who served my brother as a guide to the regions of the Urari plants, whom I engaged also as my guide, and under the same difficulties we reached the plants, which to my great disappointment showed neither flower nor fruit. We collected a great quantity of bark of the plants, as the Indian had promised to prepare, after our return to the village, the urari in my presence. To my great consternation the old poison-boiler tried to evade his given promise, when I reminded him of it the next morning, with all kinds of excuses—pretending to be sick, complaining of headache, and wishing to put off the boiling for some days. The cunning Indian knew too well from experience that such pretended refusal would secure him the greater reward, and to gain my purpose I had to add to the reward already promised some more powder and knives. At last my long-cherished wish to witness the preparation of the urari, of which so many fables have been told (as there always will be about anything enveloped in a certain mystery), was to be fulfilled, and I found the process, except a few unimportant ceremonies, as simple as possible. The small hut, which on my arrival in the village I supposed to be the laboratory of the chemist, was really the Urari house. The Indian began first to take the bark from the *Strychnos* which we had brought from the Flamikipang, then produced the other ingredients which it seemed he had in store, and separated the required quantities. I am sorry to say that from the barks to be used besides the *Strychnos*, I could not ascertain the botanical names of these plants, which he called Tarireng, Wakarimo, and Tararemu; but to all appearances they also belonged to a species of *Strychnos*. When I asked him where they grew, he answered, far, far away in the mountains; it would take him five days to go there. The preparation of the several ingredients would be according to the weight, as follows:—Bark of *Strychnos toxifera*, 2 lbs.; from Yakki (*Strychnos Schomburgkii*), $\frac{1}{4}$ lb.; Arimaru (*Strychnos cogens*), $\frac{1}{4}$ lb.; Wakarimo, $\frac{1}{4}$ lb.; the root of Tarireng, $\frac{1}{2}$ oz.; the root of Tararemu, $\frac{1}{2}$ ounce; the fleshy root of Muramu (*Cissus spec.*); four small pieces of wood of a tree of the species of *Xanthoxylea** called Manuca.

Having finished the preparations, he went to his hut and returned with a new earthen pot holding about four quarts, and two smaller ones, also quite new, formed like a flat pan. He went into the Urari house and put down the vessels. In the first the poison was to be boiled, in the others it was to be exposed to the sun for condensation. The great strainer or funnel, made out of Palm leaves, was cleaned, and fresh silk-grass put into it to strain the fluid; the great block of wood dug into the ground to serve as a mortar, was cleaned, and in it the several ingredients were crushed. The urari preparer, after having arranged everything, built a hearth with three stones and laid the wood ready to light the fire, and went away to fetch (as I was informed afterwards, for I had not exchanged a single word with the preparer of the poison, and got all the information from my companions) the utensils to light the fire, though there was a large fire burning close by us, but which was of no use, being lighted by profane hands. Neither dare he use any water except it be brought in the pot to be used for the operation, as in fact no other implement must be used but such as has been made by the cook; neither must he have any assistance from any of the inhabitants. Any transgression of the sacred rules would nullify the operation of the poison. In addition to the fleshy root of the Muramu, he crushed the several different kinds of bark, but every one singly, in the mortar, lighted the carefully piled-up wood, and then threw first into the pot—which holds about seven quarts, and which was filled with water—the bark of the *Strychnos toxifera*. As soon as the water began to boil the Indian added at certain intervals a handful of the other ingredients except the Muramu root. In doing so he bent his head over the pot, strongly blowing into the mixture, which he said afterwards was adding considerably to the strength of the poison. During the process he only kept so much fire as was necessary for a slow boiling, carefully skimming the foam collecting on the extract. Within the next twenty-four hours the old man left the fire only for one moment—keeping up the fire at an equal heat. After the lapse of twenty-four hours the extract became thick, and was lessened by the boiling to about a quart, and had assumed the colour of a strong decoction of coffee. The old cook then took the extract from the fire, and poured it in

* Manuca is the strong bitter wood of a tree of the *Xanthoxylea*. The bark and the root are used as an effective remedy against syphilitic sickness on the Rio Negro, Amazon, and Rio Branco.

to the strainer above mentioned; the extract trickling slowly into another flat vessel, left the remainder in the silk grass. After exposing the strained extract to the sun for about three hours, he added the slimy juice pressed out of the root of Muramu which had previously been soaked for a short time in the boiling poison, and then had been pressed out. The poison presented immediately a remarkable alteration, curdling to a jelly-like substance. After this peculiar process, he poured the poison into earthen vessels, blatter than the ones before mentioned, for the purpose of changing the poison to a consistence equal to that of thick treacle by exposing it to the sun. Afterwards the poison was poured into the peculiar small calabashes or small half-round earthen vessels, manufactured only for that purpose, where it will ultimately change to a hard substance.

The third day the poison was ready; when the cook, satisfied with the produce, tried the strength of the poison in my presence, for which purpose he caught some lizards. He dipped the point of a pin which I gave him into the black treacle-like substance, let the poison get dry, and wounded one of the lizards in one of the toes of the hind foot, and then let it run. After the lapse of nine minutes the peculiar symptoms of the poison made their appearance, and one minute after that the slightly wounded animal was dead. A second and third were wounded on the tails, when the poison operated in the same time. He had chosen the lizards for the trial, maintaining that the operation of the urari with a warm-blooded animal takes only half the time which is required for a cold-blooded animal. A rat caught by a boy confirmed that assertion, and died in the fourth minute; a fox, which I had bought for my dinner, died the third minute. Each of these animals was but slightly wounded. The Indians maintain that the poison, even if kept well, and especially dry, will retain its life-destroying power only two years. Should the poison lose its power, they restore it by adding a little juice of the poisonous Manihot root (Manihot utilisima). After pouring some of the Manihot juice into a calabash containing the urari, they dig it into the ground, covering it with earth, and let it remain there for a day and a half. The Manihot juice is then mixed with the poison, and it then regains its former strength. The truth that after a certain lapse of time the poison would need a longer time to take effect, I have seen confirmed by my own experience with the urari manufactured in my presence. I brought some of the urari with me to Berlin, and made several experiments with it, when I found that it frequently took from fifteen to twenty minutes, according to the tenacity of life, before death took place. I am sorry to say that as yet a really correct analysis of the poison has not been made, though the renowned chemist, Professor Heintz, of Berlin, has spent a long time to ascertain it.

A LUNAR RAINBOW.—At 9.20 P.M. on August 4th the moon was nearly due south, and appeared unusually large and bright, and the clouds in the north looked wild and black, when to my great delight I saw a portion of a rainbow, and in a few minutes it became quite perfect, forming a semicircle. The colours were not so bright as if caused by the sun. This is the first time that I ever saw a lunar rainbow.—JAMES R. POCOCK, *Brombrough Hall Garden, Che. hire.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

As the rains are very partial, it is still necessary in many localities to continue watering seed beds and recently-transplanted crops. Keep the soil loose where practicable; give timely thinnings to those crops that require it, and water afterwards if the soil is dry. The latest crops of *Brussels* should now be planted out if not yet done. Another sowing of *Cabbage* may be made about the end of the week to stand in the seed-bed through the winter. A late sowing sometimes comes in very useful; also make a sowing of Red Dutch for summer use. Make a sowing of *Campanulas* in the end of the week for plants to stand the winter. The *A. italic* is a large and excellent sort for this purpose. Previous to earthing-up *Cherry* for the first time, give the trenches a thorough watering, as the plants will not receive much benefit by the application afterwards. The earthing-up should be carefully done, the whole of the leaves being kept close together at the time. The lights may be drawn off these *Cucumbers* that are in frames during gentle showers of rain, but not when it is sufficiently heavy to injure the leaves. Gather *Gherkins* for pickling. Keep the crop of *Downy Kidney Beans* closely gathered, for if allowed to remain

until they are too old for use they do not bear as they otherwise would. Sow largely of *Lettuce* for standing through the winter. The Brown Cos, Black-seeded Bath Cos, Green Cos, and Hardy Hammersmith or Brown Cos are the best sorts for sowing at this season. Plant-out from the late sowings for autumn use. Pull-up the *Onions*, and those that have done growing. If the main crops have long necks the tops may be broken down; if not, there is no advantage in doing so. Make another sowing of Black and White Spanish *Radishes*, and also of the Turnip-rooted sorts. Let the forwardest of the *Tomatoes* be fully exposed to the sun, remove some of the leaves which shade the fruit. Keep all the shoots stopped as soon as there is sufficient young fruit on the plants.

FRUIT GARDEN.

Vines will now require much attention where there is a prospect of ripening the fruit. The bunches should receive the final thinning, and unless in the case of small sorts, no more than one bunch should be left on a shoot. Remove all superfluous wood in order to throw as much strength as possible into the fruit. If the spur-system of pruning is adopted leave as many shoots besides those in fruit as will be wanted next season; shorten bearing shoots one joint beyond the bunch, or to the joint of the fruit provided the leader is preserved and one joint of the lateral allowed to remain. Pick-out a few of the buds at the axils of the leaves towards the points of these shoots, that the buds at their base may be rendered more plump for next season. If the long or succession-rod system is followed, no short shoots should be left that do not carry fruit, and these must be kept well shortened, so that by removing all useless growth and plucking-out the young buds in the axils of the leaves of such shoots, more strength and free exposure may be given to the long shoots you intend for bearing next year. Leaving a lateral with a leaf or two attached has a tendency to strengthen the bud at the base, and prevents the bud bursting if the shoot should be rather prematurely shortened; but some successful gardeners object altogether to the leaving of such laterals, considering that they render the buds three-cornered instead of plump and round. Grafts should now have their bandages loosened and their shoots properly secured from wind. See that mildew does not make its appearance on your wall trees. As a temporary remedy nothing is preferable to flowers of sulphur; if merely the points of the shoots become affected cut them off at once. Some trees from their tender nature are very liable to its attacks, but in their case its ravages may be much modified if not altogether removed by paying attention to keeping the roots and top of the tree in an equal state as respects temperature and moisture.

FLOWER GARDEN.

In addition to the proper preparation of the soil of flower-beds it will also in another season be advisable to place more reliance upon annuals for an early spring display, and, consequently, a proper preparation must be made by sowing a general collection of the best kinds towards the middle of September. In the spring the planting of the beds is recommended to be thicker than usual, and accordingly, instead of allowing one plant to every square foot, as was the rule in former years, two are planted. Flower gardens will now be in their greatest beauty, and every means must be taken to keep turf, gravel, and edgings of all kinds in the neatest possible order, that no drawbacks to the complete keeping of the whole may occur. Dead flowers should be picked off daily, and stray growths reduced within proper limits. Trailing and climbing plants should be frequently gone over to keep them neatly trained and secure from rough winds. For the same purpose examine *Hollyhocks*, *Dahlia*s, and other tall-growing plants. Remove dead flowers from *Roses*, and encourage the production of autumn blooms in the *Perpetuals* by watering with liquid manure; and mulching the surface of the ground where practicable. Commence the propagation of plants for next season, in which dispatch with the more delicate *Pelargoniums* should be urged to get them established before winter. Fork ground among *Dahlia*s slightly, and mulch the surface with very rotten manure; water plentifully every evening. When the weather is dry take care that the laterals are well staked out, and use every means to entrap earwigs and other vermin which injure the flowers. Look over faded blooms of *Pinks*, extracting the petals from the pods. Should wet set in the decayed petals will act prejudicially by retaining moisture round the lower part, which will cause rotteness, and consequent destruction. Rooted cuttings of *Pansies* for making up autumnal beds should now be ready, or nearly so. It will, therefore, be necessary to make beds for their reception. In doing so it is absolutely necessary that wireworms should be caught, therefore the compost should have repeated turnings, for those pests are as destructive to young *Pansies* as they are to *Carnation* layers. Throw out the soil from the *Tulip* bed on to the paths, so that it may sweeten previously to being returned. Some florists adopt with considerable success the plan of sowing on it *Mustard* seed, which after having vegetated is mixed with the soil; this is believed to be the means of banishing wireworms from the bed.

GREENHOUSE AND CONSERVATORY.

In order to maintain a certain amount of gaiety in the conservatory a stock of succession plants must necessarily be kept up; any plants, therefore, in pots which it is desirable should be grown quickly may now have a shift. It will not, however, be advisable to give them a large shift at this season, as what ever wood the plant makes up to the present shift must be ripened, with perhaps the exception of such free-flowering plants as bloom on the growing wood. As this shift will have to carry the plant through the winter months the drainage of the pots should be ample: when established, a free open situation should be selected for the newly-potted plants, in order that any fresh growth made may be ripened. Where valuable tender plants are out of doors care must be taken to keep heavy rains off them, and if the weather should become dull and wet no time should be lost in removing them under cover of glass.

PITS AND FRAMES.

Proceed with the propagation of all bedding-out plants as expeditiously as possible, making choice of the more difficult ones first, such as Nierembergias, Lotuses, and the like. Leschenaultias for turning out next season should now be strong plants; give them another shift if they require it. Propagate scarlet, variegated, and common Pelargoniums as fast as you can get cuttings.—W. KEANE.

DOINGS OF THE LAST WEEK.

We have been favoured with a good shower of rain, which will greatly assist our drooping flowers. It was entirely local in its extent, as our next neighbour had scarcely a drop, and kept his men at work watering all day, and yet when our rainfall was gauged there was 0.68 inch. The rain was from passing thunder showers, and these are generally local.

FRUIT AND KITCHEN GARDEN.

We took advantage of the rainfall to get out all green crops. We have tried in all manner of ways, and in different parts of the garden to grow Broccoli, and have now given it up. We planted out Sprouting Broccoli after the Early Potatoes; our ground is generally in good condition, and we do not care to dig it in any way for this crop. We filled up any odd corners with Coleworts, which come in very useful during the autumn months.

We have a plentiful supply of Peas, Dwarf Kidney Beans, and Scarlet Runners. In passing we would again invite attention to the new Peas which have been recently introduced to the public. That standard variety Veitch's Perfection is fully equalled, if not surpassed, by Carter's G. F. Wilson. It is earlier than Perfection, the pods are, perhaps, larger, it bears abundantly, and the flavour is all that can be desired in a Marrow Pea. Laxton's Omega is truly named; it is the latest Pea, and very distinct in character. It is also a Marrow Pea of about the same height as G. F. Wilson, 2½ feet, and an abundant bearer; the pods and peas are of the deepest green. Our latest crop is looking remarkably well, and has been much benefited by the rains. We recommend the ground intended for the latest crop of Peas not to be cropped previously, and the best preparation is to hoe the ground over just before drawing the drills; the seed should also be trodden in quite finely.

Celery has not succeeded well with us this year; much of the earliest bolted, and the later sowing, although carefully attended to, does not seem to grow freely.

We have planted out nearly all our *Strawberry plants*. If a full crop is desired next year no time should be lost in getting the plants out, and if the ground is not ready for them, as is the case with some of our own, the plants should be shifted into 5-inch pots in some rich compost, where they will grow immensely in three or four weeks. Should any trace of red spider be found on the leaves, do not fail to dip the plants as recommended last week.

Early Apples and Pears.—The best are now abundant, and make a useful auxiliary for the dessert. Doyenné d'Été Pear is over, but Jargonelle is now in, and Devonshire Quarrenden Apple has a fine appearance on the table when dished up neatly.

We have no ground in the kitchen garden long unoccupied at this time; all spare ground is either hoed over and planted with green crops, or manured and dug to be planted. Even if the ground is not required, it should be dug over, or at least cleared of weeds, and left in a tidy condition.

FRUIT AND FORCING HOUSES.

Pine Apples.—This is just the weather for maturing the Pine plants required for fruiting in the spring. The pots are now well filled with roots, and the plants have made sturdy growth. The house is aired freely in the day and a little air is left on all night; while the weather continues so warm no artificial heat is applied. We are also careful in regard to watering. The Pine Apple does not require much water, and when we used to fruit the plants in 13 and 15-inch pots, once a week was sufficient, but since we have learned to fruit the Queens in 9 and 10 inch pots, and such strong-growing sorts as Charlotte Rothschild in 12-inch, as a matter of course they require more water.

We keep the succession houses shut-up closely at night, nor do we give air so freely in the daytime, and water is kept continually in the evaporating-troughs.

Vineries.—In the early houses, especially the Early Muscat house, the leaves have suffered much from the recent hot sunshine—it seemed quite to crumple them up. We like to see the foliage remain on the Vines later than this, but the wood is well ripened, and the buds are very prominent. The borders have had a good soaking of water, which will keep the roots in a healthy state. In the late houses all the varieties are approaching to ripeness, and promise to colour better than usual. We cannot say why, but in the earliest houses our Grapes are seldom surpassed for flavour and colour, and in the late houses the flavour is as good, but the Grapes seldom colour well. We looked over the houses, pinched-back the few lateral shoots that were growing, and secured all heavy bunches to the wires with a strong strand of bast. Through want of attention to properly securing the shoots to the wires, we have seen bunches break the fastening which attached the branch to the wire, and its falling weight snapped the branch quite off. We do not keep a too dry atmosphere in the vineries when the Grapes are ripening. Many, even professional gardeners, will not allow a drop of water to be sprinkled on borders or paths, and watering a few plants in the house is even considered objectionable. Bear in mind that a moderately moist atmosphere even when the Grapes are coloring is beneficial to the Vines, and it also improves the quality of the Grapes. Another matter worth noticing is this: Many persons have a notion that it is necessary to expose the bunches to the sun in order to finish them off well. In the case of white Grapes, when they are nearly ripe, exposing the bunches to the sun causes them to finish-off a golden colour, especially Muscat of Alexandria and allied varieties; Black Hamburgh, on the other hand, does best if the bunches are shaded by the leaves. Only this morning we looked into a smallinery belonging to an amateur; the house is planted with Black Hamburgh; and what was our surprise to see that a number of leaves had been broken off and were lying on the ground. On inquiring the reason we were told it was to allow the sun to get at the bunches. Now, we can freely say our friend has very much injured his Vines, as they are carrying a very heavy crop, and every leaf was necessary to the health of the Vines, besides which, exposing the bunches to the sun at the time when the berries had just finished stoning, was a very rash proceeding, to say the least of it.

ORCHARD HOUSE.

The fruit is now ripening, and we shall have a continuous supply of fruit until the end of October from the Peach and Nectarine trees; these are making a very vigorous growth. We have just looked over the trees for the last time, and have pinched all gross shoots well back; but in doing this care was observed to cut back to a leaf that had two small leaves at its base. If the weak wood is stopped back in August, probably all the buds will be flower buds, and there will be no leader, so that the shoot will die back during the ensuing summer. On many of the trees the wood was so much crowded that it was necessary to thin-out much of it in order to expose what remained to the air and light. We finished picking the Early York Peach on Saturday. The same day Lord Napier Nectarine came in; this is one of the seedlings raised by Mr. T. Rivers, and will doubtless be an acquisition; it ripened this year with Hunt's Tawny, and is far superior to that variety in flavour, and is not so much subject to mildew. The true variety of Early Grosse Mignonne is a noble fruit, and nearly as early as Early York. Some of the Plums are also giving good fruit. Angelina Burdett is ripe, and is a well-flavoured purple Plum. A variety of Green Gage, which we call Early Gage, has also supplied us with very fine fruit.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Louis Van Houtte, Royal Nurseries, Ghent.—*Catalogue of Bulbs and other Flowers, Roots, &c.*
Joseph Vervaene & Co., Boulevard Lonsbergs, 42, Ghent.—*Prix Courant pour 1873-74.*

TO CORRESPONDENTS.

* * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Contry Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

BOOKS (*J. S. T.*).—"British Ferns" by G. W. Johnson, which may be had for 3s. 6d., or post free from our office for 3s. 9d.

PEARS DISEASED (*L. J. K.*).—The state in which your Pears are caused by the rot-pruning of last year. The roots have not yet got into sufficient soil to nourish the tree, and this, coupled with the recent dry weather, has produced the result. We cannot make out the insect.

ADDRESS (*Billinghugh*).—"English Mechanic," Tavistock Street, Covent Garden, London, W.C.

PANSIES (*Millyan & Kerr*).—Unfortunately they were too withered to pass an opinion upon them.

LIQUID TO DESTROY WEEDS (*J. Lock*).—It was boiling brine.

APRICOT TREES SHEDDING THEIR LEAVES (*C. B. Livingston*).—We cannot account for this in any way, except that the trees are suffering from want of water at the roots. Will you ascertain it is the cause, and let us know?

AGRICULTURE OF KENT.—We have received a letter from Mr. Witherspoon in defence of his own remarks on this subject, the justice of which has since been contested by "D. Deal." Without ranking ourselves as supporters of the opinions of the one or the other, we have suddenly been involved in a war of north and south; and as peacemakers are ever blessed, we hope here to put an end to the distant sounds of war. Mr. Witherspoon criticised rather sharply, but honestly, the agriculture of that portion of the county through which he passed on his *Glabolus* hunt; and "D. Deal," as a "man of Kent," stood forth boldly and on the moment, as the men of his county are wont to do, in defence. We shall merely insert the concluding words of Mr. Witherspoon's letter, for their spirit is so good—"I am glad my impressions of Kent were formed from its poorer districts; and after all, your readers may possibly credit me with doing justice as far as possible from observation. On the whole I read with interest 'D. Deal's' contributions; and let me assure him my strictures were written with an eye to good, and not to unnecessarily do injustice to the county of Kent, which I still think—as seen—as regards success is foolishly attempting the impossible, by competing with inferior against immeasurably superior machinery.—JOSEPH WITHERSPOON."

TWIN CUCUMBERS (*B. Williams*).—Such eccentricities are not uncommon.

BRANCHES OF PLUM DYING (*W. G. D.*).—The cause of the branches of your Plum dying off is from some injury they have received, and this most probably is due to frost. This injury may have happened long ago, and perhaps in some previous autumn when the tree was full of sap, and a sudden and severe frost has come and lacerated the sap vessels. It is long sometimes before the injury is apparent, as in your case, and at others it is immediate. There is no remedy.

PEACH TREE PRESERVING (*A Subscriber*).—The best way is to advertise his cure, and as he agrees not to be paid unless a cure is effected there will be no reason to complain. If it is successful, that result will be his best recommendation.

HOLLIES (*Aberdonensis*).—We cannot imagine what is the matter with your green Hollies, seeing that all the others in the same soil are doing well. The cause of the Apple trees which bloom so well producing no fruit, must be attributable to spring frosts destroying the bloom. If you protect them at that season, no doubt you will have fruit.

MANETTI STOCK FOR ROSES (*J. E. Boyd*).—No doubt other stocks may prove as good as the Manetti, but it has proved so free-rooting, hardy, and so easily managed that we do not think it will be easily surpassed. The sorts you mention—*Gloire de Dijon* and *Souvenir de Malmaison*—would neither of them succeed so well, especially the latter, which in the north of England is easily injured by frost; and neither of them would strike in nursery rows in the open ground as the Manetti does. The Rose you sent was most probably *General Jacqueminot*; but it is almost impossible to tell a Rose when sent by letter without water. The colour fades, and the petals fall from the Rose and lose their character.

QUOTATION (*A Subscriber of Some Years*).—The couplet you mention was certainly misquoted, and your own version is also incorrect. In "Hudibras," where it occurs, it reads thus—

"He that complies against his will
Is of his own opinion still."

WEIGHT OF GRAVES, &c. (*J. Lewis*).—The heaviest bunch of Grapes on record is that of the Syrian grown by Speechly at Welbeck, which weighed 20 lbs. We have seen Cucumbers 34 inches long.

NAMES OF FRUITS (*W. G.*).—No. 1 is not Red Astrachan, probably it is Red Wine; 2 is Hawthornden.

NAMES OF PLANTS (*G. W. J.*).—1, *Galium cruciatum*; 2, *Stachys sylvatica*; 3, *Sium officinale*; 4, *Lycopus arvensis*. (*G. M. B.*).—Probably *Malope trifida*, but specimen very imperfect. "The Acaia that the order of Freemasons prize so much," is quite unknown to us. Can any reader supply its name? (*H.*).—*Galaga orientalis*. (*T. L.*).—*Ibus Cotinus*. You can have the "Cottage Gardeners' Dictionary" and Supplement free by post for 7s. 2d. (*Sylpaw*).—*Ibus Cotinus*. The flowers are purple, but these downy threads are the stalks of abortive flowers elongated. (*Birkley*).—An *Asclepiad* with pendulous pedicels, but we cannot say what from the specimen sent. (*T. Pearson*).—1, *Selaginella apus*; 2, *S. Kraussiana*.

advisable in many cases, the argument in other cases does not seem to me so clear.

It is assumed that it is far more easy to breed one first-class pullet or hen than two, and this is true, but not to such a great extent as is assumed. If people will learn to breed, they will have little difficulty in breeding fair matches; and it is quite a mistake to suppose, as I saw stated the other day, that the most successful exhibitors are those who rear their hundreds of chickens. Generally speaking, a man who can breed one really first-class pullet can breed two, and does; still, two birds may undoubtedly be good, and yet not a good match, though here, also, I must remark that our best judges have of late shown a wise discretion in not laying so much stress on mere matching as they used to do, but have given prizes to good birds not an exact match, rather than to birds each of which separately was far worse, but did match. I would only wish to point out that if, by this or any other expedient, winning were ever made really easy, no one would care about winning any longer. All the talk about putting people who do not know how to breed on a practical "equality" with those who do comes to that. It cannot be done, and if it could, the "fancy" and all its charms would be gone.

Still, there are advantages in holding out encouragement to beginners, and even a "Showing-Made-Easy" has its uses like other "Made-Easies." Then, again, early in the year, even a good breeder likes to keep all his hens at home, and is thankful for any rule which only demands one bird away from his yard instead of two. This last is to my mind the strong point of the single-hen system, for the advantage just spoken of will to a great extent disappear as the plan becomes general. As it is, the breeder who has a good pair generally shows at places where pairs are provided, and leaves the single hen for others. But if single hens become general he will be able to make his first-class birds go just twice as far in showing, and will compete at many shows where he now does not. This is a consideration which appears to have been overlooked; but if it be remembered, it will be seen that the very advantages claimed for the single-hen system depend on that system being only partial, not general.

As to show proceeds, my impression is that advantages are pretty equally balanced. Probably entries of single hens are somewhat increased, but I believe, though my belief is contrary to what I have seen advanced, that sales are diminished. I have noticed that the prices of single birds are rarely so low as half that of pairs, and few people care to buy a single hen or pullet. As a matter of fact, I think it will be found that commission on amount of sales on the single-hen plan has nearly always fallen off. On the whole, therefore, I believe that as to show receipts there is little choice either way.

On the other hand, with regard to the effect, as a "show," there can be no doubt that one bird by herself is infinitely inferior. Everyone nearly remarked this at the Crystal Palace—the birds looked dull, tame, and spiritless. As a spectacle merely the plan was an emphatic failure; and I can speak from very careful and special note that four-fifths of the birds could have been matched in pairs of quite satisfactory quality, while the very best ones almost without exception had mates.

My own opinion as to the whole matter will therefore be readily guessed. I think that at shows where the competition is likely to be chiefly local, the single-bird plan is decidedly the best. Especially is this the case during early and spring months when birds are needed for their eggs; and at such seasons even shows of standing might adopt the plan with benefit to the amateur and to their own entries. But at the great shows of the year, when we all want to see the best that can be done, and to compare notes, and to strive in earnest but friendly rivalry, I should much regret to see the system adopted; and I question if it will be, unless it be at shows where mere number of entries is considered as the one great object of contrivance. If it be at these, I feel quite convinced that Birmingham will long be able to laugh at all competitors, for mere number of entries does not necessarily make the best show.—L. WRIGHT.

POULTRY, BEE, AND PIGEON CHRONICLE.

SINGLE BIRDS AT SHOWS.

This subject seems to have "exercised" many good people of late, and it seems to have been assumed that all the arguments have been on the side of showing single hens. I say single hens or pullets, because this is what the question really means; for we are all agreed that as a rule it is best to have the sexes separately. Birmingham—old Birmingham—may her shadow never grow less—taught us this, with many other good things; and her example has been so generally followed, in this one particular at least, that we may almost take separate sexes as admittedly the best arrangement for most shows, at all events of much standing, which can be devised; but, with regard to showing one hen or pullet by herself in a pen, while there is such to be said for it, and I think it may be taken to be really

PUBLISHING THE NAMES OF JUDGES.

We frequently see the names of the committee, treasurer, and secretary of poultry societies attached to the schedule of prizes, but seldom the name of the judge; and if an exhibitor writes to the secretary asking the name of the gentleman selected for that important office, he will mostly receive a very polite reply as follows:—"A gentleman of experience is engaged, but I am not at liberty to give you his name." Now, it is quite possible for him to be a "gentleman of experience" in some matters, yet his knowledge of poultry may be very limited. Some will say if exhibitors know who is to be the judge they may tempt him with a bribe; but I feel convinced the majority of our judges and exhibitors are men of honour, and will not stoop so low. There are, I admit, a few exhibitors who will do anything to win, but those few will always find out who is to judge, whether the name be published or not; therefore, to do

justice to the honest exhibitor, the names of the judges should always be made known, and I am satisfied committees will find it to their interest to give publicity to the matter in the future.

Two of the best breeders and exhibitors in the kingdom informed me recently that they would not send their birds unless they knew who was to be judge, for they had frequently been thrown out, even when showing Birmingham cup-winners, by some of the most miserable specimens. I gave one case in point. At a show not two hundred miles from London one of the gentlemen referred to sent two of his best pens, both of their cup-winners at several of the leading shows. They were placed first and third, and a pair only fit for the spit was second. He asked the judge why the birds were thus placed, pointing out the glaring defects of the second-prize pen. The judge acknowledged he was wrong, but he did not see it thus when he awarded the prize, at the same time saying, "You ought to be a better judge of that variety than myself." A few minutes afterwards the owner of the second-prize pen made his appearance, and, not knowing the owner of the first and third-prize birds, acknowledged to a friend that he was surprised and highly delighted at winning a 30s. prize with his pair of birds, as he only gave 7s. 6d. for them in Leadenhall Market. This is a specimen of the uncertainty of the awards made by one of our present poultry judges. Referring to the same judge, a Hampshire-breeder said, "I know what pleases his fancy; he never gives the prize to the best birds, but if I know any of the north-country judges are to award the prizes I always send my best stuff, or else I stand no chance. Last season I visited a show in the eastern counties, where a Spangled hen, worth about 5s., won the cup, and the best hen in the class, shown by Mr. Deldon, was left out in the cold." In the face of the above facts is it any wonder that many exhibitors owning good birds are determined to keep them at home, unless they know who is to officiate as judge? I hope other exhibitors and secretaries will give their opinion upon the matter. As Secretary of the Lowestoft Poultry Society I may say we always have published, and intend to continue publishing, the names of the judges.—L. WREN.

A DISTINCTIVE FEATURE BETWEEN BRAHMAS AND OTHER FOWLS.

THERE is a feature in the Brahma Pootra fowl which appears to me to distinguish it from all other kinds that I have noticed—viz., that the comb is placed entirely in advance of the eye. A perpendicular drawn through the inner corner of the eye will define the posterior extremity of the comb of the Brahma, whereas a perpendicular between the centre and the posterior corner would define that of the Cochins, Dorking, Game, &c., they having the comb running over the eye. The French breeds of fowl I do not include, as their combs are of quite another distinctive character.

The position of the Brahma's comb to my mind militates strongly against the idea of the Brahma fowl being a cross between any of these breeds, and I am in the habit of judging the degree of purity of a strain of Brahmas in a great measure by this character, other things as per established standard being normal. Further, I believe I may say we do not find this anterior position in any degree in any cross-breeds without there having been an infusion of Brahma blood-royal at some time.

Not having seen this character noticed in print, and it being an observation solely of my own, perhaps you will oblige by publishing it, that I may see what can be said for or against it.—J. R. CROKER, *Mulvern Link*.

[We thank you much for your interesting query. It had never struck us before; but on reading the above, we immediately caught up two good specimens, one Brahma, one Cochins, and submitted them to a close examination. We found, as you observe, a line drawn touching the inner corner of the eye all but cleared the comb and touched only the bare extremity of the point. We may mention the bird was a large and good specimen, with a fully developed comb. On submitting the Cochins-China to the same test, we found a straight line similarly drawn divided the comb as nearly as possible in the centre. We had no others at hand, but we will take an opportunity of trying many other breeds. Being firm believers in the purity of Brahmas, we hail your discovery, not because it makes our opinion stronger—we did not need that, but because such a fact tends to the conversion of those who will not believe because they never have believed. We have had them from the beginning in large numbers. They come always pure, and always true—no sports, no throwing back, no varieties of comb, no uncertainty as to the number of toes, no clean legs. From small beginnings they now form some of the most numerous classes at all shows. Inferior to the Dorking as a table fowl, they are equal to almost any, and they have a great virtue, that they are as hardy as a fowl can well be. They are content in confinement, and we have hatched and reared them in snow.

Cross bred birds are often described as pure ones, and their breeders or owners try to sell them as such. The unfortunate purchasers, breeding all sorts of oddities, condemn the breed as "composite." It is for this reason that discoveries like the above are really valuable.—Eps.]

SEDGEFIELD POULTRY SHOW.

The poultry prizes were not such as to induce any great number of entries, the amounts given being only 10s. and 5s. in each class, with a cup for the best pen in the Show; nevertheless some capital birds were shown. The cup was won by Mr. G. Procter with a grand pen of White Cochins, which were in condition in which Whites are seldom seen at this time of the year. The first-prize *Spanish* were fair in quality, but the rest bad, and in *Brahmas* only the winners were of value. In *Game* the first were Brown Reds in very good feather and good in handling and style; the second, Piles, a little too heavy in feather, but otherwise correct. *Hamburghs* were mixed classes and the entries poor in consequence; the winners were tolerably fair specimens. The only other birds at all noteworthy were the first-prize *Crève-Cœurs* in the Variety class, and the winning *Game Bantams* which were Black Reds; the first-prize chickens, the second-prize adult birds.

The entries of *Pigeons* were numerous, there being three prizes in each class, with four silver cups for the four sections, and the birds were shown singly. The Carrier cocks were a large and good class, but, on the contrary, the hens and both classes of Pouters were only poor; the cup for the section was awarded to a Carrier cock. Almonds were a nice class, the head, beak, and eye properties being striking. The first prize went to a hen, and the second to a cock. Barbs were tolerably good, but some of the best were rather out of bloom. Of Foreign Owls there were but five entries; the first prize went to a good Blue, and the second to a good White. Trumpeters were poor, but the Fantails—an extraordinary class, carried off the cup. Jacobins were good and numerous, and Turbits also a strong class, in which were many capital birds. English Owls were fair in quality, as also were some of the Dragons, while others were inferior. Magpies were exceedingly neat and small. The class for Ice produced some good birds, and the winners were of the Spangled variety. The Variety class contained some good Pigeons, and the cup was carried off by a new variety termed the Whiskered Owl—a rather plain-faced bird, with a half-frill starting from the shoulder points, and turning inwards towards the furl or ruffle.

The *Rabbit* classes were well supported, and more particularly in the Lops, in which class there were twenty-four entries, with not one really bad Rabbit among the lot, and six prizes were allowed to be awarded; the first prize going to a fine Black-and-white doe, extra first to a Black buck. The second prize was taken by a Grey-and-white doe, and extra second by a Fawn-and-white doe. The third prizes were awarded—one to a Fawn, and the other to a Blue doe. The Himalayans were very good in marking, and the Silver-Greys in fur; but the Angoras were not in the best order, though there were some good specimens shown.

It would be impossible to picture a more suitable site for a Show of this description than are the grounds adjoining Hardwicke Hall: the heavy timber serving to protect from the rays of the sun, and forming a welcome shade, while the scenery is sufficient to repay the visitor without other attractions. We published the awards last week.

ORMSKIRK AND SOUTHPORT POULTRY SHOW.

This was held on the 6th inst., when the following awards were made:—

DORKINGS.—*Coloured*.—1, J. Stott, Healdy, Rochdale. 2, J. Robinson, *he*, T. Hornsby, *Chickens*.—1 and 2, T. Statter, Manchester. *he*, T. Hornsby, Latham; Wren & Page, Lowestoft; T. Braiter, Earby, Skipton.
Brahmas.—*Blue*.—1 and 2, J. Robinson, *he*, M. Fairhurst, Ormskirk.
Chickens.—1, B. W. James, Wadley, Berridge. 2, J. Robinson.
Cochins-China.—*Buff*.—1, 2, and Cup, W. A. Taylor, Manchester. *he*, T. Stretch, Ormskirk. *Chickens*.—1 and *he*, C. Sidzwick, Rydleston, Keighley. 2, W. A. Taylor.
COCHINS-CHINA.—*Purplish or Ground*.—1, T. Stretch, 2, W. A. Taylor. *he*, T. Stretch; T. Asplen, Church. *Chickens*.—1, W. A. Taylor, 2 and *he*, C. Sidzwick.
Brahma Pootra.—*Dark*.—1 and 2, F. E. Ansdell, St. Helens. *Chickens*.—1, 2, and *he*, J. H. Fickles, Birkdale.
Brahma Pootra.—*Light*.—1, J. Mitchell, Mossley. 2, C. Lepland, Warrington. *Chickens*.—1, T. A. Dean, Marton. 2, J. Watts.
SPANISH.—1, A. Wickson, Earby. 2, J. Powell, Bradford. *he*, H. Bolton, Bingley; Furness & Sudall, Raatentall. *Chickens*.—1, J. Leeming, Broughton. *he*, H. Bolton.
HAMBURGH.—*Gold-spangled*.—1, G. & J. Beckworth, Chur. h. 2, J. Robinson, *he*, H. Bolton. *Silver-spangled*.—1 and 2, J. Robinson, *he*, H. Bolton.
GAME.—1 and Cup, C. W. Brierley, Millerton. 2, T. P. Lyon, Liverpool. *Chickens*.—1 and 2, G. Peet, Ormskirk. *he*, T. P. Lyon, Liverpool.
BANTAMS.—*Game*.—1 and 2, T. Sharpley, Rawtenstall. *he*, G. Maples, Wavertree. *Any other variety*.—1, H. B. Smith, Preston. 2, E. H. Walton, Rawtenstall. *he*, W. A. Taylor.
ANY OTHER VARIETY.—1 and 2, H. Bolton. *he*, W. A. Taylor.
GESE.—1 and 2, J. Walker, Rochdale. *he*, Capt. G. Anyon, Chorley; T. Harrison, S. H. Stott, Preston. *Brahmas*.—1, W. Penny, Preston. 2, J. Harrison, *he*, R. Barr, Ashton. S. H. Stott.
FONKYS.—1, J. Walker, 2, J. Redwood, Wigan.
DUCKS.—*Lylesbury*.—1 and 2, J. Walker, *he*, J. Robinson, Garstang. *Ruen*,

—I. P. Unsworth, Lawton, Newton-de-Willows, 2, T. Wakefield, Jolborne, *hc*, J. Walker, W. Penny, S. H. Stott; R. Gladstone, jun., Courtney.

PIFFONS.

POUTERS.—*Cock*.—1, T. O. Clinning, Birkdale. 2 and 3, W. Ball, Southport. *Hen*.—1, T. O. Clinning.

CARRIERS.—*Cock*.—1 and Cup, J. Stanley, Blackburn. 2, H. Yardley, Birmingham. 3, T. H. Stretch, Ormskirk. 4, J. Stanley, T. H. Stretch. *Hen*.—1, J. B. Buckley, Aughton. 2, E. C. Stretch, Ormskirk. *Young*.—1, A. Billeveid, Northampton. 2, C. Duckworth, Watlington. 3, E. C. Stretch.

JACOBS.—1 and 2, J. Fielding, jun., Renswaley, 3, F. L. Denny, Southport. *Black*.—1 and 2, J. Fielding, jun., Renswaley, 3, F. L. Denny, Southport. *Blue or silver*.—1, 2, and Cup, F. Graham, Birkensheat. 3, J. B. Buckley, *hc*, F. Graham; E. C. Stretch, Ormskirk; W. G. Union, Chester. *Any other colour*.—1, 2, and 3, F. Graham, *hc*, W. J. Mitchell, Birmingham.

TUMBLERS.—*Short-faced*.—1 and 2, E. C. Stretch, jun., 2, C. Duckworth, *hc*, H. Yardley. *Long-faced*.—1, J. Wats, 2, E. C. Stretch, 3, C. E. Duckworth.

OWLS.—*Foreign*.—1, 2, and 3, J. Fielding, jun. *English*.—1 and 3, J. B. Buckley. 2, P. Unsworth, Lawton. *Jacobins*.—1, H. Yardley. 2, J. Stanley. 3, F. L. Denny, Southport.

TURKEYS.—1 and 2, J. Fielding, jun., 3, J. Wats, Birmingham. *FANTAILS*.—1 and 2, J. F. Lovelock, Newark.

ANTWERPS.—*Short faced*.—1 and Cup, M. Hockford, Croston. 2, J. Stanley. 3, A. Justice, *hc*, W. G. Union, Chester. *Long-faced*.—1, A. Justice, 2, H. White, Manchester. 3 and 4, E. Ashton, Ormskirk.

ANY OTHER VARIETY.—1, H. Yardley. 2, Farness & Sadall, Rawtenstall. 3, R. White.

JUDGES.—*Poultry*: Mr. R. Teebay, Fulwood, Preston; Mr. J. Hindson, Liverpool. *Pigeons*: Mr. R. Teebay, and Mr. J. O. Wakeson.

NEATH POULTRY SHOW.

THE meeting of the Neath Association was held on the 7th and 8th inst., in a large suitable field lent by the Corporation. The pens were Billett's, of Southampton, and were well arranged against the fences, and the only point to which we would take exception was that the bottoms were covered with straw, which answers no good purpose.

The *Dorkings* were a good class for the time of year; the prizes went to Dark Greys. Buff *Cochins* were also good, and the cup was awarded to the first-prize winners, a capital pen; the second-prize pen in the same class contained a good hen but a very small cock, though nice in colour. The Partridge and other Coloured *Cochins* were very poor, and although there were some good and large Dark *Brahmas*, yet they were mostly in bad feather, the Light variety showing little improvement in that respect. Only the first-prize *Spanish* were worthy of notice. Of the Golden *Hamburghs*, Gold-spangled were first and cup for the section, and Golden-pencilled second and third. In the Silvers a pair of good Spangled were first, and Pencilled chickens second. Among *Polands* a neat pair of White-crested Blacks stood first, and Silvers second. Of *Game*, only the first-prize pair were good, but these were awarded the section cup, and were Brown-breasted Reds of rare merit. In *Game Bantams* the first and second-prize birds were Black-breasted Reds; the first adult as good as can be wished for, and the second chickens of this year. In the Variety class, *Creve-Coeurs* were first, and La Flèche second.

There were two classes for chickens, the first for *Cochins*, *Dorkings*, and *Spanish*. The first prize, and the cup for the two classes, were carried off by a grand pen of Partridge *Cochins*; the second prize went to excellent Buff *Cochins*, and the third to Black *Spanish*. In the class for Any other variety of chickens were also some very promising pens, particularly the pair of Light *Brahmas* which won the first prize, and the pen of Dark birds of that variety which won the second prize. The third-prize Duckwing *Game* were capital in colour and style, but slightly duck-heeled. An extra third prize was awarded to *Creve-Coeurs*.

Rouen *Ducks* were very good, but the Aylesburys were something wonderful in size, condition, and colour of beak; and the cup for the aquatic birds and Turkeys was awarded in this class. In the Variety class of Ducks was a neat pen of Black East Indian. Only one pen of *Geese* was shown, and these were Toulouse, but there were three pens of *Turkeys* of great size and in good order.

Of *Pigeons* the Carriers were very poor, in fact little more than Dragons, but all the Pouters were mentioned, the first and second prize-winners being White, in grand show, and long in limb and feather. Only one pair of Tumblers was exhibited, and the Jacobins were very poor. The winning Fantails were birds of this year, good in carriage and style of tail, and the cup for the best pen in the Show was awarded to the first-prize pen. Nuns were good; the first prize was taken by nestlings, and the second by old birds. Barbs were of ordinary merit, the first were Yellows and the second Reds, no others being worthy of notice with the exception of the winners of the first prize in the Variety class, which were Silver Runts of great size.

Among the *Carnaries* were some neat birds; the first prize went to a Crested Jonque Norwich, the second to a first-feather Dutch, and the third to a common Yellow. An aviary of wild birds was awarded an extra prize.

DUCKS.—1, E. Tr. Alwood, Tring. 2, W. Boyan, Swansea. 3, H. Tush, Swansea. 4, W. Boyan; C. Harris, Neath; K. Davidson, Bridgeton.

CARRIERS.—1 and Cup, T. A. Dean, Marsden. 2, C. Bloodworth, Beltham (Buff). 3, S. R. Evans, St. Day (Buff). 4, H. Peas, Buff. 5, C. E. Bloodworth, Swansea. *Any other variety*.—1, B. P. Bidder, Warrington. 2, J. H. Wats, *hc*, Renswaley. 3, D. Hart, *hc*, Penryn. 4, J. B. Buckley, *hc*, Aughton.

TUMBLERS.—*Short-faced*.—1, H. B. Morrill, Colmar, Cliffe, Dalton. 2, P. B.

Williams, Brecon. 3, E. P. Bidder. *hc*, W. Boyan. *Light*.—1, T. A. Dean. 2, Rev. N. J. Ridley, Newbury. 3, H. Feast. *c*, H. Studdy, Ashdale.

SPANISH.—1, H. Feast. 2, T. Ace, Ystalyfera.

HAMBURGHS.—*Golden pencilled and Spangled*.—1, Cup, and 3, Mrs. Rolfs, Monmouth. 3, C. Bloodworth, *hc*, H. Moore, Weston-upon-Mare; Mrs. H. Feast; Mrs. E. Feast; J. F. Davies, Neath. *c*, C. Buckland, Swansea. *Silver-pencilled and spangled*.—1, Mrs. Rolfs. 2, J. McCannell, Hereford. 3, Mrs. E. Feast. *hc*, Mrs. H. Feast. *c*.—Farrah, Neath.

POLANDS.—1, S. Jones, Neath. 2, C. Bloodworth. 3, Mrs. H. Feast. *GAME*.—1 and Cup, H. E. Martin, Fakenham. 3, A. Feast. *c*, T. Reece, Llandoff; J. Lewis, Neath.

ANY OTHER VARIETY.—1 and 3, A. Ashley, Worcester. 2, R. Wingfield, Worcester. *hc*, H. B. Pease, Brecon.

BANTAMS.—*Any other variety*.—1, A. Feast. *ANY OTHER DISTINCT VARIETY*.—1, J. Robinson, Garstang (Creve-Coeur). 2, Rev. N. J. Ridley, Newbury. 3, A. Feast. *hc*, Mrs. E. Feast. *c*, F. J. Gibbins, Neath (Chinese).

COCHINS, DORKINGS, AND SPANISH.—*Chickens*.—1, Cup, and *c*, P. Charles, Neath (Partridge Cochins). 2, C. Bloodworth (Buff). 3, A. T. Walters, Kidwells (Buff Spanish). *hc*, W. Boyan (Dorkings); D. Laine, Hardwick (Buff Cochins); D. F. Crosswell, Bagshot (Silver-Grey Dorkings).

ANY OTHER VARIETY.—*Chickens*.—1, T. A. Dean. 2, O. E. Crosswell, Early Wood, Bagshot. Extra 2, J. Cker, Hafod, Swansea. 3, D. W. J. Thomas, Brecon. Extra 3, A. Feast, Swansea. *hc*, Mrs. H. Studdy, Ashdale, Haverfordwest; W. Morris, Hereford; J. F. Davies, Neath. *hc*, Mrs. H. Studdy; W. Harris (2); J. Carr. *c*, J. F. Davies.

DORKS.—*Long*.—1, J. A. Lewis, Brecon. 2, S. H. Stott, Preston. 3, J. R. Paramore, Neath. *hc*, Mrs. Richard, Brecon; W. W. Cunnick, Brecon. *Any other variety*.—1 and Cup, T. Tomlinson, Lancashire. 2, S. R. Evans, St. Day. Cornwall. 3, Mrs. E. Feast, Swansea. *hc*, Mrs. H. Studdy; Mrs. H. Feast. *Any other variety*.—1, Mrs. Lewis, Neath. 2, Mrs. E. Feast. 3, H. Cuthbertson, Porthewlyn.

GESE.—1, Mrs. H. Studdy. 2, Rev. N. J. Ridley. 3, Mrs. Lewis. *TURKEYS*.—1, Mrs. H. Studdy. 2, Rev. N. J. Ridley. 3, Mrs. Lewis. *SELLING CLASS*.—1, D. J. Rhys, Neath. 2, W. Harris. 3, Mrs. R. Morgan. *hc*, A. E. Thomas.

DUCKS.—1, J. R. Paramore. 2, W. W. Cunnick (Rouen). 3, J. F. Davies (Aylesbury).

PIGEONS.

CARRIERS.—1, P. R. Spencer, Hereford. 2, W. Merriman, Swansea. *POUTERS*.—1, W. H. Tomlinson, Newark-on-Trent. 2, H. Yardley, Birmingham. *hc*, P. R. Spencer; T. A. Dean, Marsden. *c*, P. R. Spencer.

TUMBLERS (Short-faced).—1, H. Yardley. *JACOBS*.—1, H. B. Price, Brecon. 2, W. G. Davies, Swansea. *FANTAILS*.—1, Cup, and 2, W. H. Tomlinson. *hc*, W. Merriman.

NUNS.—1 and 2, T. A. Dean, Hereford. *BIRDS*.—1, H. Yardley. 2, W. H. Tomlinson. *ANTWERPS*.—1, H. Yardley. *TERMS ON OWLS*.—1, H. Yardley (Owls). 2, J. Croote, Heavitree, Exeter (Turbit).

EXHIBITING TUMBLERS (pen of not less than six).—1, P. Charles, Neath. 2, J. Weston, Neath. *c*, W. M. Davies, Neath.

ANY OTHER VARIETY.—1, Mrs. H. Studdy, Ashdale, Haverfordwest (Runts). 2, P. R. Spencer (Trumpeters). *hc*, W. G. Davies.

CANARY.—1, B. P. Bidder, Wannechurch. 2, E. Spooner, Baglan Hall. 3, J. Baylis, Neath. *hc*, A. Shepherston, Neath; R. Roe, Swansea; S. Daniel, Neath (4); B. P. Bidder. *c*, S. Daniel.

HORNINGLOW POULTRY SHOW.

THIS Show was held on the 8th and 9th inst., at Burton-on-Trent, and proved unexceptionally good. The arrangements were of a very superior character, the method adopted for the staging of the poultry being alike unique and satisfactory. As rapidly as possible the staging was completed by the simple plan of turning on end a number of empty ale casks, and then placing planking on them to receive the pens, supplied by Turner, of Sheffield. The casks proved to be a foundation incomparably secure, and the erection was completed with almost inconceivable rapidity. Such a hint to committees, if pressed for time, may be useful. Another point in the management is quite worthy of note—viz., that in every instance in which there appeared to be the slightest question as to the birds reaching their owners on the Saturday evening, they were carefully retained and attended to during the Sunday, and sent away by the earliest trains on the Monday morning. Excursion trains from distant localities brought together an immense number of visitors, and this, with the fact that a popular candidate for the district was simultaneously returned to Parliament, lent much excitement to the doings of the day, and made the Show an extraordinarily paying one. It would be well, perhaps, to revise the prize schedule for future shows, as neither Ducks, Geese, nor Turkeys had any place on the prize list, proving the only drawback to an otherwise excellent Exhibition.

The greatest feature of the Show was the *Hamburgh* classes, the Duke of Sutherland, Mr. John Rollinson, Mr. Henry Beldon, and a few others of high repute for these breeds, making prize-winning "a far harder job than anticipated." Such a collection of the grandest pens in the kingdom formed a *Hamburgh* show that once seen could never be forgotten. Among other objects of especial interest were the well-grown chickens of most of the larger breeds of poultry, that were brought to the show-pen in most creditable condition. *Cochins* and *Dorkings* were very fine, though, as most persons would anticipate, many of the adults were much out of plumage. The Golden and Silver-spangled *Polands* proved irresistibly attractive to the visitors, being represented by some of Mr. Beldon's best specimens; there were also some very fine *Mallards*, *Silky fowls*, and *Lep-lorns*. Some very good *Game Bantam* chickens were shown, but as yet too young for exhibition.

The most perfect order and good humour prevailed among the crowds of visitors who attended, and the weather was as

propitious as even the most anxious committeeman could have desired.

DORKINGS.—I, J. White, Warley, Northallerton. 2, Rev. E. Bartrum, Berk hamstead. 3, H. Yardley, Birmingham. *hc*, J. Watts, Birmingham. *c*, E. J. Draper, Burton-on-Trent; J. Tyler, Loughborough.

COCHIN-CHINA.—Buff—1 and *hc*, Mrs. Allison, Worcester. 2, H. Yardley. 3, H. Tomlinson, Birmingham. *c*, J. Ward, Ashby-de-la-Zouch. *Any other variety*.—1, H. Beldon, Gortstock. 2, S. H. Turner, St. field. 3, R. S. S. Woodgate, Fernbury. *hc*, M. M. Cashmore, Sheepshed.

BRAHMS.—Dark.—1, J. F. Smith, Sheffield. 2, E. Kendrick, jun., Lichfield. 3, H. Beldon. *hc*, J. Watts; Dr. Holmes, Chesterfield. Light.—1, H. Beldon. 2, J. Mitchell, Moseley, Birmingham. 3, A. O. Worthington, Burton-on-Trent. *hc*, E. Kendrick, jun.

SPANISH.—Black.—1, H. Beldon. 2, Pickering & Duggleby, Driffield. 3, Mrs. Allison. *hc*, H. F. Cropper, Walsall.

GAME.—Black Red.—1, R. Ashby, Nantwich. 2, Duke of Sutherland, Trentham Hall. 3, E. Wright, Horninglow. *hc*, J. Mason, Worcester; E. Wright, Brown Red.—1, J. Glassbrook, Burton-on-Trent. 2 and 3, E. Bell, Burton-on-Trent. *hc*, R. Ashley. *Any other variety*.—1, E. Bell. 2, R. Ashley. 3, E. Windwood, Worcester.

HAMBURGS.—Golden-spangled.—1, J. Rollinson, Lindley, Otley. 2, H. Beldon. 3, C. Dawes, Burton-on-Trent. *hc*, J. Rollinson (2); Duke of Sutherland; H. Feast, Swansea; T. Walker, Donon. *c*, J. Ward; S. W. Halkam, Whitwick. Leicester. *silver-spangled*.—1 and 3, J. Rollinson. 2, H. Beldon. *hc*, Duke of Sutherland; A. Sinclair, Burton-on-Trent; G. Hanson, Burton-on-Trent. *c*, G. Boote, Burton-on-Trent; H. Feast.

HAMBURGS.—Golden-pencilled.—1 and 2, H. Beldon. 3 and *c*, J. Rollinson. *hc*, Duke of Sutherland; H. Feast. *silver-pencilled*.—1 and 3, H. Beldon. 2, Duke of Sutherland.

BANTAMS.—Black or Brown Red Game.—1, C. Scammells, Trowbridge. 2, J. Richardson, Loughborough. 3, Duke of Sutherland. *hc*, E. Bell; C. Pratt, Burton-on-Trent. *c*, R. Ashley. *Any other variety of Game*.—1, R. Ashley. 2, J. Watts. 3, W. L. Mason, Chesterfield.

BANTAMS.—*Any variety except Game*.—1, H. Beldon. 2, T. Cropper, Bacup. 3, H. Feast. *hc*, Duke of Sutherland.

FRENCH.—1 and 2, R. B. Wood, Uttoxeter. 3, W. Dring, Faversham. *hc*, H. Feast; Rev. N. J. Bidley, Newbury.

ANY OTHER VARIETY.—1 and 2, H. Beldon. 3, E. J. Draper. *hc*, E. Kendrick; W. Jones, Walsall. *c*, Rev. N. J. Bidley.

WAZZ.—Cuck.—1, J. Richardson. 2, Duke of Sutherland. 3, R. Ashley. BRAHMA.—Cock.—1, Rev. N. J. Bidley. 2, H. Beldon. 3, Dr. Holmes.

The prizes were awarded by Mr. Edward Hewitt, of Sparkbrook, near Birmingham.

BISHOP AUCKLAND POULTRY SHOW.

THERE were something like three hundred pens shown here, although the prizes were small; in some of the classes, however, the birds were of great merit. Dorkings were a good class, and the first and second-prize Cochins, which were respectively White and Buff, proved extremely fine; but the Hamburgs were of an ordinary character. The Game class contained some very good birds, the winners being Brown Reds. Of Polands, the Golden were in good order, and the winners very good in crest and colour; as also the first-prize White-crested Blacks in the next class. Game Bantams were poor as a whole. The medal for that variety was won by the Black Reds. The Rouen Ducks were very large, and good in all particulars, and the Widgeons, to which the first prize was awarded in the Variety class, a neat good pair. Turkeys and Geese were large and in fair feather.

The above remarks apply to the adult poultry, but it was in the chickens that we found the most noteworthy collection. Dorkings were good and forward. The first-prize Buff Cocker cockerel in our opinion gave promise of great size, the pullet being well made-up; the second-prize pullet was also a sound-coloured bird. Whites were good but small, the Brahmas poor, and the Hamburgs only moderate in all classes. The Game chickens were a grand collection, the winners being Brown Reds in the first class, and Duckwings in the second. The Polands were Golden, and very forward and good, but in Red Game Bantams, only the first-prize winners were noticeable. In the next class Piles won both prizes, and the run was very close between the two pens.

In Pigeons, the first in Carriers was a Black, and the second a Dun cock, both moderate birds. The Pouters were all Blue-pied, and the winners in good order, large, and well marked. Both the winners in Tumblers were Almonds of good quality. Fantails were a fair lot, the first-prize birds being very good. In Trumpeters, only the two winners, which were Black, were of any merit. Jacobins were a capital lot, the winners being both Red hens; the first very small and neat in all points, the second only losing in size. Turbits were also good, the first a Blue of great character, and the second a very good Red, but rather large. English Owls were a moderately good class, and the variety good; a well-developed Yellow Barb was first, and a very handsome-faced Pigeon second.

The medal for points in poultry was won by Mr. Thomas Robson.

DORKINGS.—1 and 2, C. & A. Widdas, Beechburn Grange. *hc*, C. & A. Widdas; J. T. Proud.

COCHIN-CHINA.—1 and 2, G. H. Proctor, Durham. *hc*, J. Russell, Whitby; A. Bahar, Bishop Auckland; C. & A. Widdas.

BRAHMA POOTRA.—1, R. Moore, Durham. 2, R. Shields, Swatwell. SPANISH.—1, R. Moore. 2, H. Dale, Northallerton. *hc*, A. M. Bahar; R. Moore.

HAMBURGS.—Silver-spangled.—1 and 2, R. Moore. *hc*, W. Hodson, Evenwood. Golden-spangled.—1, R. Beeveside, Bishop Auckland. 2, T. Liddle, Bishop Auckland.

HAMBURGS.—Silver-pencilled.—1, R. Moore. 2, J. Russell, Whitby. *hc*, W. Jopping, Frosterley; W. Simpson, Frosterley. Golden-pencilled.—1, W. Atkinson, Bishop Auckland. 2, R. Moore. *hc*, V. Johnson, Frosterley.

GAME.—Black-breasted and other Reds.—1, C. E. Morgan, Bishop Auckland. 2 and *hc*, T. & J. Robson, Bishop Auckland. *Any other variety*.—1, T. & J. Robson. 2, T. McKenzie, Stanhope (Duckwing). *hc*, C. & A. Widdas.

POLANDS.—Golden.—1, C. E. Morgan. 2, J. T. Proud. *hc*, C. Walker; J. T. Proud. *silver-spangled and white-crested Black*.—1, J. T. Proud. 2, C. E. Moore.

GAME BANTAMS.—Black-breasted and other Reds.—1 and Medal, J. Ferry. 2, J. & W. Gill, Bishop Auckland. *hc*, J. Ford, Bishop Auckland; T. Ayre, West Auckland. *Any other variety*.—1, J. & W. Gill (Duckwing). 2, T. & J. Robson. *hc*, W. Atkinson.

BANTAMS.—1, A. M. Balmer. 2, A. Mitchell, Bishop Auckland. *hc*, R. Moore. Ducks.—Aylesbury.—1, O. A. Young, Driffield. 2, J. G. Milner, h's, T. Gibson; C. E. Morgan. Rouen.—1, W. Simpson. 2, J. T. Proud. *hc*, J. G. Milner; A. M. Balmer. *Any other variety*.—1, J. G. Milner (Widgeons). 2, O. A. Young. *hc*, J. G. Milner; Mrs. Quoch, Ferryhill (Widgeons); O. A. Young.

TURKEYS.—1, Mrs. Sanderson, Wolsingham. GESE.—1, O. A. Young. GUINEA FOWLS.—1, O. A. Young. 2, J. Robson.

ANY OTHER VARIETY.—1, T. & J. Robson. 2, R. Moore. *hc*, J. Russell, Whitby (Black Hamburgs); J. T. Proud.

CHICKENS.

DORKINGS.—1 and 2, C. & A. Widdas. *hc*, C. & A. Widdas; T. Stanfield, Sunderland. COCHIN-CHINA.—Buff.—1, 2, and *hc*, G. H. Proctor. *White*.—1, G. H. Proctor. 2 and *hc*, G. Bell, Beechburn.

BRAHMA POOTRAS.—1, J. Russell. 2, J. H. Blackwell. SPANISH.—1, O. A. Young.

HAMBURGS.—Silver-spangled.—1 and 2, T. Ayre. Golden-spangled.—1, R. Keeleyside, Bishop Auckland. 2, W. Tinkler, St. Helen's, Auckland. HAMBURGS.—Silver-pencilled.—1, W. Jopping. 2, J. Russell. *hc*, W. Simpson; T. Stanfield. Golden-pencilled.—1, R. Keeleyside. 2, J. Ferry. *hc*, J. Russell.

GAME.—Black-breasted and other Reds.—1, T. & J. Robson. 2, C. & A. Widdas. *hc*.—Elms: T. & J. Robson. Duckwings and other Greys.—1, T. & J. Robson. 2, T. McKenzie. *hc*, Mrs. Ellis.

POLANDS.—1 and 2, J. T. Proud. GAME BANTAMS.—Black-breasted and other Reds.—1, T. & J. Robson. 2, W. Grey, Tow Law. *hc*, J. Ford. *Any other variety*.—1, T. & J. Robson. 2 and *hc*, W. Gray.

BANTAMS.—1, T. & J. Robson. 2, T. Alderson. POULTS.—1, J. T. Proud. 2, J. Robson.

GOSLINGS.—1, J. T. Proud. 2.—Harrison, Bolam. *hc*, J. Robson. ANY OTHER VARIETY.—1, R. Moore. Extra 1, J. G. Millner (Hoodans). 2, J. Russell, Whitby (Black Hamburgs).

SPECIAL CLASS.—Cock, Cockerel, or Drake.—1, C. & A. Widdas. 2, J. T. Proud. *hc*, J. Russell; A. M. Balmer; C. E. Morgan; W. Atkinson; C. & A. Widdas; R. Curry (Black Hamburg). *c*, J. Sherwin, Ripon; J. Robson; C. E. Morgan; C. & A. Widdas (3). Hen, Pullet, or Duck.—1, J. Sherwin. 2, J. T. Proud. *hc*, A. Harburn, Bondgate; T. & J. Robson; C. & A. Widdas (2); F. Horseman (2). *c*, J. Russell.

PIGEONS.

CARRIERS.—1, R. Blacklock, Sunderland. 2, S. D. Eadley, Hereford. *hc*.—YOUNG.

POUTERS.—1 and *hc*, T. Rule, Gilesgate. 2, J. Kilpatrick, Whitby. TUMBLERS.—1 and 2, E. Dodds, Durham. *hc*, C. E. Morgan.

FANTAILS.—1 and *c*, T. Rule. 2 and *hc*, J. F. Lovelidge, Newark. TRUMPETERS.—1 and 2, T. Rule. *hc*, S. D. Eadley.

JACOBS.—1, T. Rule. 2 and *c*, J. Young. *hc*, R. Balmer (2); T. Rule. TUMBLES.—1 and 2, J. Young, Bishop Auckland. *hc*, J. F. Milner; J. Young (2).

OWLS.—English or Foreign.—1, J. Young. 2, T. W. Kilburn, Bishop Auckland. *hc*, T. W. Kilburn; R. Blacklock; J. Young.

ANY OTHER VARIETY.—1, J. F. Fawcett, Whitby. 2 and *hc*, M. Ord, Sedgefield. *hc*, J. S. Baddeley (Barb); J. Young (Barb); T. W. Kilburn.

RABBITS.—1, C. E. Morgan. 2, W. A. Robinson, Winstone (Lop eared). *hc*, G. Kington, Bishop Auckland; M. M. Mearns, Bishop Auckland (3); J. T. Robinson, Darlington. *c*, A. Gardner, Bishop Auckland; G. Oswald, Durham.

SOUTH LONDON FANCY RABBIT SHOW.

This was held at the Goat's Head, Cleaver Street, Kennington Cross, on the 11th inst. The following are the awards:—

Table with columns: Prize, Name, Breed, Length, Breadth, Weight, Age. Lists awards for various rabbit breeds like Fawn Doe, Sooty Buck, Black-and-white Buck, etc.

BROWN LEGHORNS.

A VARIETY still more esteemed is the Brown Leghorn, which has come into considerable notoriety of late in the United States. It appears to have been bred for some time, but little known; and the description in the published editions of the "American Standard of Excellence" is grossly inaccurate and incomplete, evidently owing to ignorance of the fowl. During the last two seasons, however, the breed has become more and more popular, and in 1872 eggs of it were advertised at the high price of \$10 per dozen. From an article by Mr. A. M. Halsted on Brown Leghorns, in the New York Poultry Bulletin of May, 1873, we make the following extracts:—

"This beautiful variety is daily growing in favour and popularity, and bids fair, at no distant day, to excel the White variety in the estimation of amateurs and breeders.

"Rather larger than the Whites, they are also more hardy, and being a yellow-skinned fowl, are more pleasing in appearance to the epicurean tastes of our fanciers. As egg-producers they are unrivalled; pullets frequently commencing to lay at four and a half months old, and continuing without cessation until well into the winter. Among New Hampshire farmers they are quite popular, owing to their strong constitution and

their excellent health during the long tedious winters. It is only quite lately that they have created any sensation at our poultry shows, and only the past year that the numbers shown have made the work of the judges anything more than a short inspection.

"The earliest knowledge we have of them is from Mr. F. J. Kinney, of Worcester, Mass., who writes:—"The first I ever owned I bought on board a ship in Boston Harbour, in the spring of 1833. This was the first trio I ever saw, and I believe them to have been the first ever brought to America. I have since had two other small lots direct from the city of Leghorn, in Italy, and expect more soon from the same place. The first trio weighed 9 lbs. 3 qrs., and were yearlings. Their combs and wattles were very large and coarse; ear-lobes entirely red, same as face, comb, and wattles. They were not Black-Red Games, nor Black-Red Leghorns, but Brown-Red—*i.e.*, the cock's breast was dark brown, spotted with lighter brown, the dark brown running-up the under side of the neck; his hackle was light brown, striped with black; the hens were feathered and coloured the same as the good ones are now, the colours being very distinct, and the pencilling the most beautiful of any fowl I ever saw, and the most distinct."

We have seen that there is some doubt as to the origin of the White breed; but besides the above importation, many others from Leghorn have been made since of the Browns, so that in their case at least the name is appropriate enough. Of this fact we have not the slightest question, having had it confirmed from numerous American correspondents, who testify to having seen birds recently imported either from Leghorn or other parts in Italy; but as to another point named by Mr. Kinney, the colour of the ear-lobe, there seems to be a great difference of opinion among American fanciers—Mr. Halsted and some others believing that the deaf ears on the earlier importations were red, while Mr. A. Beard, Mr. W. E. Bonney, and other breeders, say the early birds had white ears. The natural supposition would be that both were imported; and the difference is of little consequence, since all agree that the deaf-ears ought to be white. Of this there can be no question, as it not only agrees with the whole Leghorn or Spanish type, but is incomparably superior in appearance. There is, however, yet much difficulty in breeding all the chickens with white ears, but this, no doubt, will be accomplished before long.

American breeders have unquestionably much improved the Brown Leghorn since its first importation, which would account for the breed only lately coming into notice. Mr. W. E. Bonney writes of them:—

"In Brown Leghorn fowls, their gay plumage, lively appearance, and, in fact, every feature connected with them, is attractive and pleasing; and in this class we must soon recognise the leading variety, whether for fancy or profit. They mature early; I have known pullets to commence laying at three months of age, and continue laying during the entire season. They are non-sitters; and I never saw a case of roup or any hereditary disease among my fowls during the whole period of my successful breeding. I have bred all classes of fowls, and by far give the Brown Leghorn the preference; I shall continue making a speciality of them, adding fresh-imported blood when needed. I have bred them since 1869 (the first importation ever made into this country being in 1855), and when I commenced to breed they would hatch all colours—brown, black, Dominique, and in 1862 I had one white chicken in a pullet. Since then I have added fresh blood, sparing no pains to get select stock, and by careful breeding have accomplished their hatching true to colour."

The first Brown Leghorns ever received in England were sent to ourselves, by the kindness of Mr. A. M. Halsted, specially for portraiture in this work. They arrived on June 17th, 1872, one hen again being unfortunately injured in some way, bleeding profusely from the beak, and dying a few hours after receipt. The other hen laid next morning, and continued for a few days, when she stopped; this fact, as in the White birds sent us, showing well the laying qualities of the breed. We might describe the birds very briefly as combining the Spanish comb and type of head and body, with the colour or plumage of Black Red Game of a rather darkish tinge; the cock being a black-breasted bird, with hackles orange-red striped with black, and the hen salmon-breasted, with rest of the plumage partridge-marked, or brown finely pencilled over with dark markings. They are somewhat larger than White Leghorns, and rather shorter on the leg, averaging about half a pound heavier in the opinion of American breeders.

Being anxious to test the stock, and having some suspicion the birds might have been created by crossing White Leghorns with Game, we hatched a brood of chicks on the 1st of August; except one or two broken, every egg hatched, and not a chick died. We know no fowls which feather so quickly, except Houdans and Andalusians. Being very short of room and accommodation, owing to a recent removal, the chicks had an open shed to roost in, but grew up perfectly hardy, and with no care whatever, in spite of the very late date of hatching. They were

very uniform in colour in their first feathers, but in their second or adult plumage two of the cockerels moulted black, all but some reddish feathers on the hackle and wings. The pullets varied little, two being just like the mother, and the rest of the same type, but darker, somewhat like darkish grey Dorkings. One cockerel was just like the father, and a fourth brown-breasted. On the whole, and considering the want of what English fanciers consider careful breeding in nearly all American stock, we were surprised and gratified by the degree of uniformity thus apparent, and fully convinced that the breed was genuine, or a really distinct race.

Tastes differ, but we were much pleased with these fowls, and much regretted that utter want of accommodation at that time prevented our keeping more than our old favourites, the Brahmas. A neater and more pleasing style of bird could not possibly be; and as layers we consider this breed the best we have ever met with for moderate confinement. The Silver-spangled Hamburg may even surpass it on a wide range, as regards the number of eggs, but these are inferior in size; and the Brown Leghorn will thrive in a moderate-sized yard. The hen laid an egg nearly as large as that of a Spanish fowl, and after moult recommenced early, before any of our Brahmas had "begun to think about it."—(*Wright's "Illustrated Book of Poultry."*)

SWARMS AND HONEY HARVEST, 1873.

I COMMENCED this season with four boxes and four skeps, mostly fed liberally till May. The apple blossom was hardly used, the weather being bad and chilly; however, towards the middle of May I made two artificial swarms, which are doing fairly well. On June 19th I had a weak swarm, which died out or disappeared during my absence, having built some small pieces of comb; on June 22nd a very strong swarm, the largest I have ever seen, from one of the artificial swarms made in May, and transposed at once with the original stock. The various hives have built plenty of comb, but have no great stores of honey. Last year the lime blossom did wonders, this year it showed very little results.

I may perhaps just have honey enough for the winter, though I doubt this, and shall have, as compared with last year, six boxes and five skeps. My boxes are of the German type, of which I imported a pattern years ago.—*Buz, Gloucestershire.*

BEE-GOSSIP.—No. 1.

THE honey season in Devonshire, so far as I have been able to gather from my own experience and the reports of other bee-keepers, has been a very unfavourable one, more particularly for those who endeavour to obtain their share of their favourites' labours by the use of extra boxes or hives as supers, nadders, or otherwise. Very few of these have been completed, and fewer still have been filled, without several of the combs having been largely occupied by brood. We have had short spells of pretty good honey-gathering, but these have been generally succeeded by much longer intervals of unfavourable weather, in which the bees have been able to collect but little, added to cool nights, which drive the bees down from the supers—conditions altogether antagonistic to super-filling. The queens, under such circumstances, are much more likely to ascend for the purpose of laying eggs in the sparsely-occupied combs than when these last are being rapidly stored with honey. I think that cottagers' hives will generally be found tolerably well supplied with honey, with the exception of very late swarms. Swarms from cottage hives, so far as I have been able to learn, have been most uncertain. Some made their appearance in May, many did not swarm till July, and others hung out in large clusters under the floor-boards and round the hives for several weeks without swarming at all, thereby wasting the best part of the summer.

In my own experience this season with artificial swarms, and also of raising queens in nucleus boxes for this purpose, I have had more than usual disappointment. From the brood combs of my best Ligurian colony, from which I drove the bees to make a large artificial swarm, I succeeded in obtaining more than twenty sealed royal cells, which were distributed among various small and large families of queenless bees. The majority of the queens hatched out satisfactorily, giving promise of success, but, on subsequent inspection, several were missing, having probably been lost on their wedding trips, thus necessitating the entire process of queen-raising to be gone through over again. Also others of these young queens were a very long time before they commenced laying, so long in some cases that, not being able to find the queens or any signs of egg-laying, I concluded them also to be among the missing, and supplied the supposed disconsolate bees with royal cells or suitable brood-combs for raising fresh queens. A few days after, finding the royal cells given had been torn to pieces, and no royal cells commenced in the brood-combs supplied to the others, a search revealed the fact that queens had been present all the time, though their breeding had been unusually delayed. Not having been sufficiently particular in observing the dates of the

various manipulations, I am unable positively to state how long a time elapsed between the birth of the young queens and their first laying of eggs. I must, however, do justice to some of them in saying that subsequently they have proved themselves to be very prolific. I must now conclude this chapter of bee-gossip, but hope to write a second very shortly, giving a few more details of what has occurred in my apian practice this season.—S. BEVAN FOX, Exeter.

A BEVERAGE FROM ROASTED GRAPE SEEDS.—MONS. T. Schmidt calculates that 30 to 40 lbs. of seeds per acre of vineyard are ordinarily produced, and, with the exception of the tannin which they contain, and which is used in the clearing and manufacturing of wine, the whole is looked upon as a waste product. When, however, these seeds are properly roasted and ground, they possess an aroma very much like that of East India coffee, and the beverage obtained therefrom is about the same in taste, although not in strength, as coffee. The author recommends the following mode of procedure:—Take 1½ ounce of the ground preparation, and boil it for five minutes in a quart of milk, adding a little cinnamon and cloves. When filtered and sweetened to taste, a beverage is obtained resembling chocolate, with the same reddish tint. It also becomes thick like cocoa on being allowed to stand for a while.—(English Mechanic.)

OUR LETTER BOX.

Books (J. P. G.).—Morris' "Birds and Nests," published by Messrs Groombridge, Paternoster Row, in half-crown parts.

EDGEFIELD POULTRY SHOW.—The Secretary requests us to state that the first and second prizes for Cochins, also the cup, were awarded to Mr. G. H. Procter, Market Place, Durham, and not to Mr. P. A. Denham, as erroneously published last week. In Pigeons the following corrections are also made:—viz.:—Barbs, —1 and Cup, J. P. Fawcett. English Doves,—1, J. Dye. Any other variety,—1, Cup, and Extra 3, J. & W. Towerson. No Extra 2 was given.

BLACKBURN POULTRY SHOW (Correspondent).—Thanks, but the time which has elapsed is too great.

HASLINGDEN POULTRY SHOW.—In the Antwerp class second prizes were awarded to Mr. A. Justice, Mr. J. Stanley, and Mr. F. Woodhouse, there being three second prizes, and not two only, as the class was so good.

BRAHMAS NOT FEEDING FREELY (Colon).—You need not be uneasy that the appetite of your Brahmas falls off. Your feeding is good enough for any fowls. At this time of year they pick up much food over three acres. They have always been well fed, and consequently, having no lost ground to make up; they do not want as much food as fowls that are fed irregularly, or that have been underfed for some time. Continue to feed in the morning on slaked barley meal, mid-day give some Indian corn, and at evening repeat the slaked barley meal. With the range they have they require no more than this, and if they eat but little, so much the better for you. Backwater is not good for fowls, and it is more than likely if you gave it to them they would not touch it. Fowls only that are reared on it, as they are in France, are fount of it.

BREEDING BRAHMAS AND COCHIN BANTAMS (Cockerel).—In all breeding the first and essential point is to have stock you can depend upon, and having that, to choose your breeding birds from those that possess the qualities you wish to perpetuate. All the early-imported Brahma cocks (Dark) were speckled-breasted. A light-breasted Dark Brahma cock is an impostor; but the condemnation of a bird with a rich black breast regularly spotted with white, is not warranted by the history of the breed. It has long been known that it is very difficult to breed winning cocks and hens from the same birds, but it is not impossible. We differ from those who deery fresh blood. If we want to get any feather or property, we choose parents that possess them. The point we avoid in all Dark Brahma breeding is a buff tinge on the breasts and wings of the hens, or on the wings of the cocks. Light breasts in the hens are very common—almost the rule, but it is more desirable to choose breeding stock in which (as you want black-breasted cocks) the cocks have black breasts, and the hens are pencilled to the throat. We do not believe Cochin Bantams can be made; at any rate we cannot make them. We have tried, and bred enthusiasts. We have had imported birds that were perfect. Mark your fowls with different coloured leather or cloth round the legs.

POINTS IN SHOW CANARIES (William Savage).—Your being an invalid and unable to attend shows is to be regretted, for it is with birds as with other things, one practical lesson is worth pages of descriptive matter, and one visit to a show of high-class birds would teach you more than any pamphlet on the points of show birds with which I am acquainted. Several such have come under my notice from time to time, but it would not be difficult to drive the traditional coach-and-six through the best of them, which, apart from being very dogmatical, are for the most part effusions lacking any element of refinement, and are withal redolent of that peculiar atmosphere which permeates the back parlour of a beer shop. The Canary has for a lengthened period been in the hands of, possibly, not the best educated part of the community, though he is none the less to be admired on that account, nor are his friends the less to be commended for their discrimination in selecting such an interesting object for their attention. His literature, therefore, or that part of it more particularly relating to the bird as a show bird, is such as might have been expected. You do not say to what variety your bird belongs. When you ask in what class he should be entered, you must bear in mind there are several classes of each distinctive variety. From the description of yours I should say he has more Norwich blood in him than anything else, and he should be entered in the Unevenly-marked class, which includes all birds not coming under the definition Evenly-marked—i.e., marked on each eye, each wing, and each side of the tail, each or all of these marks, but no others. I cannot undertake to put a price on a bird I have not seen, and of which I do not know the pedigree. You must remember that if you send him to a show the price must include the cage in which the bird is exhibited.—W. A. ELKSTON.

RABBIT SCURVY (H. P. W.).—Your Rabbits will be free from the complaint you name if you mix sulphur with sweet oil and apply to the parts affected in the form of a thin paste every four days, which will bring off the scurf, and the hair will soon grow again. Rabbits in confined ill-ventilated hutches are subject to this attack. All hutches should be whitewashed, espe-

cially after containing Rabbits so affected. For this complaint is very infectious, and all Rabbits so troubled should be at once separated from others.

PRESERVING PEAS GREEN (The Gardener).—They may be preserved until the next spring if some of the summer crop are treated as follows:—Pick them when full grown, shell them, dry them gently but thoroughly, and then store them in canvas bags in a dry place. When required for use soak them in water for a few hours until plumped-up, and then boil them. The following mode has been reported to us by a person well qualified to judge of such matters as being very successful:—Carefully shell the peas, then put them in tin canisters, not too large ones; put in a small piece of alum, about the size of a horsebean, to a pint of peas. When the canister is full of peas fill up the interstices with water, and solder-up the lid perfectly air-tight, and boil the canister for about twenty minutes; then remove them to a cool place, and they will be found in January but little inferior to fresh newly-gathered peas. Bottling is not so good—at least, we have not found it so; the air gets in, the liquid turns sour, and the peas acquire a bad taste. What kind of Beans is it that you wish to preserve?

METEOROLOGICAL OBSERVATIONS,

CAMDEN SQUARE, LONDON.

Lat. 51° 32' 40" N.; Long. 0° 8' 0" W.; Altitude 111 feet.

Table with columns: DATE, 9 A.M., IN THE DAY, Baromet. at 29 in. and Sea level, Hygrometer (Dry, Wet), Direction of Wind, Temp. of Soil at 1 ft., Shade Temp. (Max, Min), Radiation Temperature (In sun, On grass), Rain.

REMARKS.

- 6th.—Bright morning, pleasant day; rather oppressive at night.
7th.—Fair but not bright in the morning, very fine day, warm in the afternoon and evening.
8th.—Lazy morning, but fine day; cloudy at night.
9th.—A most beautiful day, very bright with a cool breeze, but there was thunder at 1 P.M.
10th.—Morning fine, afternoon cloudy; rain commencing at 8 P.M., and continuing more or less heavily till the next day.
11th.—Wet and thick morning; fine forenoon and till 5 P.M., when it rained heavily for a short time.
12th.—Morning rather dull, midday fine, but the evening cloudy and rainlike. Excessively heavy shower of short duration on the 11th at 5.15 P.M.; the fall between 5h. 14m. and 5h. 1m. 10s. being 0.05 inch, and therefore upwards of six tons of rain per acre fell in the short period of seventy seconds.—G. J. SYMONS.

COVENT GARDEN MARKET.—AUGUST 13.

The same remarks apply to the markets generally as last week, quotations remaining nearly the same, excepting for Strawberries, which are nearly over. There are but few now to be had, and they are of very indifferent quality.

FRUIT.

Table listing fruit prices: Apples, Apricots, Currants, Currants, Figs, Filberts, Cobs, Gooseberries, Grapes, Lemons, Melons, Mulberries, Nectarines, Oranges, Peaches, Pears, Pine Apples, Plums, Quinces, Raspberries, Strawberries, Walnuts.

VEGETABLES.

Table listing vegetable prices: Artichokes, Asparagus, French, Beans, Beet, Broccoli, Cabbage, Capers, Cauliflower, Celery, Coleworts, Cucumbers, Endive, Fennel, Garlic, Herbs, Horseradish, Leeks, Lettuce, Mushrooms, Mustard, Onions, Parsley, Parsnips, Peas, Potatoes, Kidney, Round, Radishes, Rhubarb, Salsify, Savoys, Scorzoneria, Sea-kale, Shallots, Spinach, Tomatoes, Turneps, Vegetable Marrows.

POULTRY MARKET.—AUGUST 13.

Table listing poultry prices: Large Fowls, Smaller ditto, Chickens, Cackles, Game, Green Geese, Duckings, Pheasants, Partridges, Hares, Rabbits, Wild ditto, Pigeons.

From observations taken near London during forty-three years, the average day temperature of the week is 72.5°; and its night temperature 49.1°. The greatest heat was 89°, on the 25th, 1839; and the lowest cold 31°, on the 26th, 1831. The greatest fall of rain was 1.33 inch.

A SOCIAL GATHERING OF AMATEURS.

[The following, from the pen of our valued correspondent, Rev. William Lea, St. Peter's, Droitwich, is a report of a social gathering of amateur gardeners, who meet annually at his house, and talk over the various subjects in which they are severally interested. They are all gentlemen living in a pretty wide radius of Droitwich, and are almost all known as contributors to the pages of the Journal. Such gatherings as these are productive of much good, and we should be glad to see the example of the worthy Vicar of St. Peter's imitated in other districts.]

We usually meet in the middle of the Strawberry and Rose season, and each guest brings a specimen of his *specialite*, whatever it may be: but this year our meeting was more than a month later than usual, and, consequently, the only Strawberry represented on the table was Dr. Roden's *Fragaria tardissima*, which grows in large clusters like the Hautbois, and certainly deserves its name. But though the Straw-

berries were over, we had the experience of the most abundant season ever known to guide us in the classification of their merits, and as far as I could gather in this district, they would stand in the following position.

First of all comes Dr. Hogg, who seems everywhere to have surpassed himself this year. In 1870 he was magnificent, in 1871 and 1872 a comparative failure, but in 1873 he has come to the front again, and recovered his position as the king of Strawberries, both in size and flavour. The only objection raised against him is, that the second ripening of berries is very inferior to the first in size, and does not possess that peculiar carpet-bag shape, and I might almost say dimension, for which the first is distinguished—in fact they seem to go back to the type of their parent the British Queen. In the same class we were inclined to place Sir J. Paxton, on this soil the handsomest of all Strawberries, and a great bearer; British Queen, La Constante, President, the largest cropper, the hardiest and longest-lived of all; and Dr. Roden's Early Prolific.

The second class would contain rather a longer list of names. At their head would come those old patriarchs Keens' Seedling and the Elton Pine, still hard to beat when the season suits them; Frogmore Late Pine, Trollope's Victoria if the season is not too wet, the Filbert Pine, Sir C. Napier, Stirling Castle Pine, and Reeves' Eclipse, both enormous bearers; Admiral Dundas and Eleanor, both of enormous size. In this list might be added two other well-known varieties, where they will grow—Oscar, which is often fine the first year, but then dies away; and Sir Harry, which on my soil soon runs back to its parent, Hooper's Seedling.

In the third class may be placed such varieties as Black Prince, Marguerite, La Chalonnaise, Rib-man, Cock-comb, and others, which are only worth growing as specimens where the sorts above named succeed; but it does not do to speak positively on this, for no fruit varies so much according to soil and climate as the Strawberry.

I must not, however, omit to mention the Hautbois,

which have been particularly fine this season. I have allowed the old Hautbois, the Royal, the Belle Bordelaise, and the Monstre to run together in one bed, and the result has been very satisfactory.

Now that I am on the subject of Strawberries I will add a bit of gossip, which may be interesting to some of your readers, especially after the letter which appeared in your last number. The general opinion of gardeners is that a Strawberry bed will not last more than three years, some even recommend growing them as annuals. I saw last year a bed fourteen years old which still bears abundant crops, though, as I was told, it has never had a bit of manure given it since its formation. The bed is about an acre in extent, and is on one of the allotments at Dudford, a settlement made by the late Fergus O'Connor. The plants were originally set in rows 3 feet apart, and allowed to run together as they would, till the bed was one mass of Strawberries; then paths were hoed crosswise, so as to give ventilation; then, again, a few years later, in an opposite direction; and so the bed has gone on until now, bearing good crops every year. The soil is a stiff hungry clay, which will bear little else. The varieties grown are Aigburth Seedling and Premier, which on better soils are only third-class varieties, if so much; but they seem to suit the soil, and produce a very profitable crop.

Now for a few words about Roses. On one point all were agreed—that Roses vary according to season, and that the best Rose of one year will seldom hold its position the next. Here, in 1872, La France was the belle of the garden. Next to it I should have placed Dupuy-Jamain, but both are inferior this year, and after the first blooms La France was sadly wanting in freshness. On another point, too, all the rosarians of the party were agreed, that the Roses have been better this year than for many previous seasons. The following names particularly distinguish themselves:—Marchal Niel, Marie Baumann, Alfred Colomb, Mdle. Eugene Verdier, Louis Van Houtte, Pierre Notting, Felix Genero, Duke of Wellington, Climbing Devonensis, Celine Forestier, Boule de Nieve, and three Tea Roses which grow vigorously on the Briar—David Pradel, Niphotos, and Buret. Baroness Rothschild, Countess of Oxford, Therese Levet, and others have not been so good here as in former years, and suffer much from mildew; and of the new Roses there seems to be none which will rank among the first twelve, unless Madame Laeharme and the Perle de Lyon turn out as well as is expected. President Thiers wants substance; Etienne Levet, Madame Bellon, and others are deficient in distinctive character; but Abbe Bramerd and (here) Baron Bonstetten have proved very fine dark Roses, and Coquette des Blanches may prove a better edition of Boule de Nieve. The difficulty of growing fine blooms on this soil (a light loam) is occasioned by the enormous number of buds which are thrown out at the end of every shoot; and even if they are thinned down to one, the plant seems to have exhausted itself in the effort, so that the one left is not so fine or so voluminous in petal as the single bud which a stronger soil will send forth at the

end of the shoot. Perhaps some of your readers may be able to suggest a remedy for this over-productiveness, which has been more remarkable than ever this year.

As our gossips on these occasions are principally on hardy fruits and flowers, I can give no information to that large class of your readers who delight in glass; but on the subject of Plants, it was mentioned that Belle de Louvain is likely to prove a valuable addition; also a local Plum called the Apricot, which is a great bearer, and possesses a most desirable quality—exceeding toughness of wood. The question was raised how far the Pershore Egg Plum is suitable for stocks for grafting other varieties. Some thought it would prove too short-lived, others considered it superior to every other, on account of its great vigour of growth. The Plum crop in this district is but partial, many of the finer sorts having failed altogether, and the damage done by the bullfinches in the winter is visible in the nakedness of the boughs; and apparently where this Charybdis has been avoided, the crop is now in danger of falling into the Scylla of the blackbird's maw. These voracious birds, having finished the Raspberries, Gooseberries, and Mahonia berries, are now turning their attention to the unripe Plums and Apples. The Apple crop is abundant everywhere, and the cordons are very fine; but Pears generally are a failure, with the exception notably of Louise Bonne and a few other sorts.

In addition to our gossip, we had a new scientific treat in a very powerful microscope which was brought by one of the party; under its powerful glasses the mildew on the Rose leaves, which is sadly prevalent this year, was resolved into long cotton wool, but without any signs of life. It was the same with the black blight, with which here and there the Plums leaves are covered. The black covering was resolved into large pieces of slag, and one might have imagined that he was looking at a heap of scoria from a volcano, or from an iron furnace, but still no signs of life. But it was very different when a portion of American blight from an Apple tree was investigated. A formidable and most repulsive-looking monster, about the size of a rat, with claws like a lobster, and covered in a rusty coat of mail, was seen kicking about, evidently in a very vicious temper at having his repose disturbed.—WILLIAM LEA, *St. Peter's, Droitwich.*

CULTURE OF ROCHEA FALCATA.

This is a perfect gem in the class of plants to which it belongs, and when a goodly-sized specimen is obtained and flowered to perfection, its beauties and other qualifications to which it can lay claim are not likely to be soon forgotten. It is a plant, however, that does sometimes disappoint the cultivator, when its healthy appearance leads him to look forward to a successful blooming period, for some of its most vigorous growth will suddenly rot-off at the junction of the leaf with the stem, and such a misfortune will at times overtake it on the stem just above the soil. Again, sometimes the roots will die off suddenly and destroy all hopes of rearing a good plant. These, I think, are the principal ailments to which the plant is liable, and a remedy for them is, I think, to be found in a very careful system of watering at all times, guarding more especially against frequently wetting the leaves, or placing the plant where it receives drip from the glass. A cold and damp atmosphere is against its progress, and an unsuitable soil, as well as careless watering, will create a tendency in the plant to go off at the roots as above stated.

Once when I was a youngster and saw the plant brought to a flower show with its beautiful bloom-trusses protected with wadding and tissue paper, a discussion arose among its many admirers upon the best sort of soil to grow it in. At first they were not very decided, for while one recommended sandy loam and peat in equal proportions, another advised all sandy peat; but it was evident that this particular specimen had a consistent mixture to either of these, and when the exhibitor made his appearance, he gave as his mixture a light, sandy, but not a rarely rich loam, adding one-third of pounded potsherds, and I have grown my plants in a similar mixture and can recommend it. But when I could not obtain light loam, I have used a small portion of mortar rubbish.

Being a fine-rooted plant it may be potted firmly and must be well drained, but it is easily overpotted as well as over-watered; judicious treatment in these matters is one of the secrets of successful culture.

The plant enjoys a light and airy place in the greenhouse near the glass, and ought always to stand on a dry bottom,

and where the water can drain freely from the pot. In winter it must be kept much drier than at any other time. Its principal growing time is from the beginning of the year till July, at which time it flowers and lasts for a considerable time.

After blooming it will throw out several shoots, some of which may be taken off to raise a stock, or if no shoots appear cut a plant down within 2 or 3 inches of the soil, and it will produce numbers of shoots which will strike freely in any situation. I prefer rooting one cutting in a small pot, because then they can be grown on without interruption.—THOMAS RECORD.

PROTECTION FRAMES.

We have these in varied materials; those of recent introduction differing from the old in having earthenware in place of wood, and in parts so as to be easily taken to pieces, and transferred from one crop to another. They may have their uses, but having no experience of them, and being served so well by those old-fashioned ones which we know familiarly as garden frames, I see no reason for change, yet I will not make any ill-natured remarks on these of recent introduction. There is room in our gardens for both. Novelty may endure a time, stability and utility in the end will win.

Passing over garden frames, which are known to all, and their usefulness universally admitted, allow me to draw attention to that class of protectors known as the curate's or ground vineries, and to give some account of the uses to which they may be put throughout the year. I do not know the exact dimensions of the original ones, but ours, as made by our estate joiners, are 4 feet wide. The sides are of 1½-inch red deal, 11 inches deep or high; the roof a span, formed of frames or lights 2 inches thick, each 6 feet long, and both sides easily raised, the lights being hinged to the ridge. The frame is in 12-foot lengths, and so arranged that they join together, and so form any length required. The sashbars are about 1 foot apart, and the glass used is 2½-oz., puttied-in. I am no believer in "jumped joints," nor in glazing without putty. We want to retain as much heat as we can, and keep out as much cold as possible in protectors. By having loose ends we can have the protectors 12 feet, 24 feet, or more in length, as may be wanted, the frames being made with two fixed ends. The frames, to recapitulate, are span-roofed, 4 feet wide, 11 inches high at the sides, and 2 feet 2 inches high in the centre. They are strong, substantial, and are easily moved from one crop to another. This is done in a short time, without liability of breakage.

It should be borne in mind that frames, whilst they protect, at the same time forward the crops they enclose, and this to a considerable extent.

Presuming we have a length of, say, 60 feet, let us see to what purpose it may be put in protecting and forwarding in the course of a season.

In February, as soon as the soil is free of frost, we may place the frame over a bed of Asparagus, with the view of having heads fit to cut three weeks or more before they come-in in the open ground. All we do is to fork over the bed in the usual way, and make the surface fine, then put on the frame; but it is well to give a sprinkling of salt before doing so, for slugs are apt to be active when the heads are appearing, and on these they prey. The lights are kept close, no air is given until the heads appear and are 2 or 3 inches long; then we tilt on the south side about 3 inches day and night when mild, reducing the ventilation if cold, or closing if frosty. The shoots come up strong, and are fit to cut three weeks to a month before these in unprotected beds adjoining, and they are kept on the bed until the cutting in the beds not covered becomes general, when we admit air freely, tilting the lights on both sides, and removing altogether in a few days. The effect on the Asparagus, in addition to its giving heads three weeks earlier, are, that the shoots come up strong, and have fat swollen heads, with which none we have in the other beds can compare. There is as much difference between one and the other as between French and English Asparagus. It is also much more delicate in colour and eating. The fault of our out-door Asparagus early in the season is that it grows, from the cold and changeability of our climate, much too slowly to be tender and good. With the protecting or forwarding frames we secure greater warmth, collect and husband the little sun heat we have; a more equable temperature is attained, and a correspondingly earlier and better produce.

By the close of April or beginning of May, the seasons varying as much as a fortnight in forwardness or backwardness,

the frame will be at liberty, and we can place it over Strawberries, and it will cover two rows, they being in rows 2 feet apart. We placed ours on the Strawberries this year on the 30th of April, and on the 30th of June we had ripe fruit from them, the sort Sir Joseph Paxton, and some of the fruits weighed 1½ lb. It was not until the 15th of July we had the satisfaction of gathering the same variety out-doors from plants in rows adjoining. In this case we have a clear gain of fourteen days. Within a fortnight, or to July 15th, we had in a length of 2½ feet gathered 20 lbs. The fruit was very fine, and swelled-off well. They had air constantly day and night from putting on the frames to ripening, the lights being raised 4 inches on the south side. They had no water, and did not suffer in the least either from drought or heat. I am so well pleased at the result, that protection will be more extensively practised in future. At the time of placing part of the lengths on the Strawberries we put a 36-foot length on a plot of ground fully exposed, and sowed at once with Dwarf Kidney Beans, a row of Canadian Wonder in the centre, and a row on each side of this of Sir Joseph Paxton. To test what difference it would make as between those sown in the frame and those out-doors, I sowed Sir Joseph Paxton in a row about 18 inches from a south wall. Those in the frame, as well as those in the open ground, came up very indifferently—a result, no doubt, of the cold and wet state of the ground. Those in the open ground were all but a failure, the most part of the seed rotting in the ground; enough, however, remained and grew to show the difference in the time of maturing. The frame was kept close, no air whatever being given until the plants formed the seed or first leaves fully, and were showing the true leaves—in fact, these were partly developed before any was given, and then the lights on the south side were tilted 4 inches, and remained so day and night. Only one watering was given, and that when the plants were half grown, or a few days before they were in flower. We commenced to pick from them July 3rd, and had gathered from them 1750 pods from 7 to 9 inches long before those in the open ground were fit to gather, which they were not until the 4th of August. Here, then, we have a clear gain of a month, and not only that, but the pods were double the size and weight of those out-doors. They were sown April 30th. When those in the open ground come in it is evident we can dispense with the frame from the Kidney Beans, and having some strong plants of Cucumbers we may place the frame on rich good ground, and put out the plants in it 6 feet apart, and we shall have some fine fruit in September. The frame may be tilted on the south side a few inches in the hottest part of the day, and be closed early in the afternoon. If we have Tomatoes planted in a row 3 feet apart at the close of May, and the shoots be allowed to lie on the ground and cover a space 4 feet wide, we can place the frame over them when it comes off the Kidney Beans, and have a fine lot of Tomatoes in autumn. They do as well, or better, than those grown against a wall. The Orangefield Tomato is the best for this purpose. With the lights tilted 4 inches on the south side, they will have enough of air. This year, with a temperature out-doors at 90 (we had it that on the 22nd July), neither Kidney Beans nor Cucumbers, with the small amount of air named, were in the least scorched.

About the middle of July, if in the open, or if in a sheltered spot at the end or early in August, we put in three rows of Kidney Beans, so that they may be covered by the frame, which we will put on early in October, and tilt on the south side 4 inches, closing only when frosty, and with mats over the lights if more than 6° of frost; indeed, if the temperature fall to 32°, the protection of mats ought to be given. We shall then have Kidney Beans with certainty up to the middle of November or later. The best kind for this purpose is Sir Joseph Paxton or some other early sort.

At the end of September we plant in a sheltered spot Lettuces from a sowing made early in August, say 1st, in rows, the side rows 6 inches from the sides of the frame, and then 1 foot apart. This will give us four rows, which we will have all the year round; and between these a row each of Commodore Nutt, which may be described as a miniature All the Year Round, very much less, and coming in very much earlier—in fact it hearts in more quickly than any Lettuce I am acquainted with, and may be planted 4 inches apart, and then have good hearts—excellent for salads whole, stripped of its outer leaves. It is a very desirable kind for freezes and for early work, taking up little space. Commodore Nutt will be of first, the frame being placed over the Lettuce in November before any

weather; and with air in mild weather, closing only when frosty, and protecting with straw and mats in severe weather, we have nice Lettuces in winter. Though we sustain less frost, wet and frost, Lettuces are always more in request than early, however well blanched. The frame when it comes off the Lettuce may be placed over another lot of Lettuces from a sowing made the third week in August. Hicks' Cos and Lord's Favorite or the immense Hardy Green are the best for this purpose, placing them in rows 1 foot apart at the beginning of October, the Cos in the centre and the Cabbage kind at the sides. This lot will be in early in spring, in time for the frame to be placed over Strawberries or Kidney Beans; or we may forgo the spring Lettuce, or have extra frames, and put them on the Asparagus beds in January if we give heat, or in February if no heat be used. There is no crop we grow in a garden and which we require to be forwarded, but these frames will bring in a fortnight or three weeks, and in some instances a month earlier than such as have no protection. They only need to be once used to be appreciated, their value and the uses to which they may be put will soon suggest themselves. In another paper I hope to treat of them with heat as afforded by fermenting materials.—G. ARNEY.

NEW METHOD OF PLANTING STRAWBERRY BEDS.

HAVING read of a new method for forming Strawberry beds, I thought I would try it, and it proved a great success. In previous years our crops have been very poor, considering the attention they have had; but this year with the new method we had abundance of fruit. The way in which I planted my bed is as follows:—I did not cut any runners off the old bed, but allowed them to run into a mass. In the autumn I lined strips about 9 inches wide and 2 feet apart through its length, and cut them in squares of 9 inches. These I took up with a spade at 3 inches deep. In the bed prepared for them I had trenches dug 2 feet apart, and placed the squares of Strawberry roots in them, at a distance of 18 inches from each other. The roots were not injured in the least, and the crop was excellent. I had the trenches that were made in the old bed filled with one part well-rotted manure and two parts stiff loam, and the bed was soon covered with plants. Thus, by degrees you can renew the old bed as well as form new ones. Certainly with the old plan of planting single roots we obtained finer specimens of fruit, but unless fruit for show is required, I advise everyone to try the above plan for quantity, and they will not be disappointed.

A market gardener near here, who grows large quantities of Strawberries for sale, mows the tops off as soon as they have done fruiting, covers them up with longish manure, and rakes it off in the spring. This is rather rough treatment, but he always has an immense quantity of fruit.—I. SHELLEWELL.

GARDEN NETTING.

I SHOULD feel greatly obliged if you would kindly allow me, through the medium of your widely circulated paper, to state what I consider to be a piece of right-down cheating with regard to the sale of garden netting.

A short time ago my employer wrote for 100 yards of netting, 4 yards deep—that is to say, 400 square yards, at 1/4 per yard; consequently I, as a matter of course, expected to have as much netting as would cover 100 square yards of ground. The netting came in due course, and the first thing I did after it came was to open it out the entire length and measure it, when I found I had got, as I expected, a piece 100 yards in length. So far so good, but now comes the rub. I had a plot of Gooseberries that I wanted to keep from the birds. The plot is 14 yards wide; so I thought if I cut my 100 yards into 6 lengths, and run them together so as to form one piece, I should have sufficient to cover a piece of ground 22 yards long, by 14 yards wide, and that would be allowing a spare yard for falling over the trees at each end and sides. Well, fancy my disappointment then, when I found it would not cover above half what I had expected it to cover; or, in other words, supposing I had a wall 100 yards long and 4 yards deep, the quantity of netting ordered above would not cover much more than half of it.

Now, I do not profess to know much about buying garden netting, but it seems to me to be anything but fair dealing for a person to advertise and sell netting to cover so much ground, when he knows very well that it will not cover much more than

half of it.—JOSEPH POWELL, *Gardener to Viscount Harberton, Tregunter Park, Talgarth, South Wales.*

THEORY AND PRACTICE OF TREE-PLANTING.

From everything we see and read it is clear that the great part played by evaporation in successful tree-planting is not generally understood, yet on this one thing alone rests failure or success. It makes no difference whether it be winter or summer, there is always moisture escaping. In winter it is from the stems or branchlets, and in summer from these and from the leaves. All this continuous loss of moisture must be immediately made good by root action, or the plant is lost; or the part of the plant which suffers most goes first. It is a popular notion that there is no evaporation in winter. This is a fatal mistake. There is not nearly as much as in summer, but still quite as much in proportion to the activity of the roots.

Now, in transplanting trees, there is but one absolute cause of failure, and that is that the moisture escapes faster than the roots can supply it, and therefore in transplanting, everything we do should be for the encouragement of rapid root-growth, or for the prevention of rapid evaporation until the roots grow.

Of course there are incidental causes of failure. If a tree be badly dug, and half the roots cut away that ought to be on it, it has a worse chance for its life than if properly dug. Or if the roots be allowed to dry, the smaller roots are injured, and only the thicker ones are left to carry on the water work. Still it all amounts to the one thing, which is the moisture dries out of the branches faster than the roots can supply it.

We know how this is in making cuttings, and it is equally true of a tree. We take a piece of stem without roots, but as we know it will wither, we put it in a damp greenhouse, or even cover it with a bell-glass. If we did not it would dry up before the roots appeared. So in out-door cuttings. If we take a large Willow branch and plant it just as it comes from the tree, it will likely die. The sap is escaping from all the small branches, and there are no roots yet to make good the waste. We cannot put a bell-glass over a large Willow branch. If we could it would check the evaporation, and perhaps there would be stronger and better roots for all this top. But not being able to do this we do the same thing in another way. We cut away all the small branches, leaving nothing but a stake or a post, and then it sprouts out like grass on a warm summer's day. Though it has no roots at all, yet such a Willow stake grows better than a Willow tree with all its roots and the numerous twiggy branchlets left on.

This is the lesson for the tree-planter. A tree may, and often does, grow well without any pruning of its tops; but as there is always some injury to its roots, whereby they are prevented from immediately or fully supplying evaporation, a shortening is always beneficial; and this cutting back—sometimes to "bare poles," should always be proportionate to the apparent injury done to the roots, or according to the amount of cold, dry winter wind, or warm, hot spring weather that the plant is liable to encounter.

It will thus be seen that there is a greater risk in winter from fall planting, than in the spring season from planting at that time, if the trees happen to have large heads with numerous branches; but if this matter of evaporation be fully understood, and the tree pruned according to the season, there is no more risk at one season than at another.

This knowledge of the loss of plants by evaporation of their juices can be turned into great practical value in the management of young nursery stock for the winter. If set out in their final places in the fall, they are pretty sure to have either the sap dried out of them, or be drawn out of the earth by the freezing and thawing of the ground. The best way is, therefore, to bury them wholly in earth on the ground, or in the earth that slopes well, so that no stagnant water can be about the roots. One of the best nurserymen we know, who plants out thousands on thousands of young trees every year, and rarely loses one in a million, gets all his young stock in the fall, covers it with earth in this way, and thus has it on hand to work at whatever day suits his purpose in spring. Trees of larger size are also pruned at planting, and we have heard him remark that in his opinion most nurseries which fail in America—and hundreds of new ones annually do fail—mostly do so from their failures to get stock to grow, which need not be, provided they are properly handled.

We believe this firmly, and further that half the trees annually planted die, the majority of which might be saved if only

this thought of evaporation of the moisture were uppermost in the minds of the planters. There is, probably, little new in this chapter to intelligent horticulturists; yet we believe it will be a benefit to thousands, if we are to judge by the losses we see.—(*American Gardener's Monthly.*)

THE BEAUTIFUL AND USEFUL INSECTS OF OUR GARDENS.—No. 8.

BUTTERFLIES, it has been remarked, are like bankers in one particular, their hours of business are mostly from nine to four, or something like that; indeed, there are butterflies one scarcely finds stirring much before 11 A.M., unless the morning be particularly bright; but then again, there is here and there a species, like the Garden White and the Large Heath, that will be on the wing until 6 or 7 P.M. (A sarcastic friend suggests that butterflies and bankers have another point of resemblance, inasmuch as butterflies make no honey, they only avail themselves of that made or acquired by other objects; they cannot claim to be producers, and belong not to the industrial portion of the insect race.) However, it is quite certain that the title of "Children of the Sun" is appropriately applied to these insects, so much do they rejoice in its full rays, with rare exceptions, such as the Ringlet, which seems rather partial to shady places.

"What becomes of the butterflies at night?" said a juvenile querist, who was found, on cross-examination, to be imbued with the notion that there was a fresh emergence every day during the summer, and that those of the previous day died-off. As some older folks have had the same misapprehension, it should be noted that the life of no butterfly is quite so ephemeral as that, extending certainly, even in the case of non-hibernators, to at least a fortnight. At the setting of the sun, or before, butterflies disappear from view in the garden, but it is not at once to sink into a repose which closes their existence. On blades of grass in sheltered corners, on the branches of trees, or on walls and palings, they settle down to await the return of daylight, unless snatched-up by some "early bird." Hence the dusk of evening is not a bad time to look for and "settle" butterflies injurious to our gardens; yet the entomologist is rarely welcome when he obtrudes himself, with the intent of making captures, into the domains of the garden; there is a sort of impression on the mind of the horticulturist that the insect-hunter is likely to leave something behind him rather than diminish materially the enemy's numbers. A great naturalist of our day sorrowfully records a bit of his experience when he was following the swift-winged Colias Hyale in Surrey. "It was here, in market gardens forbidden to the public, that I made her acquaintance. Here were employed a multitude of female Hibernians in the healthful pursuit of horticulture. On one occasion my quarry led me into their midst, when lo! they abandoned their occupation and pursued me with the very same energy I was wasting on the yellow-robed nymph; the scene must have been an exciting one, and would have reminded a classical spectator of Meleager, or Orestes, or *Œdipus* pursued by the Furies: alas! the resemblance to *Œdipus* is greater now!" We will hope not.

The Brimstone (*Rhodocera Rhanni*) is an insect not unfrequent in English gardens, though apparently not an inhabitant of Scotland, and it is noticeable at two periods of the year—in April, and then again in August or September. Being yellow-robed like the fair favourite of the author quoted, it is sometimes confounded with the common and often-annoying Garden Whites, some of which appear at times with a yellowish tinge. But *R. Rhanni* belongs to another family, that of the Red-horns, and a glance at the short and thickened red antennæ at once gives us a marked distinction, and a near examination of the wings in either sex renders it impossible to confound this species with the only white butterfly near its size—viz., *Pieris Brassicæ*. The females of the Brimstone have a palish hue, the colour of all the wings being greenish yellow, while the males are of a brilliant yellow; the differences have been compared to those existent between the two preparations of brimstone known as the "sublimed" and the "precipitated." The most charming speciality in this butterfly is the investiture of long silken hairs, which cover densely the dark thorax, rising to its summit in a sort of crest. When fresh from the chrysalis this butterfly is an active flyer, the spring specimens, after their long hibernation, showing less alertness. It is the males at that season we most usually see in gardens, the females being engaged in depositing eggs.

The eggs are not to be found on any garden plant, but solely, so it is stated, on two species of *Rhamnus*—namely, *R. catharticus* and *Frangula*. I have on various occasions taken the eggs and reared the larvæ to maturity upon the latter plant, and others, like myself, have failed to take the insect off *R. catharticus* near London. But the habit of the species, probably, differs with the locality. The caterpillar is so much the colour of the Buckthorn leaf, that a person may hold one in the hand and yet not detect it, should it be reposing, as they often will, along the midrib. They are of sluggish habit seemingly, and yet feed-up with rapidity in warm weather, say in about five weeks. The wrinkled warted body of the caterpillar, small head, and dull green colour, are strongly suggestive of a relationship to the *Pieridæ*, and the *Rhodoceredæ* do with them form part of that division of our butterflies having cylindrical larvæ. The pupa is totally different from that of the Whites, being singularly humped; it is very carefully secured to a leaf or twig by an anal attachment and a silken band.

One of the boldest of our butterflies is the Painted Lady, also designated *Vanessa Cardui*,* which comes to our gardens during the summer, making cursory visits. Later on in the season its visits are more from necessity than choice, as the garden parterre yields more honey than the scattered wild flowers of autumn. We may see it sometimes hovering about

Vanessa Cardui.

till the end of October, by which time, if not sooner, the chilly nights send it into winter quarters. This insect is unfortunately named, inasmuch as it in no way resembles a "painted lady," and though the pencilling on the under surface of the wings is varied and exceedingly beautiful, it is equalled (Mr. Newman thinks surpassed) by that of the Red Admiral (*Vanessa Atalanta*). On the wing the species is too rapid to be deemed ladylike in its movements; perhaps it may be regarded as feminine in its pertinacity, for if you drive one of these insects off a flower it will come back again, and brave the net; and the same thing occurs even when an individual is settling on a rut in the road. The upper surface of the Painted Lady has a slight resemblance to the Admiral in the forewings, but instead of the well-defined rods and blacks of that species, we have markings more intricate, and of more diversity in colour. In certain years this butterfly is abundant generally, in others it is poorly represented; but there are many places in the south where it occurs every season. To the north of the metropolis, in those rural districts of Middlesex, Herts, and Essex, lying nearest to London, it is, I think, more scarce than formerly; in Kent and Surrey, within sound of St. Paul's, the butterfly has occurred pretty steadily for years past. *V. Cardui* is also one of those butterflies that have a partiality for the coast. The Irish specimens are particularly fine, judging from some I have received, and there the species disports itself high up the mountain sides, as also in some

districts of Scotland. This insect is additionally of interest as being a native of almost every country entomologists have explored.

Though specifically named from the Thistle, *V. Cardui* is also found in the larval state upon Nettles, each individual leading a solitary life, and spinning a few threads, by which it draws the leaves of the food-plant slightly together. The larva is spiny, like those of the *Vanessa*, and it is rather difficult to rear in confinement. Having arrived at maturity (usually in July), it attaches itself by the tail to some projection, and becomes a chrysalis, meriting that appellation, inasmuch as it is really adorned with golden markings.

Just now a lively little fly, whose economy has been already alluded to, is earning itself the thanks of the cultivators of the Cabbage tribe. Its services, to speak in modern phrase, "must be seen to be appreciated." When we consider, also, how eagerly birds of several species pick up the larvæ of *Pieris Brassicæ*, it is a wonder that the caterpillar of this butterfly holds its own from year to year, as we see that it does. My friend Smith thought it very odd, and quite opposed to sound arithmetical calculation, that the larger insect did not disappear before the smaller, since a strong larva of *P. Brassicæ* yields some twenty or thirty flies, which gives a great advantage on the side of the parasite. But, on the other hand, it must be remembered that the parasite has also its insidious enemy, as observed by the Rev. J. G. Wood; and the ichneumon-fly attacking *Microgaster glomeratus* is considerably larger than that species, which gives an advantage to its opponent; only this again is, there is very little doubt, the prey of something else, according to a rather hackneyed couplet which it is not needful to quote. But whereas *M. glomeratus* attacks the butterfly caterpillar, it is evident that the fly parasitic on the former would have difficulty in reaching the larvæ which are snugly nurtured in the caterpillar's body; and we find that this fly accordingly seeks out the cocoons of *M. glomeratus*, and deposits its eggs amongst them.

Observing the number of larvæ which make their way out of the carcase of a single caterpillar of *P. Brassicæ*, one would be apt to suppose that each fly selected one only to receive her brood; but on this point we have not absolute certainty. The weather in some years has much influence on the mutual relations of the ichneumon and the butterfly. Heavy showers just at the time when the female flies should be depositing their eggs probably diminish their numbers materially, while the caterpillars of *Pieris Brassicæ* are tolerably indifferent to any rain which does not entirely submerge them, though more susceptible of cold. Tiny as is this *Microgaster*, and unattractive to the naked eye, the microscope brings some beauty out of it. A recent writer on garden insect remarks, "When this insignificant little creature is placed under the microscope the tiny body shines out in metallic splendour, glittering with an intensity the eye can scarcely bear; and the wings appear in all their beauty, their surface glorious with opalescent hues playing upon them with every change of light, and covered with minute hairs, each of which glitters separately."—J. R. S. C.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 20TH.

This was but a very small show, but to the quality of the Gladioli and Hollyhocks exhibited no exception could be taken.

Of the Gladioli there was a splendid display, though the stands were not numerous. Messrs. Kelway & Son, Langport, Somerset, took the first position in the open class for twenty-four spikes. These consisted of *Horace Vermet*, splendid, Beauty of England, *Timon*, *Porsena*, *Ball of Fire*, intense orange scarlet, feathered with purple; *Damia*, very fine, white and rose; *Madame Desportes*, *Kossini*, *Parsonii*, *Ariane*, *Pictum*, very large; *Clara*, *Numantia*, *Lulbe*, *Lavinia*, *Lady Bridport*, *Pollis*, and five seedlings. Second came Mr. J. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, with an excellent stand, including fourteen seedlings, *Orphee*, *Adolphe Brongniart*, and *Octavie*, fine. Third came Mr. G. Wheeler, Warrminster.

In Class 2, for twelve spikes, the Rev. Lord Hawke, Willingham Rectory, was far ahead of all others with magnificent spikes of *Horace Vermet*, *Lacépède*, *Eugène Scribe*, *Sir W. Hooker*, *Shakespeare*, *Adolphe Brongniart*, *Didon*, *Marie Stuart*, and *Armide*. These were distinguished from those in all the other stands by the great breadth of their segments, as well as by their numerous flowers on a spike. Mr. Douglas was second with excellent spikes of *Legouve*, *Meyerbeer*, and several seedlings.

For six spikes Lord Hawke was again first; the Rev. H. H.

* The accompanying illustration is from Figuier's "Insect World," published by Messrs. Cassell.

Dombraïn second with *Legonvé*, Madame Desportes, and Horace Vernet, fine; and Mr. Douglas third.

For six spikes of Hollyhocks the Rev. Lord Hawke was first with magnificent specimens of *Alba superba*, white; *Talisman*, fine crimson seedling; *Eleanor*, pink; *Queen of Yellows*, sulphur; and *Midnight*, blackish maroon. Mr. W. Chater, Saffron Walden, was second with *Fire King*, crimson; *Purity*, rose; *Whitley King*, bright crimson; *Ethel*, flesh white; *Beacon*, rosy crimson, and *Orange Prince*, salmon buff. Mr. Minchin, The Nurseries, Hook Norton, was third.

The best twenty-four cut blooms came from Mr. W. Chater. In this stand were fine examples of *Golden Drop*, *Bijou*, *Walden King*, *Marion*, *Victor*, *Black Knight*, *Fred. Chater*, *Purity*, *Jessie Dean*, and *Conquest*. Mr. Wheeler, Warminster, was a good second; Mrs. P. Brace, Ossian, *Royal Scarlet*, *Royal Albert*, *Oscar*, and *Gladiator* being noticeable for their size and quality. The third prize was taken by Mr. Minchin. For twelve, the prizes went to Lord Hawke, Mr. Minchin, and Mr. B. Porter, gardener to Mrs. Benham, Isleworth. Lord Hawke had several fine seedlings, and beautiful examples of *Fred. Chater*, *Phryne*, *Alfred Chater*, and *Octavia*.

Cut spikes of *Phloxes* made an effective little display of themselves. Mr. Parker, Exotic Nursery, Tooting, was first, and Messrs. Downie, Laird, & Laing, Stanstead Park, Forest Hill, second, with very fine spikes. The following varieties were especially fine—viz., A. F. Barron, Madame A. Verschaffelt, Madame Antin, splendid colour; Mons. Donneau, Madame Domage, lothair, and Madame la Comtesse de Turenne. Mr. Ware, Hale Farm Nurseries, Tottenham, was third.

Of twelve hardy perennials Mr. Parker sent the only group, comprising fine *Phloxes*, *Delphinium Nahamah*, dark blue, *D. Keteleeri*, *Rudbeckias*, *Helianthus orgyalis*, and other plants. A first prize was awarded.

Of miscellaneous subjects Mr. Ware, of Tottenham, contributed a numerous group of herbaceous *Lobelias*. From Mr. Turner, Royal Nurseries, Slough, came a capital collection of *Dahlias*, for which, as well as Mr. Ware's *Lobelias*, extra prizes were awarded.

Prizes were offered for single dishes of *Apricots*. Moorpark, large and fine, from Mr. Kirtland, Bletchington, Oxon, and Mr. Gardiner, gardener to E. P. Shirley, Esq., Lower Ealington Park, Stratford-on-Avon, was first and second; and excellent fruit of the same kind from Mr. R. Scott, Kidlington, third.

FRUIT COMMITTEE.—Alfred Smee, Esq., F.R.S., in the chair. A Cucumber was received from Mr. J. Munro, Little Heath, Potters Bar, called *Improved Rabley*, a very handsome Cucumber, a foot long, of dark green colour, and with a small white spine. It was highly approved, and as Mr. Munro intends sending it to the September meeting, a decision was left for further information.

Mr. W. Tillery, The Gardens, Welbeck Abbey, sent a dish of *Barrington Peaches*, large and very handsome, to which a cultural commendation was awarded. Mr. Gilbert, of The Gardens, Burghley, sent a dish of *Apricots*. Mr. Bennett, The Gardens, Hatfield, sent a seedling Melon called *Hatfield*, which was not of any merit. Mr. A. Watkins, Bishop Stortford, sent a new hybrid Melon called *Acme*, a large coarse-looking fruit, which was scarcely ripe. Mr. Gallop, The Gardens, Bradford Peverell, Dorchester, sent a new Melon called *Golden Queen*, which had almost become putrid, and another called *Improved Golden* was also very badly flavoured. Mr. Cooling, nurseryman, Bath, sent a seedling Apple of great beauty, of an oblate shape, covered with light crimson, and thickly covered with fawn-coloured spots; the flesh is slightly tinged with red, and is markedly acid, without much flavour. Mr. F. Dancer, of Little Sinton, sent branches of Apple trees grown on the *Paradise* stock, showing the great profusion of fruit borne by these varieties—*Cox's Pomona*, *Cellini*, *Stirling Castle*, and *Small's Admirable*; a letter of thanks was voted to Mr. Dancer.

FLORAL COMMITTEE.—Dr. Denny in the chair. The subjects submitted to the Committee on this occasion were very limited in number. First-class certificates were awarded to Messrs. Kelway, of Langport, for *Gladiolus Hesperia*, orange scarlet, pale purple shaded with white in the lower segments; for *Neogenes*, rose purple with a white band in the upper segments; *Scopas*, pure white, purple throat, broad segments, fine spike; and *Captain Stacey*, orange rose, flaked with purplish maroon, light centre, purple band. *Calyce*, white, in the way of *Madame Desportes*, though not certificated, is excellent. A first-class certificate was awarded to Mr. R. Lord, Old Bottom, Stansfield, for *Picotée Mrs. Lord*, with a heavy rose edge. First-class certificates were also given to Mr. W. Chater, for *Hollyhocks Fire King*, reddish crimson; and Mrs. W. Chater, salmon rose, large and fine; also to Mr. Douglas, gardener to F. Whitbourn, Esq., for *Gladiolus Mary Kinear*. Lord Hawke had first-class certificates for *Hollyhock Vaugnard*, dark purplish crimson, and *Lilac Queen*, two remarkably fine varieties. Mr. W. Bull, of Chelsea, had also a first-class certificate for *Gladiolus Purpureus auratus*, greenish yellow with dark markings in the throat, but

by no means comparable to florists' varieties, though it may give rise to variations.

To Messrs. E. G. Henderson & Son, of St. John's Wood, first-class certificates were given for *Pegonia Prince of Wales*, deep scarlet, and *Prince Teck*, double, light scarlet.

Messrs. Veitch had a first-class certificate for *Aster tanacetifolia*, lilac blue, with ornamentally-cut foliage; and the same firm also exhibited the poisonous *Blumenbachia cordata*, with rather showy orange flowers, likewise fine plants of *Celosia Huttoni*, with very ornamental rose-bronze foliage backed with purple.

From Mr. Eckford, gardener to Earl Radnor, Colehill, came a stand of *Verbenas*, of which *Paradise Williams*, deep rose with a crimson centre, and *Her Majesty*, rose, with a dark crimson eye, were distinguished by first-class certificates.

Mr. McLachlan, Glasgow, had a cultural commendation for a *Cockscorb* called *Glasgow Prize*, of which he showed three specimens with combs measuring from tip to tip 2 feet 9 inches, 3 feet, and 2 feet 9 inches, by 11, 15½, and 17½ inches in breadth, and in colour brilliant deep crimson. A cultural commendation was also given to Mr. Fewell for a handsome specimen of *Adiantum farleyense* 3 feet 8 inches in diameter. Among the other subjects exhibited may be noted a collection of *Hollyhocks* from Messrs. Paul & Son; a golden *Gymnogramma* from Mr. Brown, gardener to Mrs. Alston, Elmdon Hall, Birmingham; some pretty golden *Coluses* from Messrs. Downie & Co., of which *Prince de Scilla* was the best; and two pretty kinds of *Echinops* from Mr. Croucher, gardener to J. Peacock, Esq., Sudbury House, Hammersmith.

THE dates of the Shows of the Royal Horticultural Society for 1874 have been fixed as follows:—Third Wednesday in March, third Wednesday in April, second Wednesday in May, first Wednesday in June, first and third Wednesdays in July, first Wednesday in September, and second Wednesday in November. The Council are to be congratulated on this timely announcement, by which all concerned will be able to make arrangements for the coming year; and we congratulate the exhibitors also, not so much on account of this early notice, as the relief they must feel at the number of shows being reduced from eighteen, as they were this year, to eight. This arrangement will enable the Council greatly to increase the interest and attractiveness of the shows, as well as considerably to augment the amount of the prizes.

As yet no decision has been come to as to the Provincial Show for 1874, and this is in some measure due to no action having as yet been taken by provincial towns. We have heard of several that intend to give an invitation to the Society, but as no intimation has been officially communicated, of course nothing can be done. We would advise those towns which intend to issue an invitation to do so speedily, so that the necessary steps may be taken soon to prepare a schedule, and have the arrangements in some state of advancement, instead of crowding everything into the last few months.

A Committee of exhibitors was appointed yesterday at South Kensington, to confer with a Committee of the Council, and to assist in the preparation of the general schedule for 1874.

EXHIBITION FRAUDS.

[THE following is a letter received by Mr. William Paul, from M. Sisley in reference to the letter on this subject which was published at page 76.]

ALTHOUGH I have not the honour of being known to you, I take the liberty to congratulate you on the noble and independent spirit you have shown in publishing Mr. Walton's letter in THE JOURNAL OF HORTICULTURE. I am quite of your opinion that it is high time that a stop should be put to the fraudulent practices to which horticulture is subject, and I hope that your noble example will be followed, and that the cause of straightforwardness will triumph. I have translated your letter, and have sent it to my friend Carrière, Director of the *Revue Horticole* of Paris, to have it published. I hope that you will approve of the step.

I have since some time attempted to make the same idea prevail for our future exhibitions of the *Circle horticole* Lyonnais, of which I am the Secretary general, but have not yet succeeded. Many of our horticulturists imagine that the frauds serve their commercial interests. I think not.—JEAN SISLEY, Lyons.

RIPENING PEARS.—Besides the common test of ripeness for picking—namely, gently raising the fruit to see if it will readily detach itself at the stem, the specimens may be placed

thinly and evenly on the floor of a cool room, on a blanket previously spread, and then covered with a second blanket. In a short time the effect of the treatment will be apparent in the most golden-coloured Bartletts, and rich, ruddy-looking Seckels imaginable. Pears perfected in this manner rarely have the meanness of their naturally ripened companions; nor do they prematurely decay at the core as when left on the tree.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

GODWINIA GIGAS. *Nat. ord., Aroideæ. Linn., Monœcia Polyandria.*—Native of Chontales mountains of Nicaragua, where it was discovered by Dr. Seemann. "In its native state the tuberous root of *Godwinia* attains a circumference of 2 feet 2 inches, and a weight of 90-92 oz. The petiole reaches 10 feet in height, and has a metallic lustre and mottled surface resembling a snake standing erect, and bears a blade 3 feet 8 inches long. The peduncle is shorter than the petiole, about 5½ feet, and the spathe alone is 2 feet long. The plant grows with great rapidity, and emits a peculiar odour."—(*Bot. Mag., t. 6048.*)

SONERILA BENSONI. *Nat. ord., Melastomaceæ. Linn., Triandria Monogynia.*—Native of Madras Peninsula. Flowers an inch in diameter, bright purple, borne on long red peduncles. "The *Sonerilas* are beautiful plants, inhabitants of humid, cool, shaly mountain regions of India and the Malayan Islands, often growing on mossy rocks and tree trunks. Though easily raised and flowered, they have hitherto proved to be very difficult of continued cultivation, partly no doubt from being kept in too hot and damp a condition, but no less to their soft and succulent stems, which rapidly decay in the winter months, when their vitality is checked by cold or other causes."—(*Ibid., t. 6049.*)

DENDROBIUM LITCHELOBUM. *Nat. ord., Orchidaceæ. Linn., Gynandria Monandria.*—Dr. Lindley, the author of this species, observes that it belongs to the *D. mobile* group, but that besides its different habit, it is a much handsomer plant, with a longer lip and very acute petals and sepals. Its native country was unknown at the date of its publication, and it is not now certain; but judging from the number of forms allied to *D. mobile* that have lately been received from Rungoon, Malmaise, and the Tenasserim provinces, it is most probable that it was imported from thence. Very shortly after Dr. Lindley had published it, it was described as *D. Hanburyanum* by Prof. Reichenbach. "Flowers about 2 inches in diameter; sepals and petals bright purple, reticulated, the latter nearly white at the base; lip 1½ inch long, curved like a trumpet with the mouth upwards; claw white, barred with deep purple; disk deep violet purple bordered with a broad faint yellow band, which is edged with purple."—(*Ibid., t. 6050.*)

SILENE HOOKERI. *Nat. ord., Caryophyllaceæ. Linn., Decandria Trigynia.*—Native of California, where it was first discovered some forty years ago. Flowers 2 to 2½ inches in diameter, pale rose. "*Silene Hookeri* is well adapted for rock-work cultivation; it was introduced by Professor Bolander, who sent seeds to Mr. Thompson, of Ipswich, who forwarded living specimens to Kew, which flowered in May of the present year. The flowers are very fugacious."—(*Ibid., t. 6051.*)

CINCHONA CALISAYA, var. JOSEPHIANA. *Nat. ord., Rubiaceæ. Linn., Pentandria Monogynia.*—Native of Bolivia and Peru. A very distinct-looking form of *Cinchona Calisaya*, probably identical with the *Itzhu Cascarilla* of the Peruvians, which grows abundantly in the same regions as *C. Calisaya*, but in open meadows, not woods, but the bark is of inferior quality. Flowers white, very fragrant.—(*Ibid., t. 6052.*)

MASDEVALLIA VEITCHIANA, IGNEA, LINDENI, HARRYANA, AND TOVARENSIS.—The habit of all these species is very similar. From the root springs up a tuft of oblong, spatulate, leathery leaves, generally obtuse, and tapered into a stalk of moderate length. Among these rise up the taller scapes, each terminated by one or more of the remarkable flowers. In *Masdevallia Veitchiana* the sepals, which form the conspicuous part of the flowers, are of a brilliant orange-scarlet, with a spot, or in some varieties a stripe, of rich crimson-purple, produced by the presence of multitudinous hairs, and yielding a most remarkable contrast; the upper sepal is erect and comparatively broad. In *M. ignea* the sepals are of a fiery-orange, marked with lines of deeper red or crimson, while the upper sepal is projected forwards. In *M. Lindenii* the sepals are of a lovely puce-purple, with a whitish throat, the upper one being nar-

rower and turned backward. In *M. Harryana* the sepals are of a brilliant rosy-magenta, varying in hue, and sometimes, as in the form called *M. Denisoni*, passing into crimson of intense and glowing brilliancy. This species appears to be the most prolific of flowers, and the most charming in colour of any yet introduced. In *M. tovarensis* the flowers are white, the white being of very remarkable purity, and the flowers grow from three to five on a scape. *Masdevallias* should be potted in shallow pots in a compost of fibrous peat, mixed with crocks, charcoal, and coarse sand. The drainage should be very perfect, as they require an abundance of water at the root, and also in the atmosphere. They should be kept near the glass, but out of the sun during summer, and should have as much sun as possible during the rest of the year. The winter temperature should not fall below 40°, nor exceed 60°; while during the summer months they must be kept as cool as possible, consistent with the other requisite conditions. The surface of the soil in which they are grown may with advantage be covered with living sphagnum moss, which not only assists in keeping an equable degree of moisture about the roots, but it is very effective as a set-off to the plants."—(*Florist and Pomologist, 3 s., vi., 169.*)

BARON HILL.

THE SEAT OF SIR RICHARD BULKELEY WILLIAMS BULKELEY, BART.

IN journeying from Bangor to Beaumaris you arrive at the cemetery of the latter town, and on inquiry find that the land was given by Sir Richard Bulkeley; also that most of the houses of the town belong to him. On the hillside above you see a mansion and far-extending noble woods, and these also are his; next you reach Beaumaris Castle, and learn that he is its Constable; further on you pass Fryars, another of his mansions; then you come to the deer park, a walled enclosure, which, with its herd of fallow deer, also belong to the same gentleman; beyond that you reach Penmon Abbey, also having the same proprietor; he is patron of its church, as he is of that of Beaumaris and two others close by; next you arrive at the rabbit warren, also his; crossing that you reach rocks, also his, on which the lighthouse has been raised, and near which the miserable wreck of the *Rothsay Castle* occurred; crossing a narrow strait you reach Puffin Island, also belonging to Sir Richard Bulkeley. In that direction you can travel no further, but if you make a circuit to the westward and inquire who is the proprietor of each farm you pass even to a distance of fifteen miles from Beaumaris, you will find for the most part they belong to him; moreover, he is Mayor of the place. Well, therefore, may he be called "King of Beaumaris," and glad are we in being justified for adding that he and Lady Bulkeley act as good sovereigns should act; and we have great pleasure in aiding to fulfil the Welsh proverb, "The liberal shall not lack praise."

Englishmen of the north, east, and south may be excused for asking for information relative to Sir Richard Bulkeley, and we reply that he quite comes up to the Welsh definition of a gentleman, "a man having a pedigree." The family is of Anglo-Saxon origin, and its name signifies a resident in the bull's meadow (Bul-key-legh), and this is recognised in the family crest, a bull's head. Mr. Nicholas states that they trace their descent from Robert de Bulkeley, Lord of the Manor of Bulkeley in the county of Chester during King John's reign, and that the first who came to Anglesea was William Bulkeley, Esq., appointed Constable of Beaumaris Castle in 1140. From that time to the present they have occupied at various periods the appointments of High Sheriff, Members of Parliament, and in all other ways being leaders of the county. Down to the close of the sixteenth century the family residence was within 100 yards of the church of Beaumaris, and of that residence, known as Hen-plas (the Old Hall), there were until very recently some remains, but now a Presbyterian chapel has taken its place. In 1618 Sir Richard Bulkeley, Knight and first Mayor of Beaumaris, erected a mansion on Baron Hill, and it was not materially altered until 1770, when it was enlarged by the then Viscount Bulkeley, but far greater additions and alterations have been effected by its present possessor. The name, Baron Hill, is a modern form of Bar-on-Hyll, the Bushy Hill.

The woods of noble trees, Beech, Elm, Ash, and Oak crown the hill, and extend along it for miles. Those woods are fronted, and deep passages into them are planted with *Wellingtonia gigantea* and other Conifers and evergreens, so that at no season of the year are they dreary from the absence of

foliage. There are seven entrance lodge-gates to the park, all opening to roads leading to the house, and through or close to those woods.

Those roads, all gracefully winding through the well-kept turf of the park, are open to the public four days in each week—Tuesday, Thursday, Saturday, and Sunday. Visitors to Beaumaris fully appreciate this most pleasant and beneficial privilege, and the townspeople would do the same if they were deprived of it. Other towns struggle hard to obtain a park, and raise monuments, as at Chester, in honour of the man who confers upon them the costly enclosure—for costly it is to keep well furnished and cultivated; in Beaumaris the townspeople have a park entirely gratuitously.

We entered at the lodge gate nearest the woods at the park's northern boundary, and here and throughout a half-mile walk we were surprised as well as pleased with the intense green and vigorous growth of every species of evergreen in the avenue through which we passed, and which crowded on both our right hand and our left, except where, on the latter side, openings are judiciously left to allow of views of the Menai Strait and the Carnarvon mountains beyond. Laurels, Evergreen

Oaks, Portugal Laurels, Conifers, are alike luxuriant and of perfectly balanced growth; the latter character being preserved to them by the high ground and deciduous woods, which shield them from the prevailing and most powerful winds, which here are from the S.W.

Among the Conifers growing by this road and scattered about the grounds are the following, all planted about nineteen or twenty years since—

	ft in.	Girth of trunk at 3 ft. from soil.		Diameter of branches.
		4 ft.	8 in.	38 ft. 0 in.
<i>Pinus excelsa</i>	33 0
<i>ponderosa</i>	45 6	7 9	46 0
<i>anstracia</i>	35 0	5 5	24 0
<i>Abies Morinda</i>	35 0	4 8	26 0
<i>canadensis</i>	24 0	24 0
<i>Cedrus atlantica</i>	32 0	3 0	22 0
<i>Deodara</i>	35 6	25 0
<i>Libani</i>	28 0	34 7
<i>Cryptomeria japonica</i> ..	30 0	28 0
<i>Araneaia imbricata</i> ..	28 0	18 0
<i>Cupressus macrocarpa</i> ..	27 0	20 0
* <i>Wellingtonia gigantea</i> ..	33 0	6 0	17 6

* Planted in 1858 out of a 7-inch pot.

There are also some good specimens of the following—Thu-

jopsis dolabrata, Cupressus Lawsoniana, Thuja gigantea, Picea Pinsapo, P. Nordmanniana, and many others too numerous to mention.

The following are a collection of Hollies, among which are some good specimens—Waterer's Gold, Perado, balearica, Gracier, Handsworthii, Angularia, Marginata, Altaclarensis, Silver Queen, Bronze, Ovata, Donningtoniensis, Myrtifolia, Hodginsii. *Weeping on Stems*.—Yellow-berried, Spinosa, Argentea variegata, and many others.

One Sweet Bay we saw is 35 feet high, and the diameter of the space covered by its branches 20 feet. A Portugal Laurel is 15 feet high, with 20 feet diameter of branches; and a common Laurel 16 feet by 16 feet.

The road by which we entered might be named appropriately the Terrace Road, for terrace it is throughout, carved out of the rocky hillside. Seats for visitors to rest on are fixed at intervals opposite openings admitting views of the scenery; and midway between the lodge and the mansion is a little chapel protecting the sarcophagus of Princess Joan. It is of stone, 4 inches thick, slightly ornamented; is 5 feet 8 inches long, 18 inches wide at the greatest breadth, and 10 inches deep. An inscription placed above it states that it contained the remains of Princess Joan, a natural daughter of

King John, and consort of Prince Llewelyn ap Iorwerth, and that she was interred about the middle of the thirteenth century at Llanfaes Friary, a religious house of Franciscan Friars, founded by her husband about two miles from Baron Hill. After remaining there for nearly two hundred years it was removed and placed in a field hard by, where it served as a watering-trough for cattle. From thence it was removed not many years since by command of the late Lord Bulkeley, who had it placed where it can now be seen. On another slab the following lines are inscribed—

"Blessed be the man whose chaste and classic mind
This unassuming monument designed;
Rescued from vulgar use the sculptur'd stone,
To breathe a moral o'er thy ashes, Joan;
To show mankind how idle is the aim
To thirst for relics, or to strive for fame;
To teach them too to watch life's fleeting day,
Nor grasp at shadows which soon pass away;
For nature tells us in angelic breath,
There's nothing certain in this world but death."

An additional interest attaches to this sarcophagus, because Joan was the mother of the child which, tradition says, was the cause of the death of that greyhound whose place of burial at the foot of Snowdon is so well known at Bed-Gellert. King John had given to Joan's husband that greyhound, whose

correct name was Kil-hart, in allusion to his speed and strength as a deerhound. The prince, returning home and seeing the dog bloody and the child's cradle overturned, hastily plunged his sword through the dog, suspecting him of destroying the child, and then, too late, found the child asleep beneath the bedclothes by the side of a dead wolf. The prince, tradition further adds, founded an abbey at the place now known by the greyhound's name, and the friary at Llanfaes, in gratitude for his child's preservation, and, let us hope, to show his repentance for his hastiness.

Passing on we reached a semicircle of seats, from before which a flight of stone steps descend to the garden, a portion of which is represented in the accompanying engraving from a photograph taken by Mr. J. W. Ambrose, Beaumaris.

The view across this part of the garden extends over a fountain beyond, to the main walk which seems to lead away to the mountain scenery afar off, and is very effective. The beds are tastefully planted, and the growths here are as healthful and luxuriant as elsewhere. The soil being a loam 5 feet deep

resting on a rocky subsoil, added to the sheltered position, sustains the good gardening. We need note but one or two examples. The masses of Pampas Grass are grand, as may be judged from the fact that one mass bore 150 spikes of flowers. A *Pinus macrocarpa* close to them increased its height 5 feet in two years.

In passing away from this beautiful domain we halted to look upon the view, as seen from the terrace in front of the house. With the park and its scattered woodland for the foreground, and the Menai Strait in the mid-distance, beyond rise up the peaked chain of Carnarvonshire mountains, full fifteen miles in a line of which are seen from the Great Orms Head to Penrhyn Castle. At the feet of that range are visible the fields and woods around, as well as the white walls of the houses of Llandudno, Penmaenmawr, and Aber.

Lastly, in close—too close—vicinity we must note the vinery and greenhouses. The two vineries are each 50 feet in length, 14 feet in breadth, and 13 feet in height. The early vinery contains Black Hamburg, Muscat of Alexandria, Black Prince,

BARON HILL.

and Strawberry Vines; the late vinery Black Hamburg and Black Alicante Vines. All of them were models of health and vigour, though they are old, and their size may be appreciated by the fact that on a Muscat of Alexandria there were seventy bunches, averaging certainly 2½ lbs. each, and from which Vine at thinning time two hundred bunches had been cut away. On remarking the cleanliness of the Vine stems and branches, Mr. Gough, the head gardener, said that it was owing to the Gishurst compound with which they were dressed; but we must add, the entirely healthy large leaves and abundant well-coloured Grapes testified to good and well-attended culture.

The greenhouse and plant-house are respectively 69 feet and 51 feet long, which are certainly not half the amount of glazed shelter that is usually allowed for the quantity of plants those two structures have to provide, and we are puzzled in endeavouring to discern how Mr. Gough obtains them. The beds of about twenty acres of dressed ground at Baron Hill, and thirty plants changed every second day for the drawing-room and entrance hall, besides flowering plants for about three-fourths of an acre—all flower-beds—at Nant, have to come from those two houses.

Now we must pass on for a full mile to Fryars, where is the kitchen garden. It is about five acres in extent, surrounded

by a 10-foot wall, and subdivided by other similar walls. The Peach wall, covered with glass, is 270 feet in length. The Cucumber house, in which also are cultivated Melons, Dwarf Kidney Beans, and Strawberries, is 123 feet long, but divided by a glazed partition. This length is required, because Sir Richard Bulkeley wishes for a Cucumber to be on the table every day—whether he gets it we did not inquire, but we saw plants, all vigorous, in various stages of growth, as if there was the effort made to gratify the requirement.

Another glazed range, also 123 feet in length, is devoted to the production of Potatoes, Asparagus, Tomatoes, and other forced vegetables.

The walls are well furnished with Pear, Plum, and Cherry trees, and the crop upon them, perhaps, was just below an average. The kitchen vegetables need no particular notice; but here, as in all other departments, we must express our high estimate of the evidence of Mr. Gough's skill, as we also do of his intelligent courtesy to ourselves. Nant is the flower garden of Baron Hill, but we must endeavour to do justice to it separately.

EVERGREENS APPARENTLY GNAWED.—Like your correspondent "H. E., Hawkehurst," I have been puzzled by what seemed to

be traces of the jaw-work of large larvæ on Rhododendrons, Laurels, and other evergreens. I cannot believe it to be that, nor has observation shown that snails or slugs have to do with it; and as "J. O. W." suggests, it is rather attributable to a decay arising from some morbid condition of the leaves, and hence portions of the leaves are torn away by the agency of rain or wind.—J. R. S. C.

NOTES AND GLEANINGS.

PEOPLE'S GARDEN.—A few minutes' walk from Willesden Junction a limited liability company, which has on its directory the names of Lord Lyttelton, Mr. Harcourt Johnstone, Mr. Solly, Mr. Baxter Langley, and several others connected with the social and intellectual improvement of the masses, have secured some fifty acres of ground, and laid them out after the style of the Crystal Palace park as ornamental grounds, and with all appliances for the performance of athletic exercises. The People's Garden is accessible by train from Broad Street every quarter of an hour, from the Mansion House every half hour, as also from Euston; while the Brighton, South-Western, and Great Western, having running powers into Kensington, render the gardens within the reach of all dwellers on the southern side of the river, and also the west of the metropolis. The flower garden is arranged with borders cut in the grass, and tastefully grown with flowers; the lawns are laid-out for croquet; the exercise ground affords every opportunity for aspirants for fame in aerial tumbling to become proficient in the art; the cricket ground is to be equal to any of those to be found near London; and the platform for dancing, built on 360 piles, is at present the largest in the world. Added to these advantages, which an enterprising board have liberally bestowed, is the natural advantage of a lofty situation, from whence a commanding view is obtained of the counties of Essex, Kent, and Surrey. With these materials at hand the company hopes, by affording gardens and recreation grounds for shareholders and members, to secure for them healthy and rational amusement of an elevating character. A shareholder is made on very easy terms, as the shares are £1-shares, and the amount may be paid either in one sum or at the rate of 1s. 9d. a-month. Shareholders have the privilege of introducing annual members at 5s. each, all of whom have to be balloted for, and so stand a test of respectability. The result of a three-years existence is that the garden is the daily resort of many thousands of persons from all parts of London, but more particularly on Saturdays, Sundays, and Mondays. On Saturday afternoon last the gardens were the scene of a grand horticultural show, at which cottagers, nurserymen, florists, gentlemen's gardeners, and amateurs were invited to exhibit specimens of flowers, fruit, and vegetables in competition for prizes of the value of £40. The Judges on the occasion were Mr. Barron, of the Royal Horticultural Society; Mr. Dean, and Mr. Richards, gardener to Baron Rothschild. The show of different products was highly creditable to the exhibitors; and the fruit and vegetables, coming as they did in many cases from the gardens of the cottager class in the neighbourhood of Willesden and Acton, were an indication of a healthy taste for horticultural pursuits among the working population. The cultivation of such a taste is one of the objects of the People's Garden Company, and they consequently awarded a variety of prizes to the best exhibitors. The button-hole flowers were remarkably successful, and formed very neat and attractive collections. Fruit showed very well. There was also a lovely show of exotics lent by the Royal Horticultural Society. The tent in which they were exhibited was well filled by visitors all day, and no doubt it would have been patronised much longer but for a gale of wind which sprang up about half-past six o'clock and swept the marquee clean from its bearings, burying flowers, fruit, vegetables, and visitors instantaneously in its rums. The visitors were not hurt, but many valuable plants suffered great damage. The gale, however, answered one good purpose: it blew an impending storm swiftly away, and left the many pleasure-seekers to dance in a dry, though cool atmosphere, to the strains of the band of the 1st Middlesex Artillery, till nearly eleven o'clock, when the special train left for Euston.—(Standard.)

— We have the pleasure to confirm the favourable reports of JEE'S PROLIFIC BLACK CURRANT, which have appeared in the pages of some of our contemporaries. Last year we received some of the plants from Mr. Lee, of Clevedon, Somerset, which have this season borne a fair crop of fruit, and we were struck by the tenderness of the flesh and the sweetness of the flavour,

far excelling in both respects those of the old Black Naples, which were growing alongside of them. We strongly recommend this valuable addition to our small fruits to all fruit-growers.

— ONE of the grass gum trees of Australia, XANTHORREA AUSTRALIS, is coming into flower for the first time in Europe, in the succulent house at Kew. There is also a fine plant of AGAVE JACQUINIANA, removed to the Palm house for the sake of space, which is now in full flower.—(Nature.)

— THE sale is announced of the COLLECTION OF AGAVES, FOURCROYAS, AND BEAUCARNEAS belonging to M. De Jonge van Ellemeet, of Oostkapelle, near Middlebourg, in Holland, and which is to take place about the middle of September next.

BEDDING PLANTS IN THE LONDON PARKS.

NO. I.

NEVER have we seen a better display of bedding plants than that which is now to be found in the London parks, and notably in the Green and Hyde Parks; there the beds are gorgeous with flowers and redundant in leafage, where the object sought is leaf-colouring, and the arrangement susceptible of little, if any, improvement. There is necessarily much of dry detail in describing bedding arrangements, and in carrying these out there is a considerable amount of repetition, still it is thought that a few notes on the bedding-out, as exemplified in the London parks, may not be without its utility.

We shall take the Houses of Parliament as our point of departure, and proceed from thence to the Marble Arch. In Palace Yard, near the Victoria Tower, the beds are chiefly filled with Castor-oil plants, Eucalyptus globulus, and Cannas intermixed with Variegated Maize. There is also a fine bed of Solanum macranthum. We now cross St. Margaret's Square adjoining the Abbey by a path, on each side of which is an oblong enclosure, laid out in oblong and circular beds, resplendent in colour in a setting of the brightest of green. We have before had to notice the beauty and softness of the turf, and this year it is in as high condition as it was in the last; there is no brownness, no bare places, but all is smooth, regular, and as nearly uniform in colour as turf can be. There are twelve beds in each enclosure, of which only those at the corners are circular, the rest oblong. All the circles in the northern half are margined with Echeveria secunda glauca, edged with Lobelia pumila grandiflora, forming a dwarf dense mass of blue, and having an inner line of Iresine Lindeni. The oblongs at the sides and ends are margined with Golden Feather Pyrethrum, and edged with Gnaphalium lanatum, forming an excellent setting to the bright masses of Geraniums with which the majority of them are planted. Two of the circles, pairing with each other, are planted with Peach-blossom Silver-variegated Geranium, intermixed with Verbena venosa; other two with Crystal Palace Gem, golden-leaved. In the oblongs are fine masses of Geraniums Lord Palmerston, Editor, Lord Derby, Mrs. Laing, Gaines's Dwarf Calecolaria, and Jean d'Amour Heliotrope. A bed of Murillo Geranium, earmine, is also very fine. On the south side all the circles are margined with Echeveria secunda glauca, and edged with the pretty prostrate Mesembryanthemum cordifolium variegatum, whilst the oblongs have a margin of Blue Bonnet Lobelia, planted intermediately with the graceful white-striped Dactylis glomerata variegata, inside of which is an edging of Iresine Herbstii. Two of the circles at opposite ends are filled with Beauty of Calderdale Bronze Geranium, and other two pairing with each other with Queen of Queens, silver-leaved Geranium, intermixed with Purple Queen Verbena, which far surpasses Purple King in colour. Among the other beds, those of Indian Yellow Geranium, Orange Nosegay, Rubro-cinctum, and Fire King are very good, the last-named especially so. Tom Thumb's Master has run to leaf too much.

In passing through St. James's Park, it may be remarked that a number of Aucubas, Privets, and some Box, the Privets 9 or 10 feet high, have been successfully transplanted to the south side of Stafford House garden on the French system, by raising them by levers; and this having been effected with good balls on the 12th of April, the bushes are now perfectly established, only one or two of the Box trees showing any sign of removal. The site, it may be added, was thoroughly prepared by taking away all the old soil, and replacing it with that thrown out from foundations. On an artificial island in the Serpentine recently formed there is a similar example of successful transplanting, and in this case the trees and shrubs are of larger size.

We next enter the Green Park, and by the side of the path on the east side leading towards Piccadilly, although exposed to the full sweep of our prevailing wind, the south-west, there is a series of oblong beds margined with Blue Lobelia, which in most instances are extremely good. The position is so much exposed that the more tender bedding plants are not trusted in it, but we never saw this portion of the bedding in better condition. Without entering into detail respecting each particular bed, we shall merely signalise a few of the best. Mr. Paul's Bonfire Geranium in particular deserves high and honourable mention, and, though not so good here as elsewhere, is the most effective of its colour—a crimson scarlet. It is plainly distinguishable by its bright glow from a considerable distance. Murillo, deep crimson, is also very fine. Vesuvius, orange scarlet, though it must yield the palm in size and colour to some of the newer varieties, well maintains its reputation as a thoroughly reliable free-blooming kind; and as the season advances, from what we know of it, it will probably be found blooming freely till cut off by frost or distributed to the poorer classes who receive the spoils of the London parks—not, however, as the ill-natured might suggest, as a kind of “black mail” for refraining from appropriation, but to encourage their love of flowers. Here we may observe that throughout the run of beds from Westminster to the Marble Arch, and through Hyde Park to Albert Gate, about two dozen plants would cover the amount of visible abstractions. No doubt this small amount of damage is partly attributable to the careful supervision of the officials and police, but it must be due in much greater measure to the good feeling of the public. A thousand watchers could not secure such a result. Of other beds on this side, Waltham Seedling Geranium, and Albion Cliffs and Daybreak, silver variegated, are noteworthy.

We now come to the north side of the park; running parallel with Piccadilly we find alternately two circular and two oblong beds. These from the east end to Palmerston House are all margined with *Echeveria secunda glauca*, and edged with Purple King Verbena. In this series, beds of Geraniums Excellent, Lucius, Mrs. Laing, and Queen of Queens are the most noticeable. From Palmerston House to Down Street Gate the same margin and edging is continued. An oblong bed in this series filled in the centre with *Coleus Verschaffelti*, surrounded by bands of *Centaurea* is very effective. Among other good beds may be mentioned circles of Queen of Queens, silver-leaved, and Golden Chain Geraniums, and an oblong of *Centaurea* with a centre of *Coleus Verschaffelti Improved*. This is much more glowing in colour than the ordinary form, but we shall have to notice it in still higher colour further on.

From Down Street Gate to the west end of the park the edging is of Sportsman Verbena, but this, probably owing to the trees, is not a success; but there are several good beds of Geraniums, but into these we shall not enter minutely, as we shall have to notice others far surpassing them in our next notice, which will be of Hyde Park.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE operation of sowing now recommended will not admit of much delay, still it will be nearly useless to sow without watering and shading; therefore, if this cannot be conveniently done, the various sowings must remain over till a change of weather take place. Continue to water all the crops that will receive actual injury without it, particularly Celery. *Basil* and *Morjorum* should be cut and dried just as they are coming into flower. Make a sowing of *Carrots* for early spring use on a light, dry piece of ground that is moderately rich. If *Cauliflower* seed was not sown last week it should now be put in, and another sowing should also be made in about a week in favourable situations. The latter sowing will be early enough, no advantage being gained by having the plants very forward before winter. Plant some of the last sowing of *Celery* for spring use, as it will not be necessary to earth it up. They may be planted at a foot apart. Also plant for seed. If *Cucumber* seed was not sown for plants for house culture through the winter, cuttings should be immediately put in to produce plants for that purpose. Those in frames or on ridges will now require an abundance of water. Make a last sowing of *Endive* for spring use. Continue to transplant from former sowings when the weather is favourable. If a sowing of the various sorts of *Lettuces* to stand the winter was made during the past week, another good sowing should be made at the end of the present one. The former will do for transplanting in the autumn, and the latter may remain in the seed bed to be transplanted in the spring. Get ready the materials for making-up *Mushroom* beds next month, clean-out the old beds, and lime-white the walls of the house to destroy

insects and give the whole a clean appearance. Sow seed of Spanish, Tripoli, or Strasburg *Onion* to stand the winter. The Welsh may also be sown for drawing in the spring. The other sorts are best transplanted in the spring for bulbing. The winter crop of *Spinach* should now be sown, if not yet done. We have before recommended the Flanders variety, we wish we could see it in more general cultivation. Sow a small quantity of Cabbage Lettuce with the Spinach.

FRUIT GARDEN.

The bunches of out-door Grapes, to ripen the fruit, might be enclosed in half-globes of glass, which may be obtained at any glass-blowing establishment, and any spare lights of framing or Peach houses might now be profitably fixed against favourite Vines or Peach trees. Where wasps or flies are troublesome the fruit may be defended with gauze or thin bunting, but where much attention in ripening the wood is necessary, nothing is better than covering each fruit very thinly with cotton wadding. The garden engine must be brought into frequent use during the present hot weather. Peach and Nectarine trees should be washed once or twice a-week, and also have an occasional root-watering. Protect all wall fruit from birds where they are numerous. Plums should also be protected from wasps; use bunting or coarse canvas for this purpose, as nets, unless the meshes are considerably less than an inch in diameter, do not afford the necessary protection. Look to the ripening fruits; gather them carefully when ready.

FLOWER GARDEN.

Chrysanthemums must now be layered, either giving them a twist or making an incision up the under side before they are pegged-down. Those intended for the greenhouse may be taken off, and they will sustain no check from removal—that is, if they are gradually severed from the old plants. Give them plenty of liquid manure after they have formed roots. The seed pods of the first blooms of Carnations must now be well watched, and the calyx slit down to avoid the accumulation of wet; it will be a good plan to allow them to hang downwards. Seeds of Pinks must be gathered; half what we have this year saved will be sown immediately, and the other half next June. Shoots slipped-off and dibbled in sand and leaf soil, and kept moist and shaded, will root well. The Tulip bed for next year's planting must be often turned to sweeten by exposure to sun and air. The bulbs, also, may be examined, and any alterations made in the arrangement of the roots according to memoranda made at the blooming time. Discard all bad and inferior kinds, those with foul cups, pointed petals, &c. Auriculars must be kept free from decayed leaves, and the pots regularly supplied with water. Pansy seed may still be sown. Young plants should be pricked-out in beds, as should also any self-sown seedlings worth saving. Train-out the strong-growing shoots of Dahlias, and pull off the deformed buds as they appear.

GREENHOUSE AND CONSERVATORY.

“Shorten the supply of water as the night lengthens” is a good old maxim, and more applicable to the conservatory now than to any other structure, as it is generally occupied at this season with a mixed collection of flowering plants, many of which are probably stove or half-stove sorts, which require but little water in a low temperature. Cinerarias, Violets, Chinese Primroses, Chrysanthemums, and all other plants that will flower this side of Christmas, must be duly attended to, and such annuals as have been proved, to bloom in pots in the spring, should now be sown. Since, however, the practice of forcing flowers in the spring has become general, these annuals have been discarded in many places, as they occupy room where better things can be wintered.

STOVE.

Such plants as will flower this autumn may yet be well supplied with water, and occasionally with liquid manure, but all other stove plants should be watered more sparingly after this time, and it should be performed early in the day. The house may be shut-up early in the afternoon, even with a strong sun heat. At this season, when plants are ripening-off, a high night temperature is not so injurious to them as when they are beginning to grow in spring. In dull weather slight fires may be used in the daytime, so that plenty of air may be given to the plants.

PITS AND FRAMES.

These are now fully occupied with half-hardy plants, which grow freely in such places in the autumn. The lights should be drawn off at night to let in dews, but defend them particularly from heavy showers or continuous rains, at the same time admit large portions of air by tilting the lights at top and bottom. This is a good time to pot Camellias for blooming in the spring, and also to graft them in close frames without artificial heat. Although this is the proper season for propagating some half-hardy plants which are used for bedding-out during the summer, we by no means recommend it to the extent to which it is sometimes carried. Instead of having an immensity of small plants to take care of through the winter, half a dozen old plants of some sorts, and a few more of others, would furnish cuttings to propa-

gate from in the spring for the largest place, and the plants would be found to grow when planted far better than those which had been propagated in the autumn, in consequence of not being stunted, as the whole of their roots would be in a healthy state. Sow the seed of *Pelargoniums* immediately it is gathered, and also that of any other perennial plant, if ripe before the middle of September. Sow *Mignonette* for flowering in the winter.—W. KEANE.

DOINGS OF THE LAST WEEK.

FRUIT AND KITCHEN GARDEN.

In this department we have been keeping the hoe at work, and on walks and borders which could not be readily hoed any weeds were picked out by the hand. Last year we had much trouble in destroying weeds owing to the continued wet; and, probably from a larger proportion of them being allowed to seed than usual, the crops have been full of weeds this year. A great effort should be made early in the season to destroy all weeds, but gardeners cannot work impossibilities, and the press of work in May, through bedding-out and other operations, is apt to cause this department to be neglected.

We find it necessary to look over the Apple and Pear trees about twice a-week to pick off all fruits infested with the maggot. Seven or eight years ago it was very seldom that a sound dish of Apples could be obtained from our garden owing to the *Apple maggot*, now we have very much diminished its numbers. We tried dusting the trees with dry lime just before the buds burst in the spring, but the most effectual remedy is to gather all fruit from the ground daily, and pick off twice a-week any fruit attacked; thus, by preventing breeding, we ultimately get rid of the insect.

We have been potting *Strawberries* from 3-inch into 6-inch pots. Some persons prefer to layer their Strawberry runners in their fruiting pots at once; they fancy it is a saving of time and labour. In potting it is necessary to ram the compost in quite firmly, and not to place the plants deeper in the pots than they were before. The best compost for them is decomposed turfy loam four parts, to which is added one part of rotted manure. After the plants are potted place them in an open position out of doors; a vacant space in the kitchen garden suits them as well as anywhere, and it should be as near water as possible, as they require a good supply when the pots are filled with roots.

FRUIT AND FORCING HOUSES.

Pinerias.—At this season, after the suckers have been potted and the fruiting plants re-arranged, little more is required except attending to watering and ventilation. During hot weather, especially about the end of summer and in autumn, it is desirable to ventilate freely both at the front and back of the house. Shading is seldom necessary at this time of the year; indeed, when Pines are in good health it is as well not to shade them at all, except in a house where the fruit is ripe and ripening. If the fruit at that time is exposed to burning sun it will in all probability be injured. We have a recollection in our early days of injudiciously exposing some Smooth-leaved Cayennes to strong heat and sunshine to forward them for an exhibition, and before the fruit was well ripe it began to decay.

Vinerias.—In the late vinerias the Grapes are very nearly ripe, and here, as in the Pine houses, plenty of ventilation is the rule. If the houses are kept close and dry the Grapes will not colour well. Many of the old gardeners made a rule to withhold water in any shape as soon as the Grapes began to colour. We fancy that damping the paths and border once or twice a-day is beneficial to the Grapes, and causes them to finish-off better.

Cucumbers.—It is now time the plants were put out for the winter supply. For this purpose there is probably no better sort than *Telegraph*, but when the stock is kept-up from seeds it varies considerably. When a good stock is obtained, it is the best way to propagate it from cuttings; this is the only means of keeping it true. Many prefer the black-spined varieties, and one of the best of this type is *Blue Gown*; it is one of the long-fruited sorts, and, consequently, does not bear so many fruits. When in an early stage of their growth see that no insect pests attack them. Red spider is very destructive to *Cucumber* plants, and they will not progress freely if either this or green fly attacks them. Syringing freely twice a-day destroys the first, and fumigating with tobacco destroys the second. Our pits, where the Cucumbers are planted-out, are furnished with pipes for bottom heat, and when the plants are put out we only fill half of the pit with compost, and when that is well filled with roots, in the other half fresh compost is put.

ORCHARD HOUSE.

We have now discontinued syringing the trees, as the largest proportion of the fruit is now ripe, and here as well as in other houses where fruit is ripening, air is admitted night and day. Some of the earliest varieties of *Peaches* were noticed last week as being ripe. Large Early *Mignonne* is a good Peach, but it is, as far as we have observed here, not so good as Early *Grosse*

Mignonne. *Stirling Castle Peach* is very fine this year. It has been more highly coloured than *Royal George* and *Grosse Mignonne* and is very distinct. *Dymond* is an excellent Peach, and has ripened with us this year for the first time in pots. Another new *Nectarine*, raised by Mr. Rivers, has a good crop of fruit, and the colour and flavour are all that can be desired; it is said to be a cross between the *Stanwick* and *Elruge*, and is appropriately named *Stanwick Elruge*. It partakes most of the *Elruge*, and but very little of the *clingstone*; however, it is an excellent sort and can be highly recommended. We are very careful in watering them when the fruit is ripening, as too much or too little will be equally injurious, and will cause the fruit to be wanting in flavour.

CONSERVATORY AND PLANT STOVE.

The plants in the stove have been repotted and re-arranged, giving them plenty of room. No plants should be allowed to crowd each other at any time; in autumn especially, plenty of space should be allowed them. We do not shade so closely now, and in every way give the plants suitable treatment for the time of year. Hardwooded plants require different treatment from the usual occupants of the stove—such as *Orchids*, *Ferns*, and fine-foliaged plants. The latter require shade during hot sunshine, but only when the sun shines; it is bad treatment to allow the shading material to remain on when the day is cloudy. The hardwooded plants should have plenty of sunshine so that the wood may be well ripened, which will cause them to flower well next year.

Liliums are a special feature in the conservatory. This is a class of plants which does not require much attention during their period of growth, and for this reason, as well as for their great beauty, should be cultivated to a large extent. Nearly all of them succeed well grown in pots, and by a little forcing and retarding a succession of bloom can be obtained all through the summer and autumn months. One of the earliest is *L. longiflorum*, with its clear white trumpet-shaped flowers. *L. auratum* in variety will maintain a long succession, as, grown under precisely the same treatment, some of the sorts will be in flower at least six weeks before the later-flowering. Then there is the beautiful *L. lancifolium*—white, red, and rose; and last, though not least, *L. tigrinum*, also in variety. The double variety recently introduced continues in flower a long time, and we have now in flower in the greenhouse *L. tigrinum splendens*, and it is exceedingly effective, its deep orange flowers offering a distinct contrast to the white, rose, and reddish-coloured flowers of the others. Those which have finished flowering we remove to an open space out of doors, and supply sparingly with water until the foliage dies-off, when they are repotted and plunged in some light material out of doors.

Stage Pelargoniums we have cut down, taking cuttings of those we required, and we would say here that all cuttings of this class of plants do best in a cold frame, pit, or on the stage of the greenhouse. We have seen considerable expense and trouble incurred in making a hotbed in which to place the cuttings, when they would have succeeded much better if the frame had been placed on the ground, and the cutting-pots plunged in spent tan, cocoa-nut fibre, &c. I can remember well, when a boy in a provincial nursery, that the nurseryman had a large quantity of stage *Pelargonium* cuttings sent to him, and every one of them was killed through being placed in a hotbed; not from excessive heat, had it been in April or May all of them might have grown, but similar treatment did not suit the matured wood in autumn.

Chrysanthemums now claim a large share of attention. Those who are growing them for exhibition will now be on the alert to "set" their flower-buds; we have been tying and placing sticks to specimen plants, and have removed them to a more open part of the garden. At this season they require all the sun and air possible.

FLOWER GARDEN.

We are now putting in cuttings of all the *Zonal Pelargoniums*, beginning with the *Tricolors* and *Variiegated* sorts. Some persons put in the cuttings in the open ground, where they do well, but it is necessary to lift and pot them before frosts come. We use boxes, as being more convenient, and if through any press of work we cannot pot them when we like, they sustain no injury if left in the boxes till a more convenient season.—J. DOUGLAS.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Books (E. F.).—"The Garden Manual." You can have it post free from our office if you enclose twenty postage stamps with your address. (*Ten-years Subscriber*).—We have a little work now going to press which will exactly suit you. It will be published in three or four weeks.

Rose MILDRE (R. B. P.; and C. B. G.).—The receipt you refer to was given on March 23rd, 1871, and was as follows:—We strongly recommend constant syringing during the growing season with pure rain water, to which has been added a small quantity of soft soap and clear soft water. A strong mixed solution of the latter can be kept in an earthenware pacheon, and

added, when it is settled, to each canful of water, which is used in syringing. This treatment will both invigorate the plants and keep them free from aphid and millew.

MANAGER OF NURSERY (J. Palmer).—As you have a sign-board inscribed, "Palmer's Floral Nursery," and sell the produce, you are not liable to pay for the manager as a servant. He is employed in the trade. Your having another trade to attend to and live by makes no difference.

CUCUMBER DISEASE (A. B. C.).—Your Cucumbers are attacked with the disease for which we know of no cure, except to destroy the plants, and to begin afresh with new soil.

GUM IN CUCUMBERS (Bith).—This is a disease which is more than usually prevalent this season. We have had repeated examples of it sent us, and what we regret most of all is, that we can offer no remedy. It is one of those diseases which, like the Potato murrain, has as yet defied all the skill of science to deal with it.

APPLES (Mrs. C.).—We should not advise you to try Lord Burgheley as a standard in the south of Scotland, but we have no doubt it would do on a wall. Shepherd's Fame is a winter Apple, in use from October to March. You may try Keswick Codlin in addition to Lord Stirling. It is a fine early cooking Apple, and succeeds well as a standard in the south of Scotland.

BUDDING WEEPING ELM, &c. (A Constant Reader).—The end of July is the best time to bud the trees you name, but it may be done now, taking the buds from the shoots that have full-sized fresh leaves, removing the wood. You may practise the budding up to the middle of September.

BRITISH FERNS FROM SPORES (G. H. T.).—Drain some square pans one-third their depth with crocks, large over the holes and finer at top, finishing off with small, on which place a thin layer of moss, then half-an-inch layer of sandy fibrous peat three parts, one part yellow loam, made fine and sifted through a quarter-inch sieve, what remains in the sieve being used for the first layer on the moss, as above stated, an inch thick. Add to three parts of the sifted soil one part of silver sand. Thoroughly mix, and fill the pan to within an inch of the rim, pressing it firm, and making the surface level and smooth, and water through a fine-rosted watering-pot. Let the pans stand three hours, then water again, and when settled scatter the spores on the surface, which may be done by holding the frond with the ripe spores over the pan and gently brushing with the hand. Cover with a square of glass the size of the pan, and set on a damp shelf or other moist bottom in a house safe from frost, as a greenhouse, shading from sun or strong light, and keeping constantly moist. In due course the plants will appear, when the panes of glass may be raised a little on one side by a thin piece of wood, raising it by degrees as the plants advance in growth, and removing it by the time they can well be handled. They may then be potted-off singly in small pots, and if kept close and moist they will soon make good plants.

EXOTIC FERNS FOR EXHIBITION (T. P.).—Of the Ferns you give us to select from, those we should consider most likely to make specimens are *Geiophlebium appendiculatum*, *Asplenium exilis*, *Adiantum emarginatum*, *Asplenium bulbiferum*, *Adiantum assimile*, and *Pteris serrulata cristata*.

VARIOUS (A. G.).—The best time for putting in Laurel cuttings is the last week of September, or from the first fortnight of October to the middle of November. For stretching on wood framework for covering half-hardy plants in winter, use frigidum. The best time to transplant Spruce and Austrian Pine is in moist weather from October to the middle of November, or the first mild weather after the middle of February. Take up the plants of *Azalea pontica*, and pot them for forcing as soon as the leaves have fallen. Pot the Roses at the end of September. After potting Geraniums taken up from the open ground this autumn we do not recommend their being cut-in closely; defer doing so until March. Zonal Geraniums may be distinguished from Nosegays by the former having the petals much broader, more rounded, and in a good variety overlapping, so as to form a circle, the petals being disposed equally around the eye, and the trusses are much smaller. In Nosegays the trusses are large; the three lower petals, though larger, are more rounded than the two upper ones (there being a wide division between them), and not nearly so much so as the upper petals of the Zonals, whilst the two upper petals are narrow and blunt-ended. Take Waltham Seedling as the type of a Nosegay, Clipper or Madame Mazarin as representing the Zonals, and you will soon see the difference. They also differ in the foliage, that of the Zonals being much more rounded and flat.

FUCHSIA TRAINING FOR STANDARDS (Fidjett).—You will not have any chance with standard Fuchsias in competition with those grown as pyramids or bushes, both being examples of good cultivation. The case would be different were the prize offered for standards; then those with stems 2 to 24 feet high could hardly be called standards. Standards should have 4-foot stems. It is natural for the first blooms to be larger than the succeeding flowers, the first should be removed, not allowing the plants to flower until they are well furnished, and the majority of the flowers opening at a time. We cannot undertake to name florists' flowers, they are too numerous and too much alike, and those you sent were wretchedly withered. The thermometer in a greenhouse should be in the shade, or with the face facing north. A temperature of 80 is not too high for Fuchsias in July and August, with air at top and bottom. A temperature of 65 to 75 is, however, more suitable.

POTTING GOLDEN DRAGON PELARGONIUMS, RESINE LINDENI AND COLEUS WINTERING (Edm.).—Lak, up the Pelargoniums at the end of September, removing any soil that will come away freely, and shorten the roots a little; then pot them in a size of pot that will just hold the roots, and place them in a cold frame, keeping them rather close for a few days afterwards, admit air freely. Seven-inch pots would, we think, be large enough. Resine Lindeni and Coleus will strike now in a cold frame kept moist, or any time in September in a gentle hotbed if kept moist and shaded from bright sun. Both are wintered safely in a house with a temperature of not less than 40. They will live in a lower temperature, but not well, and should be kept dry.

LASTANDRA MACRANTHA FLORIBUNDA CULTURE (G. J. R.). We have it now in flower in a stove, in order to succeed well, it requires also a light airy position, but shaded from powerful sun at midday. Like the Peromys and others of their tribe, it is impatient of sudden changes of temperature or moisture, especially when making fresh growth, the leaves wither and fall off at the joints of the shoots; for this we know of no remedy except more careful attention to watering and airing. It will thrive in a greenhouse after the above plan.

PLANTS INHIBITED BY SMOKE OF BRICK-KILNS (L. P.).—There is no doubt that the smoke or vapours of a brick-kiln will drift directly towards your house, though situated at a considerable distance, and if the vapours enter they would seriously damage the plants. We think it likely the injury has been caused by the smoke of the brick-kilns.

SMOKE NUISANCE (G. Mordike).—Use coke, it will heat the flue as well as coal does.

SALAD—ROSE COLLECTION (W. J. W.).—Beetroot and Celery are the ingredients of a salad; but if you wish to exhibit for a prize offered for the best salad, you had better have a greater variety, such as Lettuce, Mustard, and Radishes. "A collection of Roses" is a very vague description. It must be of different varieties, usually not less than twelve. The prize list ought to specify the number, and whether there is to be a single flower or a truss of flowers of each variety.

RHOIODENDRONS, &c. (T. R. H.).—Write to any of the leading nurserymen who advertise in our columns. The one you named could supply all you wish for of every kind, and would advise you honestly. We should return the stamp if you had enclosed one.

TREATMENT OF VINES (St. Brigit).—You ought to have stopped all the side shoots, whether they had bunches showing on them or not. Your house must be very much crowded now; it would, therefore, be desirable to cut back some of the growths to give the wood a chance to ripen, but do not cut too severely. "Practical Treatise on the Grape Vine," by W. Thouson. Blackwood & Sons.

SYRINGING FRUIT TREES (B. B.).—Discontinue syringing a few days before the first fruit ripens; but you should have the trees quite free from red spider at that time, as, if any of this pest should be on the trees, it will spread with amazing rapidity.

BEST SIX EARLY TULIPS (J. A.).—Le Matelas, Proserpine, White Pottebakker, Crayolara, Vermillion Brilliant, and Fabiola.

HERRAGEOUS PLANTS FOR SUMMER BEDDING (A Fifteen-years Subscriber).—The great fault of herbaceous plants is that they do not continue sufficiently long in flower. They are, however, fine in their season. *Agrostemma coronaria* flore-pleno, crimson; *Delphinium Belladonna*, blue; *D. alpeconoides*, blue; *Geranium sanguineum lancastrense*, red; *Lobelia fulgens* St. Clair, scarlet; *Lycnis Haageana superba*, orange; *Mimulus cupreus*, yellowish orange; *Gnothera macrocarpa*, yellow; *O. taraxacifolia*, cream; *Papaver nudicaule*, yellow; and *Silene Schafta*, rosy pink. Why not take off the monotonous aspect by having beds of *Lilium*, *Gladiol*, *Carnations*, *Phloxes*, *Pyrethrums*, *Antirrhinums*, &c.?

ORANGE TREE CASTING ITS FRUIT (A Very Old Subscriber).—The shedding of the fruit is probably due to imperfect fertilisation of the flowers, or it may have arisen from an inactive state of the roots, occasioned by too frequent and heavy waterings having soddened the soil and rendered the roots inactive. The casting of the fruit, if not caused by imperfect fertilisation, generally arises from a check to the roots. See that the drainage is good and the soil sweet.

RE-ARRANGING GARDEN (G. M. F.).—We do not see what more you could have done as regards the preparation of the ground and the stations for the fruit trees, only you say nothing about drainage, and that should be the primary consideration in all improvement of land. We presume it is efficiently drained, or the fruit-tree stations will be only wells for water, in which no fruit tree will thrive. Your walls will answer for Pears, Plums, and Cherries. We should have Pears on the west aspect—viz., Marie Louise, Beurre Diel, and Glou Morceau; Plums on the east aspect—viz., Belgian Purple, Transparent Gage, and Coe's Golden Drop. The other station on the same aspect you may plant with May Duke Cherry, or you may try a *Kaisha* Apricot. The lawn we should have made level, and quite fine on the surface, the ground having been well dug, manured, and firm so as to prevent irregularities afterwards, and then sow in the first moist weather in September the best mixture of lawn grass seeds, which may be had of any respectable seedsman, and roll or beat well with the back of a spade after sowing. It would be well to give a light dressing of manure in November.

PEAS FAILING—PEARS WARTED (J. E. C.).—The Peas were attacked by thrips. The warts resembling the sordida of lichens are exactly analogous to the lenticelles of trees, which is not surprising, as the fruit of the Pear is a continuation of the branch. The white particles which look like fungi are only some of the bleached dignity cells, whose structure is so curious under the microscope.—M. J. B.

TOREA SUPERBA CULTURE (J. H.).—We never saw this with a tall stem. That seen by your employer was probably *Torea hemophyllioides*, which when old, has a stem about 2 feet high. Mr. Williams, a good authority, says of the whole genus:—"In potting, perfect drainage is essential, and good fibrous peat and a portion of silver sand is the best soil that can be used. They grow more rapidly in the tropical fernery in a close case, with an abundance of shade and frequent sprinklings with water over the fronds, and also make fine objects planted in sheltered moist places in the open fernery, but thrive best in the cool house."

SUNFLOWER AND ITS USES (A Constant Reader).—Many facts have been adduced to show that the Sunflower has the property of purifying air laden with marsh miasm, absorbing a great quantity of moist and noxious gases, and exhaling an ozonised oxygen. Moreover, the French Sanitary Commission has lately pointed out that the Sunflower is a most useful plant; it yields about 40 per cent. of good oil, the leaves furnish an excellent fodder, and the stem, being rich in saltpetre and potash, makes a good fuel. The seeds used in small quantities are good for fowls; they are very nourishing.

NAMES OF PLANTS (G. D. M.).—*Melilotus lancastris*. (*E. H. Rodd*).—It is true *Lycopsis arvensis*. The forked cymes are not unusual. (*X. Stumouth*).—*Mandevilla suaveolens*. (*Clare Subscriber*).—1, A *Stachys* of which you have not sent a leaf; 2 and 3, apparently varieties of *Abies excelsa*; 4, *Cupressus Lawsoniana*; 5, *Taxus adpressa*; 6, *Pinus excelsa*. (*Geo. Wall*).—1, *Polygonum aviculare*; 2, *Stachys sylvatica*; 3, *Gnaphalium arvenarium*. (*C. S.*)—No one can determine the names of plants from such scraps.

POULTRY, BEE, AND PIGEON CHRONICLE.

DELAYED INCUBATION.

Mr. J. M. Wain, in a number of the "American Bulletin," cites the case of a hen which left her nest after six days' incubation, and when so discovered "the eggs were very cold." "She (the hen) was certainly off all night, and probably part of the previous day." In this case the certainty (all night) should count for twelve hours, and if we allow for the probability, three hours,

the episode is no improvement upon the Englishman's record of results. The occurrence vouched for by Mr. Wade, exhibited an instance of arrested incubation for about the same number of hours that the eggs were exposed to the cold, as on the twenty-third day (no hour given), but about two days—probably less—behind time) eight out of ten hatched. Mr. Wade did not pretend to set forth with any precision when the eggs were set, at what hour they were hatched, nor how many hours they were deserted. I conclude, therefore, that they were as many hours late as they were hours neglected, for my long and studied experience of just such a question has led me to believe in the exactness of the rule that twenty hours of abandonment does not check even the growth of the chick, provided always that they have native stamina of race, and that the weather is not so killing as to retard vegetation. This may appear a strong and curious assertion to make, but I am fortified by almost a life-long, personal, experimental, and critical experience. Mr. L. Wright, in his "Illustrated Book of Poultry," page 49, relates an incident where the eggs became stone-cold, but fails to observe the time lost, although by treating them with water at 105° they "eventually hatched;" how long after maturity, not stated!

When these circumstances attracted my attention, I would fain have added what knowledge I possessed of the subject, but I preferred to hold my peace—never having preserved the exact details of any of the abundant examples which I have met—until an opportunity should appear of sufficient interest to scrutinise carefully and register with accuracy; for I deem such a question as the one involved devoid of all usefulness if deprived of the minutest particulars of facts. Recently, an event in my yard has afforded me the opportunity, which I need not say I seized, and after this long preamble I will, with your permission, proceed to explain it.

On Saturday, 19th April, 1873, I set a hen at 6 p.m.; the eggs were, therefore, due to hatch on Saturday, May 10th, at 6 p.m., according to ordinary received impression of the period of incubation, which I hold to be more or less inaccurate. On Saturday, 26th April, at 8 p.m., in the dark, she left her nest (having sat just a full week), and could not be found. No hen was procurable that night, and the next day being Sunday nothing was done; but on Monday, 28th April, at 8 p.m., another hen was borrowed, which took to the eggs readily. Having to borrow a hen, the charge of them was not confided to her until darkness had set in. Here then was a loss of forty-eight hours! The second hen sat steadily until Wednesday, 7th May, when, being attacked with diarrhoea, her illness caused her to forsake her nest at 6 a.m. At this time no further endeavour was made to save the eggs, and they remained in the nest until Friday, 9th May, at 3 p.m. (a lapse of fifty-seven hours), when, having two hens come off, I doubled-up the broods, and gave the rejected batch of ten eggs—having discarded three that were added—to one of the two hens, to see what sort of business she could make of the trial. Bear in mind that the sum of the time during which the eggs were uncovered, uncared for, and untreated to any application of heat, was 105 hours! Now let one take from that, twenty hours, as the time in which I think chicks suffer no loss in growth, and I obtain eighty-five hours as the period to be made up by extra incubation; and that this estimate was not incorrect the result shows, as on Tuesday, 13th May, at 6 a.m., eighty-four hours after due, all the eggs with one exception hatched out strong and healthy chickens. Here was an arrest of incubation of eighty-four hours, although the eggs had been unprotected during 105 hours. This may appear incredible, but to prove the calculation, and to render it more extraordinary still, let me allude to the fact that twenty-one days or 504 hours are usually allowed for incubation, whilst in the case now instanced the eggs were only under the hen 460 hours! Leaving forty-four hours to be accounted for between 504 hours the stereotyped quantum for incubation, and 460 hours in which these neglected eggs were delivered of full-grown chicks. I think this proves both of my ideas (1st) that a chick will grow for twenty hours or so after being deserted in the shell, and (2nd) that the natural and sufficient period for incubation is twenty days. For add twenty hours of growth to 460 hours (the time when the eggs were actually under the hens), and there are 480 hours in all. Now take twenty-four hours from 504 (being twenty days instead of twenty-one), and there is the proof—480 hours. If I am asked why this should be, that eggs can pass through so many shocks and chills, I can only say I know not any reason for it. But this I know, that out of thirteen eggs I received ten lively chicks, which it took three hens to hatch, and that the three only sat altogether 460 hours, or twenty hours less than twenty days. If it proves anything at all, it is that close sitting kills; that a chick will grow twenty hours after it is left alone, and that twenty days are sufficient to hatch chickens if the mother hen is not too ardent an incubator. Upon general principles, then, I would recommend that every chance should be given before a clutch of valuable eggs be abandoned. If by the feel it is ascertained that there are chicks within, wait until the discoloration of the shell announces the fact of decomposition having begun.

I may add that the egg I said was not hatched had within it a live chick, in whose behalf I performed a Cæsarean operation, by taking it out of the shell. At first it showed great weakness, but soon came round under the influence of a spirit lamp and cotton batting, and it, and all the others of the belated brood, are as thriving and active as any in my possession, and I am apt to fancy that they are more vigorous, which may be only partiality. Up to this time not one has died.—R., *Tarrytown-on-Hudson*.—(*American Pet-stock Bulletin*.)

BRAHMAS' COMBS.

THE forward position of Brahmas' combs, noticed by Mr. J. R. Croker, is not peculiar to them alone, as the combs of pure-bred Malays are placed similarly, which, together with the fact that a cross between the Malay and a single-combed breed of fowl produces triple combs (a matter that I have never seen mentioned, but of which I have much experience), warrants the supposition that Brahmas are a well-established cross between Malays and Cochins.—O. P. H. Z.

HAS Mr. Croker compared the comb of the Brahma with that of the Malay? I am inclined to think that he will find the "distinctive feature" he points out in the Malay. The Brahma is a good useful fowl, but I feel sure it is a mongrel having Malay blood in it.

More than twenty years ago I produced the pea comb by crossing a Malay hen with a Dorking cock. Three chickens out of nine had the pea comb, and one was combed like a Light Brahma. Besides, in some American book on poultry, I think Bennett's, the history of the production of the Brahma is given, showing that it was produced in America by certain crosses made there.—R. B. P.

PUBLISHING JUDGES' NAMES.

I FULLY endorse all that has been said by Mr. Wren in last week's Journal. It ought to be imperative on every Committee to publish in the schedule the names of the judges. My experience as an exhibitor and breeder of some years' standing, teaches me that it is only fair to all to publish the names of the judges. As you say, the secretary's name, and the names of the patrons, president, and committee are published, why not the name of the judge? He is the most important officer in the show. It is easy to see in many cases why it happens thus—the judge may have only a very meagre knowledge of fowls, and yet because he is a friend of some of the gentlemen belonging to the show, or because he has been judging at some other show, they invite him.

An objection raised to this mode of procedure is, that if the name of the judge is known good exhibitors will not show when a man is judging whom they may think incapable of judging, and very right too. Would any man who understands what are good birds send his best specimens to what he may term a lottery? for sending them to be estimated by some judges is nothing more. I and other exhibitors have decided not to show if the names of the judges be not published. Would it not be much better for a society to engage a thoroughly competent judge? and if financial difficulties did present themselves, I am sure no exhibitor would object to paying 6*l.* extra for the entrance fee. If they would do this they would find it advantageous. Shows are often ruined on this account, especially local shows, for a local show and a local judge are a farce. How often do we see a class limited to two entries because a local judge knows all the birds in the district.—G. H. PICKERING, *Middle Street, Driffield*.

HETTON POULTRY, PIGEON, AND RABBIT SHOW.

THE above-named Show was held on Tuesday the 12th inst. in the Hetton Hall grounds, than which a more suitable or more attractive place could not be found. The poultry were arranged in the old-fashioned box pens in double tier in the lower portion of the meadow, and for the amount given in prizes the entries were very good, but in the absence of a catalogue we are not able to give a correct list of the winners.

In most of the adult classes there were very good birds, the *Spanish* being a fair lot, and the *Dorkings* very good. The *Cochins* were poor, but *Brahmas* very good, and all the *Hamburghs* noteworthy. The winners in the above classes were mostly Messrs. Buglass, Clarke, Proud, Whitfield, and Moor. In large Game Messrs. Robson had it almost to themselves with good birds; while in Game *Bantams* Mr. Hunter stood well with some stylish birds, Mr. Laing, of Sunderland, taking the chief prizes in *Ducks*. In chickens the Brahmas were forward and good, and the Red Game chickens exceeding fine in all particulars, while the Game Bantam chickens of that colour were the best class in the Show. The principal prizes in this were won by Messrs. Robson and Hunter. The winners in *Polands* were Golden, and very forward and promising birds.

Pigeons were poor, with the exception of English Owls, but,

on the contrary, the Rabbits were good. A large cage of young Lops contained some most promising animals.

The Judge was Mr. E. Hutton, Pudsey.

PADDOCK POULTRY SHOW.

This was held on the 16th inst. The following are the awards:—

- BRAHMAS.—1, H. Beldon, Goltstock. 2, J. Bail y, Earby.
- HAMBURGHS.—*Golden-spangled*.—1, H. Beldon. 2, G. Haigh, Holmfirth.
- Silver-spangled*.—1, H. Beldon. 2, J. Robinson, Garstang. *Golden-pencilled*.—1, H. Beldon. 2, J. Robinson. *Silver-pencilled*.—1, H. Beldon. 2, J. Robinson.
- BLACK.—1, N. Marler, Denton. 2, H. Beldon.
- GAME.—1, H. Beldon. 2, J. C. Brooke, Holmfirth.
- BANTAMS.—1 and 2, G. Nobles, Staincliffe. 3, T. Cropper, Bacup.
- SPANISH.—1, J. Powell, Bradford. 2, H. Beldon.
- POLANDS.—1, J. Robinson. 2, S. H. Wood, Diggle.
- COCHIN-CHINA.—1, H. Beldon. 2, T. F. Anstet, St. Helens.
- DORRINGS.—1, J. Robinson. 2, J. Walker, Rochdale.
- HOUZANS.—1 and 2, J. W. Hibbert, Hyde.
- GEES.—1, J. Walker. 2, J. Crossland, Royds Mount.
- DUCKS.—*White Aylesbury*.—1, J. Walker. 2, H. Hutchinson, Littleborough.
- ROUEN.—1, J. Newton, Salsden. 2, J. Walker.
- TURKEYS.—1, J. Walker, Rochdale.

PIGEONS.

- CARRIERS.—1 and 2, G. J. Taylor, Farnlow.
- CROPPERS OR POUTERS.—1 and 2, G. J. Taylor.
- TRUMPETERS.—1 and 2, W. Harvey, Sheffield.
- TUMBLERS.—*Almonds*.—1, G. J. Taylor. 2, W. Harvey. *Any variety*.—1 and 2, G. J. Taylor.
- FANTAILS.—1, W. Tomlinson, Newark. 2, J. F. Loversedge, Newark.
- BARBS.—1 and 2, G. J. Taylor.
- TURBATS.—1 and 2, G. J. Taylor.
- JACOBS.—1, G. J. Taylor. 2, W. Harvey.
- ANY OTHER VARIETY OR COMMON.—1 and 2, G. J. Taylor. c, J. Thresh, Bradford.

RABBITS.

- HIMALAYAN.—*Buck*.—1 and 2, S. Ball, Bradford. *Doc*.—1, S. Ball. 2, J. Hallas, Huddersfield.
- ANGORA.—*Buck*.—1, S. Ball. 2, T. Gurnes, Northampton. *Doc*.—1, H. Cox, Wobley. 2, G. C. Hutton, Bradford.
- LOPE-EARED.—1, G. J. Taylor. *Prize for the Unimproved Rabbit on the field*. F. Banks, London. 2, J. Hume, York. *Doc*.—1, F. Banks. 2, A. H. Easton, Hull.
- SILVER-GREY.—*Buck*.—1, A. H. Easton. 2, S. Ball.
- COMMON.—*Buck*.—1, J. Hallas, Huddersfield. 2, F. Berry, Mirfield. *Doc*.—1, A. Haigh, Longroyd Bridge. 2, J. Hallas.
- ANY OTHER VARIETY.—1, G. R. & K. Hackett, London. 2, F. Banks.

CATS.

- PERSIAN.—1, W. Appleton. 2, J. Dvson, Paddock.
- MANX.—1, B. Helliwell, Delph. 2, D. Horne, Luckwood.
- TORT-OISELLE OR TORT-OISELLE-LAND-WHITE.—1, R. Spivey, Huddersfield. 2, J. Binns, Lindley.
- BLACK.—1, A. Thornton, Mosley. 2, R. Shawcross, Oldham.
- GREY TABBY.—1, J. Henrich, Huddersfield. 2, J. Hampshire, Liversedge.
- JUDGES.—*Poultry*: Mr. J. Jordan, Dalton, and Mr. R. Lane, of Birmingham. *Rabbits and Cats*: Mr. Fisher, of Crosshills, near Skipton, and Mr. G. Johnson, Kettering.

MALMESBURY POULTRY AND PIGEON SHOW.

CONSIDERING the inconvenience there is in arriving at this small town, there being no railway within five miles, the Committee must be heartily congratulated on the success of the Show held on the 14th inst. Birds came even from Worcester, Oxford, and Basingstoke.

The chief features in the poultry classes were *Game* fowls. Black Reds were very good, this year's birds taking first honours. Light *Brahmas* and *Cochins* were exceedingly good, and fairly surprised the rustics of the neighbourhood. *Bantams* were very good, Black Reds taking first, a handsome pen of this year's Duckwings being second. Rouen *Ducks* and the Black East Indian were all that could be desired.

In *Pigeons*, Pouters were the chief feature, two pairs of grand White birds taking the first and second prizes. Trumpeters and Jacobs were good, though only two pens of the latter were shown. Antwerps were very strong and good. The class for Any other variety brought forth some really good birds, a pair of really handsome Pygmy Pouters being first, and Yellow Barbs second.

- DORRINGS.—1, E. Hooper, Calce. 2, C. Cole, Malmesbury.
- SPANISH.—1, W. Holston, Bristol. 2, W. Hanks, Somerford Magna.
- GAME.—*Black-breasted Red*.—1 and 2, F. S. Godsall, Stroud. *hc*, E. Bowly, Worcester. G. Hanks, Malmesbury. *Any other colour*.—1, E. Witwood, Worcester. 2, E. F. Woodman, Cirencester. *hc*, J. Andrews, Worcester; E. Bowly.
- COCHINS.—1, S. Beckland, Crutwell. 2, J. S. Maggs, Tetbury. c, Rev. N. J. Ridley, Newbury.
- BRAHMAS.—*Dark*.—1, J. Prinder, Cirencester. 2, E. S. Godsall. *hc*, T. Jones, Malmesbury. *Light*.—1, Mrs. Sterne, Devizes. 2, W. Hanks. *hc*, G. Ellison, London; W. Latham, Wotton Bassett; Rev. N. J. Ridley.
- HAMBURG.—1, H. Thompson, Highworth. 2, J. S. Maggs. *hc*, R. Barrett, Stroud. c, G. Day, Somerford.
- ANT OTTER VARIETY.—1, J. Binton, Warminster. 2, J. Archer, Wotton Bassett. *hc*, Mrs. Sterne; Rev. N. J. Ridley; J. S. Maggs.
- GAME BANTAMS.—1, E. Bowly. 2, G. Holloway, jun., Stroud. *hc*, E. Bowly; C. Scamling, Trowbridge; S. Tilling, Malmesbury.
- BANTAMS.—2, W. Garnham, Lasborough.
- TURKEY.—1, Rev. N. J. Ridley. 2, S. Gibbs, Somerford Magna.
- GEES.—1, G. Cole. 2, G. Hanks.
- DUCKS.—*Rouen*.—1, G. Holloway, Stroud. 2, T. Jones. *Aylesbury*.—1 and 2, J. S. Maggs. *hc*, G. Hanks.
- ANY OTHER VARIETY.—1 and 2, G. S. Sainsbury, Devizes. *hc*, C. Cole.

PIGEONS.

- CARRIERS.—1 and 2, T. Jones, Malmesbury. *hc*, W. Tomlinson, Oxford.
- POUTERS.—1, R. Barrett. 2, G. Holloway. *hc*, H. C. Howard.
- TUMBLERS.—1, R. Barrett. 2, T. Jones. *hc*, W. Hodgson, Bristol.
- TRUMPETERS.—1, A. P. Maurice, Basingstoke. 2, S. Beckland, Crutwell.

- ANTWERPS.—1 and 2, W. Tomlinson. *hc*, R. Barrett, jun., Stroud; J. S. Maggs.
- JACOBS.—1, G. Holloway.
- FANTAILS.—1, Dr. Hunter, Malmesbury. 2, W. Holston. *hc*, R. Barrett.
- ANY OTHER VARIETY.—1, G. Holloway (Pygmy Pouters). 2, W. Tomlinson (Barbs). *hc*, W. Tomlinson (Barbs); R. Barrett (Dragoons); W. Hodgson (Nuns); J. S. Maggs (Barbs); J. P. Salway (Turbits).

- RABBITS.—*Lop-ear*.—1 and 2, C. Arthur, Melksham. *Himalayan*.—1 and 2, C. Arthur. *Silver-Gray*.—1, C. Arthur. *Any other variety*.—1, C. Arthur. 2, A. Bailey, Malmesbury.

Mr. Martin, of Worcester, was the Judge.

POLYGAMY IN PIGEONS.

PIGEONS, say the various treatises, are strictly monogamous; and the rule thus positively stated I have hitherto regarded as being one which did not admit of an exception. There is, of course, the well-known proverb that there is no rule without an exception, but as regards the monogamous nature of Pigeons I have never until this year met with an illustration of the truth of the proverb.

I do not attempt to speak of the experience of other Pigeon fanciers in the matter; but my own experience has been that although, if they have not been properly mated, two birds will sometimes "break pair," as it is said, and each bird take to itself a new partner of the opposite sex, the male bird of a pair properly mated will not associate himself with a second female partner and at the same time continue to consort with the hen with which he was first mated. Such, I say, has hitherto been my experience; but I have this season met with what I believe to be a remarkable exception to the rule in question, and as a statement of the facts may interest some of the readers of "our Journal," I will endeavour to give a short account of the case.

I may begin, then, by saying that I became possessed a short time since of two pairs of Tumbler Pigeons, one a pair of Black Shortfaced, and the other a pair of Blue Long-faced Tumblers. These two pairs of birds were placed together in the same house, but apart from all other Pigeons. They had not been more than a very few days together when I observed that the Black hen took but little notice of the invitations made to her by her own partner to enter a nest, whilst she seemed much attracted by the attention shown to her by the Blue cock. This state of affairs was immediately followed by the Blue cock altogether beating-off the Black one from the companionship of his hen, and by his driving both hens to nest most persistently. In a very few days two nests were made in two separate corners of the house, and a pair of eggs was laid in each nest. Both hens commenced sitting, and during the period of incubation I believe that the Blue cock regularly took his turn on each nest, for I repeatedly saw him sitting first on one nest, and then on the other. I should mention that from the time when the two hens were first taken charge of by this bird, I have never seen the other bird either approach his own hen or attempt to enter her nest, nor have I ever seen him attempt to pair with the Blue hen, so there cannot have been a change of partners.

Now for the hatching. The eggs laid by the Blue hen were, during my temporary absence from home, injured by some means; but I ascertained by an examination of them that each contained a bird. From the eggs laid by the Black hen two birds were hatched, which lived until they were about three weeks old. Both birds were Blue, so that their parentage on the male side may be regarded as fully established. The cohabitation of the one cock bird with the two hens did not, however, end here, but has continued down to the present time. Somewhat more than three weeks ago the two hens again went to nest, each, again, sitting on a pair of eggs. On this occasion as on the former, the Blue cock has, I believe, regularly taken his turn of sitting on both nests. All the eggs, too, have again proved fertile, two young birds having been hatched from each pair of eggs. One pair of these young birds I have been under the necessity of shifting to the care of nurses, a circumstance which I regret, as I should have been glad to have observed how the one cock bird would have managed with the two pairs of young ones claiming his attention at the same time. The foregoing is, as I have already indicated, the only case of the kind that has come under my observation in any way; but perhaps other readers of the Journal will state what their experience has been.—R. W.

HONEY HARVEST IN DUMFRIESSHIRE.

THE honey harvest in the clover districts of Dumfriesshire, which have no heath in their vicinity, has now been gathered, and the result in a great measure corresponds with that recorded by your esteemed correspondent, "B. & W." The bee season of 1873 is the worst that has been experienced since 1855, which was only a shade better than 1853 and 1851. There is no surplus honey. All efforts to get supers stored with sweets failed. In every case they were appropriated by the queen to breeding purposes. When the spoiled combs were cut out and new ones built they were again filled with brood. But I am not disposed to think that either "sourness of soil" or "winter rains" have

operated at all against the secretion of honey, for whenever a fine day occurred it was found in abundance.

The season opened with the fairest prospects. On the 20th of May the best stocks were at the verge of starvation, but by the 8th of June they were filled to overflowing. Not one empty cell was to be seen. After that date, however, no addition could be made to their stores. Damp showery weather set in, and has continued up to the date at which I write (August 11th). This alone may explain our disappointment, for if the products in the nectaries of flowers were washed-out by heavy rains, or much diluted with water, the labours of the bees will be vain. To have honey of good quality, and to permit of its being successfully gathered, the atmosphere must be so dry as to cause evaporation. So long as the flowers are wet with dew or atmospheric moisture pollen may be collected, but comparatively little honey will be carried into the hives. With the exception of some five or six days which occurred at intervals, the last nine weeks have been damp throughout. Breeding stocks have, in consequence, been obliged to draw largely upon their stores, but those from which fertile queens were from time to time removed are in very good condition. These latter, having little brood to maintain, were just able to earn a subsistence and continue their *status quo*.—R. S.

HORSERADISH.—Very few people know that pieces of horseradish added to the vine jar in pickles improves their flavour and prevents mould.

OUR LETTER BOX.

BLACKPOOL POETRY SNOW (*H. B. Smith and Others*).—You are quite justified in complaining that there were no pens, and the birds had to be shown in the baskets they travelled in. It was probably intended to be a makeshift affair, as it was not advertised.

POULTRY-KEEPING (*L. M. N. P.*).—We did not see the pamphlet you refer to. We believe that we made our extracts from the provincial paper of the county where the speech was delivered.

FOWLS INJURED BEFORE REACHING THE SHOW (*H. Moore*).—We would publish full particulars if they would prevent similar malpractices. As your birds were highly commended, notwithstanding their feathers had been clipped off, it is doubly annoying. It is an additional evidence that the travelling baskets should be locked, the key being sent to the secretary by post.

FEEDING POULTRY AND OTHER BIRDS (*B. S.*).—All live food has a tendency to make birds thin, and to render them dissatisfied with other food. We advise you to discontinue the beetles, except now and then a few thrown down. Wherever they constitute the daily food we should look for a great mortality, and we do not in any case recommend them. The real use of live food is in rearing or "meating-off" certain birds. There is sometimes a critical period in the life of a young Pheasant when it will eat nothing in the way of ordinary food. It has become dissatisfied and wanders about hungry in the midst of plenty, crying, Peep, peep, peep. At these times only ant's eggs, or live food in the shape of maggots will save them. Another case where live food is required, is when it is necessary to get a recently caught Nightingale to feed. The food is scraped beef mixed with yolk of egg. The trough inside the cage is filled with this, and a meal-worm is half buried in it. The upper half writhing and twisting about attracts the bird. It pulls out the worm, and in eating it it eats some of the food adhering to it. The worm is buried deeper every day, thus giving more of the food, and at last it is discontinued. Those, however, who keep Nightingales in cages, know that at certain times appetite has to be renewed by the gift of a few meal-worms. It is not so with fowls, but with many birds the live food is always held as a valuable last resource, and is used for that only.

POULTRY IN NEW ZEALAND (*D. Z.*).—There are plenty of pure fowls in New Zealand, and more are being sent out. We cannot help thinking eggs may reach as far in condition for sitting, but our experience is unfavourable to the belief. The best means of conveyance is a steamer. We cannot at present quote the exact cost of transit, but it is not much. The tank should be tin or zinc.

PROLIFIC TURKEY (*W. B.*).—Your hen Turkey, which has produced eighty eggs, has laid far more than the usual number. Has she never been broody?

AYLESBURY DUCKS' PLUMAGE YELLOW (*Ignoramus*).—We have no doubt the plumage of the Ducks is affected by the dirty water of the pond, especially if yard and stable drainage runs into it. Keep them from it, and let them run in the highest grass you have while the dew is upon it early in the morning.

BRAHMAS BROODY (*Constant Reader*).—We have kept Brahmas ever since they were first known. We do not find they are more prone to be broody than other breeds. We should be very sorry to cure them of it. If you want fowls that do not sit you have plenty to choose from—Spanish, Hamburgs, Creve-Coeurs, Houdans, and La Fleche. No fowl desires to sit till it has laid its eggs. We have hundreds of Brahmas, and go for weeks (to our cost) in the early spring without a broody hen.

PIGEONS (*Fan*).—The varieties you name are alike in hardness. If you refer to our present number you will see an advertisement from Mr. Fulton, Union Terrace, Brockley Road, Upper New Cross, London; or you may apply to Mr. Yardley, Market Hall, Birmingham.

DIVIDING STOCK BEES—DRIVING (*H. Alsop*).—We do not think you can safely make two hives out of No. 1 this autumn by dividing it as you propose. The super is too shallow to make a hive of, and the wood rim which you put to the lower part of the main hive could not be taken away without rendering the comb in it useless, as it would have to be cut away, and would fall in. Much better remove the super and keep it for another year, if there is too little honey in it to tempt you to plunder it. So also let the hive remain with the rim on; it will make a splendid stock for another year. Do not plunder No. 2, you will gain but little from it; keep it for another year.

As to No. 3, why not drive the bees into an empty hive, then catch the queen, and add them to one of the swarms? Do it towards sunset, when the bees are mostly at home, and let them march straight up into the swarm's hive, first dashing them out of the empty hive on the ground. You must put the swarm near it.

COVERING FOR A HIVE (*L. M. H.*).—Cover your hive with a large Duchess slate, putting a couple of bricks at top. You can make it incline forwards or backwards to carry off drip, by resting one end of it on a bit of wood. We fear your bees are in a bad way if you can see no honey at the windows. If this continues you must feed them without loss of time. We fear the honey season has been bad with you as with others.

YELLOW-BANDED BEES—DRONES (*W. G.*).—No. 1 of the specimens sent is undoubtedly a hybrid, the offspring of a black queen and a Ligurian drone. Your young queen must have met with a drone of the latter variety, although you say that no Liguirians are kept in your vicinity. The other bees sent are rather doubtful, the colour of the rings having probably become less distinctly marked since death. We must compliment you on the admirable method adopted by you in mounting and packing the specimens, which arrived in a condition very different from the smashed messes we are often asked to give our opinion upon. We do not think there is much advantage in the cross with a black queen and Ligurian drone, though there undoubtedly is with respect to the opposite cross. Drones are often bred in a swarm of the current year. Drone egg-laying is usually, in such circumstances, a precursor of a maiden swarm being thrown off. It is not usual for drones to make their first appearance so late in the season.

REMARKS.

- 13th.—Rain early, fine by 8 A.M., and beautifully so the remainder of the day and the night.
- 14th.—Very fine day throughout.
- 15th.—Wet early, but fine before noon, continuing so with a starlight night.
- 16th.—Dull early, fine forenoon, and till 6 P.M., then very dark and stormlike, with a few large drops of rain, but fine afterwards.
- 17th.—Fine, dry, bright, cool day.
- 18th.—Rather dull morning, a little sun before noon, rain soon after, and continuing more or less all day and night.
- 19th.—Slight rain early, and again at 1 P.M., rest of the day fine. Temperature very similar to previous weeks, but slightly declining. Rapid fall of barometer between 17th and 19th.—G. J. SYMONS.

COVENT GARDEN MARKET.—August 20.

RETAIL trade falling off. Supplies well kept up, both homegrown and continental.

From observations taken near London during forty-three years, the average day temperature of the week is 71.9; and its night temperature 47.9°. The greatest heat was 85°, on the 1st, 1843; and the lowest cold 32°, on the 2th, 1870. The greatest fall of rain was 1.50 inch.

BELGIAN HORTICULTURE.—No. 5.

M. VERSCHAFFELT'S, GHEENT.

IT is nearly a year since I spent three enjoyable hours in this renowned horticultural establishment, but intervening circumstances have prevented my sending a notice of a place well worthy of note in current garden literature. I remember noticing "Verschaffeltii" ticked on a plant label when I was little or no taller than my father's spade, and screwing my jaws into all sorts of forms to get it into my mouth. As to what it meant even the "under gardener" could not divine, and I had come to regard him as about the cleverest man alive, being fully converted by him into the belief that he knew a great deal more than the "gaffer"—very presumptuous evidence, however, offered only by presumptuous know-alls, and only fitted for children's ears.

Verschaffelt is an old and universally-known name, and is associated with many horticultural triumphs. The representative of it, M. Jean Verschaffelt, is now in the sere and yellow leaf, and his hair is silvered by the lapse of years. He does little more than enjoy himself by little cultural fancies, the practical management of the establishment being relegated to his nephew, M. Jean Nuytens. To any English gardener making a pilgrimage to the Belgian plant emporiums, and especially if he knows little beyond his mother tongue, I say, Do not omit a visit to this not extensive but interesting place, and he will find in M. Nuytens a gentleman who is certain to give him a cordial welcome, and converse in his mother tongue as well as he. I know what it is to hear a houseful of children all crying together, and a bothyful of aspiring Paganinnis learning to fiddle, but I never remember experiencing such a surfeit of sound as the daily din of French, Dutch, and Flemish which violated my restricted sense of hearing and understanding. I could get away from the children and fiddling, but a stranger in a strange country cannot get away from the babel of tongues which surrounds him, and to fall in with such perfect anglicised Belgians as MM. Nuytens and Van Houtte, jun., is in itself a "find" of the first order, and at once compels an appreciation of the English language in a way not understood before. M. Verschaffelt's is in the Faubourg de Bruxelles, and within ten minutes' walk of Van Houtte's great place, so that both may be seen under one visit, and the heads of each will willingly direct to the other.

The Verschaffelt Nursery is about the only one I visited which shows any sort of effect or symmetry in the matter of laying or planning-out. Its limited size, in comparison with some others, brings a great portion of it in the scope of vision at once; but we cannot see at anything like a glance the multitudes of good things—old, new, and rare—with which the establishment teems. The nursery may be said to be a parallelogram, with an irregular offshoot to the left, and divided from the garden proper by a public road. A broad walk runs down the centre

of the grounds, and at the time I saw it formed the site of an ornamental avenue of standard Bays, in front of which were lines of specimen Agaves, Yuccas, Buonaparteanas, &c. The Bays were splendid examples in their way: they were the very perfection of health, and as round as an orange. Many were sold at prices varying from twenty to fifty guineas per pair. The sides of the other walks were lined by fine plants, in various stages, of Araucarias, planted in baskets for safe removal, and in luxuriant health and free growth. The plant houses are grouped together near the packing-sheds and dwelling-house. They are long plain structures, devoid of ornament, but admirably adapted for their purpose, as is evidenced by the remarkably healthy condition of the occupants. Ferns, Palms, Orchids, and the whole paraphernalia of plants seem to grow like weeds, and are as clean as if every leaf had been sponged the day previous. Importations of plants are continually arriving; a lot of new Cycads and monstrous trunks of Dicksonias were just being potted. A great proportion of these must die; indeed, how they live is a wonder, but that they do live the many giant stems with green spreading crowns plainly attest. But the dead trunks, I observed, were turned to account by the tops being scooped out, and having Ferns and other things planted in them.

This place is rich in tree Ferns, the match pairs of Alsophilas and Dicksonias being both magnificent and numerous, and the demand, somewhere, is equal to the supply. Orchids are well represented in number and variety; they are not grown large, but are mainly confined to handy portable specimens. The curious forms of the vegetable world have also in this place numerous representatives, amongst which are noticeable Testudinaria elephantipes and a fine batch of the Old Man plant, Pilocereus senilis, in striking resemblance to the hoary head of a hale octogenarian. Contiguous is a lot, only a degree less singular, of Pilocereus Hoppenstedtii in strange garb and spiny.

There are Palms, too—yes, Palms by the thousand, or, as I think "D., Deal," once put it, "Palms for the million." There is only one question more puzzling than the impromptu one of Whence come they? and that is, Whither go they? Yet they are ever moving onwards in their decorative course from tiny seedlings to splendid spreading specimens in all the best old and all the rare new varieties. Well may Linnæus attempt to obscure the rest of the order of monocotyledons, to which they belong, by styling them "princes of the vegetable kingdom." Few things are more imposing than choice and well-managed collections of Palms. They are plants which one may look and look again at, and ever to admire. They have a history, too, and a use which cannot be ignored. How graphically Melville, in his "South Sea Adventures," describes the uses of the Cocoa-nut Palm, Cocos nucifera. The passage is worth reproducing here. He says, "The blessings this Palm confers are incalculable. Year after year the islander reposes beneath its shade, both eating and drinking of its fruit: he thatches his hut with its boughs, and weaves them into baskets to

carry his food; he cools himself with a fan plaited from the young leaflets, and shields his head from the sun by a bonnet of its leaves. Sometimes he clothes himself with the cloth-like substance which wraps round the base of the stalks. The nuts, thinned and polished, furnish him with a beautiful goblet; the dry husks kindle his fires; the fibres are twisted into fish lines and cords for his canoes. He heals his wounds with a balsam compounded from the juice of the nut, and with the oil extracted from it embalms the bodies of the dead. Sawed into posts, the trunks uphold his dwelling, and converted into charcoal it cooks his food. He impels his canoe through the water with a paddle made from its wood, and goes to battle with clubs and spears of the same hard material." After this, feeling my incapacity of description, I will say no more about Palms at present.

Besides the above, M. Verschaffelt's establishment contains a fine collection of stove plants of every type. Marantas and Dracenas are numerous and fine, a lot of specimens of *D. reginae* in high colour standing out effectively. They are strong, too, in the Gesneriaceae; *Eucodonia*, *Nagelias*, &c., being provided in great variety, while some fine types of new flowering *Begonias* made their presence felt; but of these, perhaps the finest collection in the world is located at Van Houtte's, to be noticed hereafter.

M. Verschaffelt had also an excellent and extensive lot of Camellias and Azaleas; all the best plants of the former were purchased in my presence by one of our great English nurserymen. Many fine sorts of Azaleas had their origin here, and amongst the rest the beautiful and free *Souvenir du Prince Albert*. Perhaps, however, I may be prejudiced in favour of this variety, but I have a reason, and when I tell it Messrs. Verschaffelt and Van Houtte will both hold me excusable, whether anyone else does or not. What appeared also distinct speciality of M. Nuyten's were *Yuccas* and *Agaves*. The latter were especially fine. What a fine and distinct type of plants we have here. There is something intrinsically good about them, and their attractions do not wear out in a season. They are being increased as fast as possible with a confidence that the future will recognise their merits. A more free use of these stately yet graceful and ornamental plants would add a pleasing and diversified feature to many gardens where they are not; but when beauty of form and substance become as fully appreciated as beauty of mere colour, then will such things be sought after and popularised as they deserve to be. Having just glanced at the outline features of this compact and interesting place, I will add no more beyond a desire to see it and the able and affable manager M. Nuyten's once again on some—it may be long—future day.—J. WRIGHT.

A YORKSHIRE FLOWER SHOW.

We are in the midst of a perfect shower of horticultural exhibitions in the West Riding. Nearly every day for the last fortnight there has been an exhibition of flowers and fruits; and villages, which from all appearances you would consider most unsuitable for affairs of this kind, astonish you by their energy and the excellence of their shows. Such an exhibition has recently been held at Elland, a large manufacturing village in the heart of the West Riding, and it occurred to me that a few notes respecting it might be acceptable to you. Staying here as I am for some weeks, I thought I would try how *Roses* would travel in one of Chapman's cases, and so I entered for the *Rose* prize; but although a friend saw my *Roses* safely delivered to the Great Northern Railway the day before the show, they have not yet arrived! So I went partly as a visitor and partly as an assistant to my brother, who staged a dozen remarkably fine blooms—*i.e.*, fine considering the time of year and the smoke-laden air which his trees have to breathe.

This part of the country is the very antipodes to the west of England. The rich people here are the labouring classes, the poor ones as a rule the masters. The colliers round here can earn £1 a-week, and the factory hands 30s. to £2. They live on the fat of the land, and do not hesitate to buy the most expensive luxuries. Early in the year a collier ordered of one fishmonger 80 lbs. of salmon for a small supper which he and his friends were going to have; and as another instance of their wealth and extravagance I can relate the following true anecdote. At a large fruiterer's shop in Bradford early in the season a gentleman inquired the price of a Fine Apple. "Thirty shillings," was the answer. "Oh, that is too much for me; my purse cannot stand that." A collier was looking in at the window, and when the gentleman withdrew he entered and

asked, "What didst thee say t' price of that ere were?" "Thirty shillings," said the shopman. "Here, lap it up, then, lad; it will do for our Sal. Here's t' brass." I expected great things, therefore, from a population like this, and I was not disappointed. The Show was excellent, the arrangements very good, and the attendance enormous.

This little Society has a subscription list of £110, and at the last year's show £113 was received at the gates, the greater portion of which sum was derived from *6d.* entrances. I wonder what the managers of our west-of-England shows will say to this. Elland had a balance this year, after five exhibitions, of £150; Cleckheaton, another village near here, £650. Indeed, wherever a flower show is held the receipts are enormous; and although this Society gives wretchedly poor prizes, yet the entries are most numerous, and the Show of August 19th would compare favourably with any but the largest exhibitions held in the south. Think of the band of the Royal Horse Guards (Blue) being engaged at an expense of nearly £80 to perform at an out-of-the-way place like Elland, besides two small country bands which played when the Guards were silent.

As to the Show itself: As I have said, it was very good, and, considering our climate, remarkably so. There were three entries for ten stove and greenhouse plants; and some magnificent specimens of *Allamanda Hendersoni*, *Ixora*, *Vinca alba*, *Vinca rosea*, &c., were staged by Messrs. W. Pontey, of Huddersfield. The *Liliums* also were magnificent. I saw one pot plant of *Lilium lancifolium* roseum with forty blooms on. *Lilium aratum*, too, was very finely shown; and *Caladiums*, *Lycopodiums*, *Campanulas*, and exotic Ferns were really very fine. The crowd was enormous—I should say at least eight thousand people visited the Show; and although they were a little rough they were always good-tempered, and were the most critical people on the subject of flowers and music I have ever met.

There was an immense competition in the cottagers' class for vegetables. Some former inhabitants of Elland who had taken up their abode in America sent over a silver cup to be given for the best collection of vegetables, and, as you may imagine, most cottagers had a try for it. The Committee had to take the greatest care to prevent unfair practices. They saw the vegetables dug up and put in baskets, which were then sealed, and any basket which was open on the morning of the Show was disallowed; and, indeed, this precaution is very necessary, for we Yorkshiremen (I am one), are rather too sharp sometimes. The cottagers think nothing of buying, or borrowing, or begging—I won't say stealing—blooms and vegetables. A man came to my brother and calmly said, "William — wants to know if you will give him some *Roses* to show at Elland." "What number of trees has he to show from? has he many?" I asked. "Nay," said the man, "he's nobbut one." And yet this fellow was calmly going to exhibit twelve and six blooms! It is almost impossible to prevent this sort of thing, but if it go on very much longer it will be a question whether it would not be better to give up horticultural shows rather than let them become a mere market place for all kinds of cheating and larceny. Mr. William Paul has most nobly exposed this system before, and all persons interested in horticulture will feel that in some way or other it must be put an end to.

There are only two things which, in my opinion, this and other societies in this neighbourhood should change. They should give better prizes and have better judges. Seven pounds for ten stove and greenhouse plants (the best prize given), is not much for a society so prosperous as this one to give, while 10s. for a collection of twelve *Roses* is simply ridiculous. As to the judging yesterday, the least said about it the better. I never saw such judging. I inquired who the judges were, and found them to be local nobodies, gardeners to gentlemen in the neighbourhood. I do not think it can be too strongly urged on committees that liberality in procuring first-class judges is as important for the interests of the show as procuring a first-class military band. I think I never saw a greater miscarriage of justice than in the ten stove and greenhouse plants and in the *Roses*. In the west of England the first thing we look to is to have good judges. Mr. Charles Turner, "*D., Deal*," Mr. Peach, and other great florists are always secured, and the exhibitors know that their flowers will be judged on their merits by persons in whose judgment they have the greatest confidence, and I think it will be well if the north take a lesson from the west in this respect. But with these two exceptions no fault can be found with the manager of the

Elland Flower Show, which was one of the most successful exhibitions I have ever seen.—JOHN B. M. CAMM, *Brighouse*.

FLOWERS FOR OUR BORDERS.—No. 15.

OXALIS ELEGANS.—ELEGANT WOOD-SORREL.

In common with most of its congeners, it is produced from a bulb of small dimensions, and appears likely to prove nearly, if not quite, hardy. The leaflets are bluntly triangular, generally of a pale green beneath, but, in some plants, of a bright reddish purple. Judging from our own specimen, we should infer that both varieties of foliage may be found on the same plant. The leaves are less numerous than in the *O. cernua* and some others; but in the case of full-sized bulbs, are much larger than in many of the species. The flower scape is about twice the size of the petiole, supporting a truss of from six to ten blossoms of a purple colour, the eye of the flower being of a very intense shade.

The sepals, or divisions of the calyx, are remarkable for four minute linear orange-coloured glands at their tips, which, although too small to be readily detected by the unassisted

Oxalis elegans.

eye, are easily perceptible under a microscope of low power, such as the Stanhope or Coltrington lens. These glands form an excellent mark of distinction. As in all the species, the petals are twisted in the bud, and form, when expanded, a flat-limbed corolla. It is a native of the Andes of Peru.

In the case of many species of this genus the new tubers annually formed require to be dug up after flowering, as they are produced at such a distance from the surface that, unless this precaution is adopted, they will eventually be lost. In the case of *O. Bowiei* and other autumn-flowering nearly hardy species, it is advisable to defer the removal of the tubers until spring, as in severe winters they would be safer at a depth of some inches; and from the late period at which the blossoms are produced, the young tubers would suffer from being disturbed in their immature state. As they do not commence their growth until the following summer, the month of April will be sufficiently early to replant them.

The bulbs of the *Oxalis elegans* do not penetrate the soil so deeply as some of the other species; but they should, notwithstanding, be replanted every autumn, after the decay of the leaves. The soil best suited to this and most of the *Oxalises*,

is a light sandy loam, with an admixture of peat or leaf mould. A dry sunny situation should be chosen, for the blossoms expand only under sunshine.

Oxalis elegans is a very free flowerer, even the small bulbs will generally produce several umbels. The trusses will need the support of a small rod to prevent them from being dashed to the ground by heavy rains; and for this purpose nothing is better than the top of a slender unpeeled osier. These supports are commonly employed by professional florists, but they are not so generally in use among amateurs as they deserve to be. Their pale bark renders them very inconspicuous, and their freedom from knots or roughness, and tapering form, makes them, in our opinion, far more desirable than the brittle hazel rods or painted sticks ordinarily used for these purposes.

The hardness of the present species has already been adverted to. It will be prudent, however, to afford the roots some protection in very severe weather; but the covering should not be suffered to remain too long, or the bulbs would be forced into premature growth.

All the *Oxalises* may be cultivated in pots; and when thus treated, they can easily be preserved through the winter in a dormant state. Considering the great interest attaching to this pretty genus, and the showy character of their blossoms, we are really surprised that they are not more frequently met with. A bed of mixed species, planted in clumps of eight or ten bulbs each, forms in sunny weather one of the most attractive objects imaginable. All the half-hardy species which flower in summer and autumn may be thus grown, and their tubers may be dug up after the leaves are withered, and preserved in dry sand. Among the most desirable species, whether for the open borders or pots, are *arborea*, yellow; *spectabilis*, pink; *violacea*, violet; *caprina*, flesh; *crenata*, yellow; *cuprea*, copper-coloured; *lobata*, yellow; *hisiopetala*, pink; *geniculata*, yellow; and *variabilis*, with its varieties *grandiflora* and *Simsii*, with white flowers.—(*Thompson's English Flower Garden, Revised by the Author.*)

POTATO DISEASE DURING WINTER.

SOME of the points suggested by Mr. Bréchant's communication on this subject were illustrated by experiences of my own, also in the island of Guernsey, during last winter; and although these have been already published in detail in the *Gardeners' Chronicle and Agricultural Gazette* of 22nd March, yet as many horticulturists may not have the means of referring to them there, a brief abstract of the results may possibly be of service in the discussion now proceeding in your columns.

On August 19th, September 7th, and September 20th, Rivers's Ashleaf and Mona's Pride were planted out of doors in a sound dry loam, moderately manured with cow manure only. Disease showed itself on the leaves and stems of all at successive periods from 1st of November to 15th of December, when the tubers were about the size of walnuts. The growth was entirely arrested, but the disease seemed not seriously to attack the young tubers—in fact these, and even the old set, in the case of the first-planted lot, showed a tendency to throw up new stems after the first growth had been killed to the ground. Over a portion of the last-planted lot glass lights were placed in the beginning of November; this delayed the appearances of the disease, but it ultimately appeared and pursued its regular course.

A further lot of the same and other kinds were planted in an orchard house of about one-eighth of an acre in extent towards the end of October. Disease appeared on these about the end of December, affecting first some that were under a drip off the glass, but ultimately spreading to the whole. No water was given artificially during the period of growth. The crop proved extremely scanty, but the few tubers produced were of fair size, and hardly affected by disease. The weather during the whole winter was very dull and damp, but mild till the end of January, afterwards cold, though not frosty.

The conclusions I drew were that the disease is not caused solely either by the season of the year, the wetness of the soil, heat or electricity (though no doubt all or any of these influences may enhance the liability or augment the virulence of the disease), but that it originates in ill-elaborated sap forming a favourable nidus to the well-known fungus. This imperfect elaboration of the juices occurs chiefly, of course, in the more tender varieties, and in summer may arise from too much grossness or luxuriance, in winter from absence of sunshine. I would recommend the experiment of passing a heavy

roller over any stems that at this period of the year appear too succulent, before the disease shows itself upon them, having observed some favourable indications from a partial experiment of this nature.—B. K., *Guernsey*.

BROWN'S WONDER STRAWBERRY.

I ENTIRELY agree with Mr. Powell's opinion of this variety; it was sown here—in fact, a weed compared with many of our fine established varieties. I had grown a stock of it, but destroyed it instead of inserting it in our list.

While writing about Strawberries, how is it we never meet with Dr. Roden's gems, so temptingly described in your last number? They are never met with in good gardens, on the exhibition table, or in any catalogue.—CHARLES TURNER.

BLUE PETER AND LITTLE GEM PEAS.

DR. RODEN, in your issue on the 14th inst., has described Blue Peter as superior to Little Gem; here it was very inferior to it. My opinion is, that Little Gem will remain a favourite long after Blue Peter is forgotten. Emperor of the Marrows is also highly spoken of; I hope, however, this will not induce any of your readers to grow it.—THE INTRODUCER OF LITTLE GEM.

POTATOES AS THEY ARE.

WOODSTOCK, OXFORDSHIRE.—After thirty-seven years of trials, and of crosses and gropings in the dark, I may say for a good third part of the first series, it really appears to me now that I have arrived at the climax. For both garden and field cultivation I have singled-out from my newest 316 seedlings, which I informed you of at the beginning of the season, about one hundred varieties for future observation and "weeding-out," and from which I hope in about another three years to hand down to posterity something still better than is known at present of my productions excepting by myself. It should take seven years to properly test a new Potato and get it ready to "send out;" so I suppose, for the reason given at the commencement of this paper, I must be cautious how I speak of a future seven years. If I be spared to enter into future crosses, I shall leave no mystery about where and how I leave off, and there will be left others better than myself to carry on the enterprise—yes, enterprise is the word—for experimentalising for the further improvement of the noble tuber will be found no joke, and I speak feelingly.

Well, since I was set to pick up a certain quantity of the old Early Shaws in my uncle's garden at Sicklesmere, before I was taken by my father to witness my first play at the theatre, Bury St. Edmunds, I have never seen better crops of Potatoes than I do hereabouts this year, and they are generally free from disease. I have also had an opportunity to a wide extent in this and other counties of inspecting the Potato and other crops, and excepting some breadths I lately saw in full blossom in Middlesex, which upon inquiry I found to be "foreigners," I should say our late English sorts will bear out their destiny; notwithstanding they are spotted more or less in the leaves, the haulms remain green and upright—a pretty good criterion to go by as regards freedom from disease in the tubers. Early and second early sorts are mostly already secured in good condition.

I have, nevertheless, seen and heard of a few diseased tubers making their appearance amongst the later sorts, notably with my own, amongst Yorkshire Hero and the old Cobbler's Lapstone, the only two "strangers" which I grew this year for comparison besides my graft hybrid Yorkshire Hero in Onwards, for carrying out the purpose of testing what difference exists between the latter and the former, which I find to be this: The hybrid is 6 inches shorter in the haulm, and ripens fully three weeks before Yorkshire Hero. When taken-up last week no person viewing the sorts as they lay upon the ground in their bulk side by side—let them be never such novices in Potato judgment, could fail to perceive a general refinement in the tubers of the hybrid as compared to those of Yorkshire Hero, and I may include also those of the old Lapstone, which, by-the-by, with Yorkshire Hero, were in their growth of haulm throughout, and in appearance of tubers, as "like as two peas" of the same sort.

There has lately sprung up a contention as to who was the raiser of Yorkshire Hero. The Rev. W. F. Radclyffe sent me the Yorkshire Hero, some years ago, as being a graft hybrid of Mr. Thomas Almond's. I very much doubted at the time if it was possible to graft one Potato into another kind and achieve a change in the sort; but the evidence I received in writing was so strongly in favour, that I determined to try for myself; and time and many trials convince me it can be done after a manner of dwarfing and refining, both in top and tuber, a strong-growing variety when it is grafted into a kind of medium growth, and that in nine cases out of ten it will utterly spoil

the grafter. I find this subject coming on the *tapis* again in another phase, but it is scarcely worth while now for me to enter into the subject in these pages, seeing that I have done so very often, without, however, being able to convince the sceptics. It may prove useful and interesting just now if you will reprint the following:—

"Bramham, near Tadcaster, May 22nd, 1866.

"These Kidney Potatoes were propagated by Major Hague, but they were raised by his son Joseph, the particulars of which are as follows:—

"I, Joseph Hague, in the year 1827, then residing at Thorne, near Leeds, planted two pecks of Potatoes, which I had sent me from Clap Gate, near Harewood. Those Potatoes produced an extraordinary quantity of fine berries, which induced me to try to raise seedlings from them. In that I succeeded, and selecting the two best from among the quantity, I again planted the seedling tubers, but subsequently removed to Bramham, where I now reside. Having no garden connected with the house I then occupied, I took my seedlings over to Bardsey, and they were planted in my father's garden; and as he was the first to propagate them, the general impression was, and is now, and is with many people to this day, that he raised them himself, but he never at any period of his life attempted to raise seedling Potatoes. I have five brothers who can all testify to the accuracy of the above statement. Mr. Fuller, florist, &c., Headingley, near Leeds, but at the time gardener to G. Lane Fox, Esq., of Bramham Park, gave the Lapstone Kidney its name.—JOSEPH HAGUE."

There are a great many Lapstone Kidneys now under as many aliases, and I had at least twenty varieties of them on trial in a field near here a few years ago, and some wags removed my numbered pegs, and for the life of me, as I had not numbered the rows in my book, I could not tell which was which of the majority of them, and so my comparative experiment came abruptly to an end. Fortunately I had presented the old Lapstone breed to Mr. Radclyffe some years ago, and this circumstance enabled me, through his kindness, to get my old variety again this spring.

Well, neighbours call in to see me with bulging pockets, to become gradually emptied as they formally and lovingly distribute along the ground fine samples of Mona's Pride, &c.—a decoy for envy. Only a wine merchant, as he hands out a sample of his choicest brand, could assume a greater air of superiority. I instinctively turn to my ridges, but, no, the proper amenities would not allow me to discover finer tubers than those of my friends, and I exclaim, "Astonishing! Why, they are equal to take a prize anywhere," and, indeed, I was not far from the truth. Again, a connoisseur of the Potato walks proudly in, holding out a plate nicely covered over with a clean cloth. "Apricots, I hope!" No, a plate of my Onwards seedling Potato, which he swears by. But his is a small town garden, which just suits the Onwards, as the ground has been enriched within the last few years, sufficiently even to grow exotic plants, merely by the application of his house sewage and the contents of a dry-earth closet, which he also swears by. I will only say I am of the same opinion, as this garden has had no other manure for the last twenty-five years, except leaves and other refuse of the premises, than the contents of the rectory-house sewage tanks and the dry-earth closets, the first, I believe, that England possessed, and no household could have been healthier than this for the last quarter of a century, notwithstanding the theory that have lately gone abroad condemnatory of such manure. I can speak, and have spoken pretty often in this and other periodicals, decidedly in favour of it, and if I were a person inclined to feel ever so little conceited, I would advise Her Majesty's Sanitary Commissioners to send down a special inspector to interview these premises, as I consider our sanitary arrangements in connection with our water tanks and supply to have worked out all the aims that the generality of people seem to be wishing for. At any rate, if Mr. Smee's letters were to receive heedless credence it would be a national misfortune. From long experience with house sewage and the contents of dry-earth closets, I can confidently say they afford the best and the most innocuous manures that can be applied to the soil; but the land should be allowed time to analyse, and the plants to digest them or any other manures, before the produce is eaten by either man or beast. A three-course system is what I adopt as nearly as I can for garden ground, but it would be more completely adapted to farmwork. Say, deluge a third, field by field alternately, under green crops, such as Turnips or Rye-grass, then take Potatoes or pulse crops; and for a third course take grain with a dressing of lime, or some such practice, which will prevent the land being continually under sewage which it cannot profitably make away with.—ROBERT FENN, *Rectory, Woodstock*.

TORTWORTH, GLOUCESTERSHIRE.—Up to the present time no diseased tubers have been observed among our early crops, which are excellent and clean-skinned. As a rule, garden crops are the first to suffer, particularly on close moist soil, and the evil is no doubt accelerated by too high feeding. Curative remedies without number have been offered us, but they have to a great extent proved of little value. Nothing is so certain as the selection of early varieties and spring planting, so as to insure maturation by the end of July or beginning of August. The disease has made its appearance among our field crops, but as yet to a limited extent; and should the present favourable weather continue, I believe this will be a more prosperous year

for the Potato than many previous seasons.—ALEXANDER CRAMP, *Tortworth*.

OXFORD FITZPAINE, DORSET.—The Potatoes here are very sound—hardly a diseased tuber. I hear the coarse-growing, deep-eyed, late-ripening Potatoes are spearing-out. I dug-up twelve plants of Prince of Wales a few days ago; the new tubers were like porcupines and not half ripe. I shall finish digging all Potatoes to-day (August 23rd, or on Monday, the 25th). I have heard no complaints of unsoundness from my neighbours.—W. F. RADCLIFFE, *Oxford Fitzpaine, Shillington*.

P.S.—All my Potatoes are up to-day (August 25th), and in a quarter of an acre there are not enough diseased ones to fill a small handkerchief.

SANDRINGHAM, NORFOLK.—I am glad to say as yet our Potatoes are but slightly affected. I found a Danish Potato here that took the disease very much, all our English varieties only partially.—CHARLES PENNY, *The Gardens, Sandringham, King's Lynn*.

KNUTSFORD, CHESHIRE.—On Saturday last I lifted a quantity of Paterson's Victoria, a fine splendid crop, but much affected. The various species of Kidney, Old and Royal Ashleaf, Gloucestershire, and Mona's Pride similarly attacked. From the tubers failing after being lifted, I thought a washing might arrest the progress of the disease, consequently I have taken the trouble for these last two years to wash those sorts which were of most value, then spreading them on a dry boarded floor. This process is not labour lost; when the tubers are thoroughly dry they may remain, if convenient, or be removed to the pit.—JOSEPH BURGESS.

WYCOMBE, BUCKS.—At the present time the Potato crop in this vicinity, both on the hills and in the valleys, is most satisfactory. Many of the earliest varieties are already lifted, and with the best results both as regards quantity and quality, and with scarcely any disease; in fact, none worthy of mention. The haulm of the later kinds, which are not yet ripe, show in some places indications of disease, but the tubers are not yet affected.—GEO. THOS. MILES, *Wycombe Abbey Gardens*.

CHISWICK, MIDDLESEX.—The present season has been exceptionally favourable for the growth of the Potato. On the 20th of May the tops of a great portion of the earlier-planted varieties were much injured by frost, and some bore traces of this all through the season. The greater portion, however, soon recovered and grew with great strength and vigour. The first appearance of the disease I noticed July 20th, on Early Goodrich, Red Emperor, and some Dutch sorts. A few days later the Lapstones were attacked, and the disease gradually spread over most of the varieties. Although the tops have been so far attacked that in some cases all the foliage has been destroyed, there are but few of the tubers affected. The season has been on the whole dry, the Potato crop is large, and the quality excellent.—A. F. BARRON.

LEDBURY, HEREFORDSHIRE.—The Potato crop in this district is the heaviest that has been known for some years, and the tubers are unusually fine and clean. Disease—as is generally the case when the atmosphere is heavily charged with electricity, as it was in June and July—made its appearance earlier than usual, affecting some kinds more than others. Lapstone Kidney, one of the best Potatoes in cultivation, has suffered most; and although slightly touched, Paterson's Victoria is least affected. Of early kinds, Veitch's Early Ashleaf and Stratton's Seedling have yielded fine crops free from disease. The red American kinds are extensively grown in this neighbourhood, and are gaining in favour; the season having suited them, they cook drier than in former years.—W. COLEMAN, *Eastnor Castle, Ledbury*.

BOWOOD, WILTSHIRE.—I am pleased to be able to give a favourable account of the Potato crops in this neighbourhood, which are very good—much better than I have known them for several years past. The disease, which has made its appearance in the haulm since the first week of the present month, has not shown itself very much in the tuber up to the present time. I find that where the crops are surrounded by trees, which prevents their being fully exposed to the sun and air, the disease has affected them most, the haulm having almost disappeared. In such places a few diseased Potatoes are to be found.—WILLIAM SCAMMELL, *Bowood*.

CHILWELL, NOTTINGHAMSHIRE.—I think the Potato crop is very good here. The first and second earlies have turned out well, and almost free from disease. I hear from everyone their late sorts are a more promising crop than usual, and there is, I think, little amiss with them at present. We have a great deal of wet and many thunderstorms just now, so people are beginning to fear for their late Potatoes.—J. R. PEARSON, *Chilwell*.

EAST LOTHIAN.—The Potato crop in the East Lothian up to this date may be said to be free from disease. I have heard of tubers having been found in several places which had the disease, but it has nowhere appeared on the foliage that I am aware of—certainly not in the higher districts of the county. The last week's weather, however, has been in every way likely to induce dis-

ease—continuous rains and foggy, and the wind in the east and south-east; so that I should not be surprised to see it any day make its appearance on the stems and leaves. In all parts of the county the crop will be a large one. A large breadth has been planted, and it will be a sad loss should the disease come now when the crops are all looking so well.—ALEX. SHEARER, *Foster Gardens, Haddington*.

HINDLEF HALL, WORCESTERSHIRE.—Potatoes grown in the gardens here were harvested three weeks ago; a fine crop, first-rate in quality, about thirty tubers diseased. Early varieties in fields and gardens in this neighbourhood are good in every way: very little disease. Late kinds are more promising than they have been for many years past, and a wonderful contrast from last season. My Potatoes for the last eighteen years have virtually been free from disease.—A. MOFFAT.

BUNTED, SUSSEX.—The yield of all kinds of Potatoes is excellent, and the crop is being housed in capital condition. Traces of disease have been found in the late sorts, but it prevails generally in a very mild form, the only bad exception being Bresee's Prolific, which has quite half its fine tubers affected. Symptoms of sprouting, or that second growth which leads to super-tuberating, were discovered early in the month. The kinds affected were, however, so forward that they were lifted before any serious harm was done. On the 13th inst. and following three days a large breadth of Paterson's Victoria and Flukes were lifted and taken to the storehouse. These crops were very fine; they are now stored thinly under a slight covering of mats and straw, and being housed during the prevalence of fine sunny weather, they are as dry and sound as could be wished. The quality of Victoria is as usual most excellent. It may be interesting to note, that these late-keeping Potatoes were sufficiently ripe for lifting within twenty weeks from the time of planting.—EDWARD LUCKYRST, *Old Lands, Buncted*.

APPLETON-LE-STREET, YORKSHIRE.—I have heard of no disease amongst the Potatoes in this neighbourhood this year, nor have I seen a single diseased Potato. The crop promises to be a heavy one. I have tried several sorts of kidneys—Ashleaf, Royal Ashleaf, Gloucestershire Kidney, Ashtop Fluke, &c., and hitherto the Ashtop Fluke has been far superior to any other—in fact, I do not remember to have ever eaten a better Potato. A very fair crop, not very heavy, but good; the tubers very clean in their skins, and when steamed in their jackets they peel firm but mealy, without any hard ends, which both the Milky White, Gloucestershire Kidney, and Royal Ashleaf have been inclined to have. From inquiries I have made at different provincial shows, and the samples of Potatoes shown, I think we may fairly reckon upon a sound and heavy crop in this portion of the North Riding.—C. P. PEACH.

WINCHESTER, HAMPSHIRE.—As regards the Potato crops in this locality, the result of my own observation and experience is in every respect most satisfactory; in fact I have not seen a single diseased Potato this season. Owing to the fine dry weather in July and August, our own crop is safely up and housed, being spread about 1 foot to 15 inches in depth in a good dry Potato house, with the exception of a few Red-skinned Flourball, which we may possibly leave in the ground until the end of September, or even later, as a test to see how far they may become diseased, so much having been said about this variety not being liable to the disease.

Our main crop is the Dalmahoy, which ripens early. Ours were all up and housed by the last week in July, and a beautiful sample they are. Some years ago we had them all up by the 19th of July, but last year (1872) we lost nearly one-third of our crop on account of not being able from one cause and another to take them up until later, and the wet weather had also something to do with it. We plant early, and take up early, and the ground is all again cropped with Turnips, Celery, and other things. Of course we change the crops as much as we can.

Now for hearsay. In Winchester and its immediate vicinity I have not heard any complaint of disease as yet; but possibly it may occur in low damp situations, though not at present noticed by the owners. I have heard it is bad about Hursley and Romsey.—THOMAS WEAVER.

LINCOLN.—Up to the present date (August 25th) the Potato crops in Lincolnshire are sound. The time, however, is critical, and what a few days may bring forth it is impossible to anticipate. Last night, or rather early this morning, the weather has been quite of a Potato-disease type, the lightning being one complete and almost unbroken blaze, and the thunder one incessant and continued roll, while the rain has come down in torrents—nearly an inch in six hours. The storm travelled from south-east to north-west, and it is therefore in the highest degree probable that it would reach the great Potter district in the Isle of Axholme. If we have a week of dull drizzly days with evaporation and transpiration nil, and at the same time a mean day and night temperature of 65 to 70°, disease is almost certain to follow; but with brisk winds and cool nights, notwithstanding the high electric state of the atmosphere and heavy downpour, the crop would probably escape serious injury. The

risk is certainly greater by the storm coming when the ground was already moist from a still heavier rain last week— $1\frac{1}{2}$ inch in twelve hours, with much lightning. In this case, however, drying winds and sun followed immediately, and no disease was engendered. Hope lies in easterly or northerly winds continuing, as they are generally cool. When I say "no disease," I speak generally and according to ordinary acceptance, for little patches in low wet places are spoken of, but so limited as to be hardly worth mentioning.

As to the crop, the earlies are up and have been very productive and excellent in quality; and the general crop of late kinds, by their healthy vigour, give promise of an abundant yield, supposing they withstand the ordeal through which they are now passing. For years past the crop has not looked so really well. A fine March was favourable for planting, and the only check to after-growth was a touch of frost on April 26th. May was showery, inducing a sturdy growth, and June and July fine and dry for perfecting the earlies. The second week in August the late crop was in jeopardy by excessive heat and drought; but on the 18th, just at an opportune moment, before the skin was set, relief came, and the drooping stems became erect at once, and the tubers commenced swelling rapidly.

Regents are more scarce than usual by last year's devastation, and Rocks may be said to be the staple field kind. Victorias, however, are tolerably plentiful, and Red-skin Flourballs are finding their way into most farms and gardens. Besides these, owing to scarcity of seed, many tons of imported Dutch and Belgian kinds were purchased in the markets and planted. Some came up weakly, a few not at all, but the great bulk promise remarkably well, and are looked forward to with special interest. The table quality of all kinds which have ripened show to advantage under the heat and drought. American varieties are better than they have ever been before, the Early Rose being quite mealy and really good. But the best of all as a second early that has been judged here by discriminating Potato palates is undoubtedly Carter's Ashtop Fluke. It is quite first-rate, and with plenty of room is productive, but grown too closely together is a weed. Unless untoward weather overtake the crop, the Lincolnshire yield of Potatoes can hardly fail to prove itself amongst the best of past years.—J. WRIGHT.

ILFORD, ESSEX.—The Potato crop is only moderate this year, owing, principally, to the bad state of the ground and a severe frost which cut down the plants shortly after they came through. I have heard of large crops, but on investigation it is found an approximate calculation only had been made. On the farm at Loxford they are digging about one acre per day, which on the average yields about six and half tons per acre, four tons of which consist of "ware," one and half ton of "middlings," and the rest "pig chats." No disease has been seen as yet, but symptoms of it were observed for the first time yesterday; these symptoms consist of a number of white dots scattered over the Potato, and I am assured these are the certain forerunners of disease. The atmosphere is at present overcharged with electricity.—J. DOUGLAS, Loxford Hall Gardens.

BICTON, DEVONSHIRE.—Having read about the advantages of rolling Potato fields on the recurrence of disease, it may be worth notice that the experiment has been tried here with the most satisfactory results. Potato disease made its appearance with us on the 14th of July, when a most promising field of over three acres, then in full flower, was thoroughly rolled up, down, and across with a heavy one-horse roller, firming the ground and bruising Potato-stalks as much as possible. From careful examination it soon became evident that the plague was greatly checked, if not stamped out, no extension of it having been observed since the operation. Potatoes go on ripening with healthy foliage, a few lateral shoots only having grown out from their stems. The field under notice was planted about the middle of March in rows 2 feet 6 inches apart, and with medium-sized tubers 1 foot from each other.

Early varieties are now stored, and have turned out an excellent crop, with scarcely any disease amongst them; the quality is also all that could be desired. Late sorts also promise to be an abundant crop, of good size, and with no trace of disease in them at present. The exposure is open, and the manure used consisted of well-rotted leaves from Pine-pit linings, to which were added a little bone dust, coal and turf ashes, wood ashes, and soot, well mixed and sown in the drills. In a Potato plot a few yards off the field, where rolling the ground was not resorted to, Potato stalks have nearly disappeared by disease. From this statement the inference may be fairly drawn that if rolling Potatoes at the proper time—which is on the very first appearance of spot on the leaves, not days after, as that would be labour lost—if not preventive, is palliative, and I strongly recommend Potato-growers to give the practice a fair trial and publish the result.—R. BEGIE, Bicton Gardens.

GARDEN NETTING.—Permit me to bring to your notice the fact of there being another victim of garden-netting advertisers.

I ordered 45 yards of two-yard-wide netting, and had sent me a quantity of mended-up rubbish, which when stretched did not measure 3 feet. This netting was advertised as new and 2 yards wide, price 1d. a square yard. "*Experientia docet stultos*," and it will teach me to be more careful in avoiding these rogues in future.—EMSWORTH.

THE ROYAL HORTICULTURAL SOCIETY'S COMMITTEES AND ARRANGEMENTS.

An idle rumour has got about that the Council of the Royal Horticultural Society has decided to discontinue the fortnightly meetings of the Fruit and Floral Committees in 1874. We assure our readers that there is not the shadow of a foundation for such a thing. At a meeting between the Committee of Council and the Committee of exhibitors held last week, the greatest solicitude was shown on the part of the Council to preserve, and even to extend, the true horticultural character of the Society, without which it would be no Horticultural Society at all.

As I have often launched my spear at the arrangements of the Royal Horticultural Society, I hope I may be allowed to add my congratulations on the change which has come over the face of things at South Kensington. The curtailment of the number of shows must be a relief to exhibitors, who have been worried by their frequency, while it will somewhat save the credit of the Society with the general public, who, having paid half-a-crown to see an exhibition of which they have said continually, "Is this all?" feel generally disappointed. Moreover it will, we would hope, tend to reduce the expenses for bands, &c., which form so considerable an item in the Society's expenditure. Nothing could be better devised than the plan of forming a joint committee to decide upon the schedule for next year; and I feel quite confident that when the names of the gentlemen selected shall have been made known, it will inspire the horticultural public with confidence in the honest intentions of the Council to make the Society a real representative of the horticultural interests of the kingdom. We have, let us hope, seen an end of two things always injurious to any society—the spirit of exclusiveness, and the ruling by cliques. A seat on the Council will no longer be coveted as an *entrée* into society, but as a place where work is to be done for the good of horticulture; and notwithstanding the incubus of the Commissioners, which, like an old man of the mountain, hampers the Council, they will, if they act in this spirit, be so supported by the good feeling of the great body of the Fellows, that they will be enabled to steer clear of the difficulties which surround them.—D., Deal.

UTILISATION OF HEAT.

HAVING read in your paper on several occasions articles and letters upon heating power, which plainly showed me a good part of heat was lost in the present system of heating conservatories, &c., I set myself to utilise this lost heat with the following results. A small gas boiler was made as follows:—

A chamber of copper $3\frac{1}{2}$ inches square and 5 inches high, with a zigzag funnel rising from it $4\frac{1}{2}$ inches, with a hole $3\frac{1}{2}$ inches long and five-eighths of an inch wide, which was enclosed in a case of good galvanised iron, 4 inches square and $9\frac{1}{2}$ inches high. This arrangement allows only a little space between the encased chamber, with funnel and the outer case, for water to circulate in. This chamber and funnel are connected to the outer case by means of flanges. The flow-pipe is on the right-hand side, at the top of the boiler thus formed, and the return pipe underneath it at the bottom. Pieces were cut out of the sides to gain admission to the chamber; the opening thus made serves as a door. Beneath the boiler is placed a piece of perforated metal, which serves as a stand, and regulates the supply of air to the gas when burning. Surmounting the boiler is a cap, from which rises the chimney.

The latter is about 10 feet long, running obliquely and rising 1 foot in 10 feet. To this small boiler I have attached 30 feet of $1\frac{1}{2}$ -inch ordinary malleable iron pipe filled with water. The gas is applied in the chamber through a burner made partly on Bunsen's principle, and regulated by an ordinary gas-burner, allowing 3 feet to pass hourly. The heat generated

by this small amount of gas is nearly exhausted in the chamber (which absorbs the radiated heat) and the zigzag funnel, and heats the water in the 30 feet of piping to boiling in about two hours. The whole of the heat, however, is not yet exhausted, for there rises steam (which is the product of perfect combustion, and not smoke), from the burning gas through the funnel, which is of about the same temperature as the water in the boiler (212°). This passes into the chimney, and the chimney being in an oblique position does not allow the steam (which is so finely divided when it leaves the funnel that it cannot be seen, but may be felt by placing the hand over it), to pass freely into the air; while it is detained in the chimney the heat is spent upon the pipe, making it a good heat; the steam at the same time is condensed into water, and the water thus formed runs down on the inside till it reaches the bottom, where it is caught by a small tube which conveys it to the return pipe of the boiler. The water thus obtained is a never-failing supply, and is more than sufficient to maintain the waste continually going on in the boiler and pipes. When boiling point has been attained, one-third of the gas may be turned off, the remaining gas being sufficient to keep up a good heat in the 40 feet of pipes, an extent which, I believe, has not been heated by such a small power until now.

come to see and be seen, who think the band of the Guards far beyond the loveliest banks of flowers ever seen; and here, too, the real lovers of flowers, who delight in the opportunity of meeting their brethren, and of having a chat over their favourites, be they Orchids, Roses, or any of the fair denizens of Flora's kingdom. But here I am bound to say the likeness ceases. There is no muddle; there is the utmost consideration shown to all; exhibitors are regarded, not as those who are making a good thing out of the Society, but as being the main causes of its success. There may be disappointment; some have not sent who promised, yet no malediction is hurled at them but "We can do without them," the philosophical commentary on their failure. Judges are treated with the courtesy due to men who have an onerous but honourable task to fulfil; I can never call it a thankless one, for in the provinces, at least, we receive thanks in abundance. Secretaries and Committee are of one mind, and all goes smoothly "as a marriage bell." Such has been my experience this year of Leeds and York, and now of Taunton, and I dare to say, from former experience, will be of Manchester.

The Exhibition this year at Taunton was in many respects a great improvement on that of last year. Prizes of £20, £15, £5, and £3 had been offered for twelve stove and greenhouse plants, and brought together a goodly array of fine plants, the first prize being awarded to Mr. Cypher, of Cheltenham, and

A. Boiler. C. Tube to collect the water. E. Apparatus to prevent down-draught. F, F. Resters.
B. Chimney. D. Hot-water pipes. F. F. Resters. Dotted lines, another arrangement for pipes.

From the experiments I have indulged in I gather that if greater heating surface—in the above small boiler there are nearly 200 square inches—were given in boilers, more hot water could be obtained than in the present systems of heating. If properly managed, the heat which passes up the chimney can be utilised; and, moreover, in gas-boilers the steam produced by burning gas can be made use of when condensed by the process described. One other difficulty I surmounted in my experiments—I invented a small and simple apparatus to fix on the top of the chimney, which simply makes it impossible for wind to get into the chimney from above to blow out the gas, and at the same time it does not interfere with the up draught. Of this invention I do not now intend to say much, as it has just passed into the hands of a chimney-pot manufacturer, who intends to bring it out as a chimney-pot which will prevent any rain, hail, or wind getting down a chimney. This invention gave me great satisfaction, for I know many habitations will be benefited which are troubled with rain, hail, and wind being driven down the chimney.—Geo. SMITH, 9, Caroline Street, Kendal.

P.S.—Would you kindly inform me if water or steam from burnt gas has been made use of in any other heating apparatus?

TAUNTON DEANE HORTICULTURAL AND FLORICULTURAL SOCIETY.

AGAIN it has been my pleasant privilege to assist at one of those provincial shows which so fully evidence the horticultural tastes of our people, and form so pleasant a means of bringing together both gentle and simple. How one sees human nature is ever the same, whether in town or country; here, as well as in London, the same groups of anxious exhibitors and still more anxious gardeners; here to be seen, too, the man who, like the inevitable dog on the Derby-day, must ever appear on the scene, hot and angry because his pet productions have not received the award he at least thought they deserved; here the same groups who care not a doil about the flowers, but who

the second to J. B. Saunders, Esq.; in this the competition was open to all, while in the amateurs' class some excellent plants were also shown. Ferns were exhibited in admirable condition, and I have rarely seen finer masses of Lycopods than those exhibited on this occasion. When I say that Messrs. Kelway & Son exhibited Gladioli, it will be at once seen that there was something worth looking at. Mr. Dobree, an amateur, and a very successful one, exhibited some fine stands. There were also some excellent stands of Asters, both French and German, exhibited by Messrs. Kelway & Son, Dobree, and others—stands that would not be out of place at any exhibition. There was, as is usual on the occasion of provincial shows, an excellent display of vegetables and fruit. Among the former were some very beautiful Kidney Potatoes exhibited by Mr. Millar, of Sherborne, called Lady Paget, a very clean, well-shaped tuber, and which I was assured was equally good for use.

It would be needless to particularise all the excellent things exhibited, and although it may be invidious to single out of so many good things those that were not up to the mark, I must yet say a word about the table decorations. Good prizes were offered, but they only brought out one competitor, and the table was so poor and mean that the Judges were obliged to withhold the first prize, and had grave doubts whether they ought to give even a second. When I recollect that Miss Hassard has exhibited at a previous show, it cannot be from ignorance of what is correct that this table was set up, and I hope another year may bring a keener contest and a more correct taste.

The day was evidently regarded as the holiday of the year; the town was *en fête*, shops were closed, and all classes seemed to thoroughly enter into the spirit of the holiday. As in most of these cases, success is mainly owing to the exertions of a good and indefatigable secretary; and in Mr. Saunders the Society possess one who combines courtesy with zeal, and in endeavouring to gratify the wishes of all concerned, he does not forget that firmness is necessary to keep things straight.—D., Deal.

FLOWERS IN MEXICO.—One thing which strikes one pleasantly in Mexico is the wonderful abundance of flowers. All the year round crowds of Indians sit at the street corners in the

early morning making, and selling for a real, bouquets which in London or New York could not be got for a guinea. Roses, Verbenas, Heliotropes, and Carnations grow like weeds; and, besides the made-up bouquets, the Indians from the mountains bring down packs on their backs of the "Flor de San Juan" (Bouvardia), a flower like an immense white Jasmine, and for a "quartilla" (1½d.) you can buy an armful of it, which will scent a whole house for a week. Our rooms were always fragrant with the bouquets which came in every two or three days, and sometimes round the hanging baskets in the windows a lovely humming bird would hover like a living emerald, and dip his long bill into the flowers for honey.—(*Good Words*.)

A FEW NOTES ON STRAWBERRIES.

I HAVE read with interest the various communications on Strawberries, and am rather surprised not to see any mention made of two sorts of which I am in possession—namely, *Souvenir de Kieff* and *James Veitch*. The former I have grown for several years, and have found it an excellent Strawberry, an abundant cropper, of good flavour, and a good traveller, which is a great point in its favour; it also remains a long time in bearing, ripening-off the latter part of the crop nearly equal in size to the first. I was induced to grow it by seeing Dr. Hogg's commendation of it in *THE JOURNAL OF HORTICULTURE* some years ago. *James Veitch* is another Strawberry I hope to retain in my collection, as it is one of the finest-flavoured Strawberries that has come under my notice for years, and will, no doubt, become a favourite when better known. It will succeed to a certainty on light soil as well as heavy. A gentleman, whom I know to be a good judge of fruit, paid me a visit during the Strawberry season, and after tasting *Lucas*, the Amateur, Sir J. Paxton, and several others, pronounced it the best flavoured of them all. The plant is hardy and very prolific, and the fruit firm when ripe, and will bear packing and travelling well.

I am glad to see that Dr. Roden has obtained these properties in some of his new varieties, as such are most essential for market purposes. I am sorry to find *La Constante* deficient in the above good qualities, particularly in wet seasons; the fruit is then so very soft that it will not bear a touch, pack it how you may. I am in favour of Mr. Luckhurst's system of Strawberry-culture, which is the same as that which I have adopted for years, and I always found that whatever I planted after Strawberries gave a good return.—W. GRAVES, *Market Gardener*.

NOTES AT SOUTH KENSINGTON.

WEDNESDAY, August 20th, was the show of Gladioli and Hollyhocks, and these two elegant and noble autumn flowers have seldom been seen to better advantage. The Hollyhock has been long grown, and one would almost suppose that very little improvement could take place in the build of the individual flowers and the formation of the spikes, but the fact that Lord Hawke obtained six first-class certificates from the Floral Committee in one season shows the falsity of any such reasoning. Not only has he improved the flowers, but he has obtained new colours as well; his *Vanguard* and *Lilac Queen* are quite distinct.

The Gladiolus has also been vastly improved within the last six or seven years. Mr. Kelway has made a speciality of this flower, and is rapidly improving it, but there is much need still for variety in colour. We want a few more dark varieties. *Jupiter*, one of M. Souchet's new sorts sent out last year, is a move in the right direction; it is a maroon crimson, but is a very delicate sort, and the flowers are too far apart on the spike. The new ones sent out by the foreign growers this year are in no way remarkable. One variety which I exhibited at South Kensington named *Octavie* seems to be the best. *Addison* is distinct, a sort of elaret colour, and the spike is good.

There is much grumbling amongst the growers about the degeneration of their roots. Well, I fancy a good deal of it is their own fault. If you overfeed anything that has life, be it animal or plant, the result will be a disarrangement of the system. The Gladiolus is grown year after year in ground highly manured, and this is not enough—it is supplied with as much manure water as the roots will take up, and the result is death in many cases, and in others grand spikes for one year; but as far as my experience has yet gone, the same roots will not stand driving another season. As to the disease,

which has been so much written about, I do not think we can say anything about the nature of it. I have many spikes which change to yellow prematurely. I believe everybody who has grown the Gladiolus for one year will have seen it. Mr. Dombain says it is the disease, but on pulling such plants up in the collection at Loxford not a root is spotted; but as our collection is very large, we can afford to destroy all such, and thus the unhealthy roots are reduced to a minimum.

I have just looked over your announcement of the arrangements of the meetings of the Royal Horticultural Society for next year. I do think it a wise step to reduce the number of shows, but I do not at all like the first week in September for the autumn show; if the Gladiolus is to be introduced, the best blooms will be over. If it could be held one or two weeks earlier it would be better for the Gladiolus, and I fancy if the *Dahlia* and *Hollyhock* exhibitors were consulted, it would be found to answer equally well for them.

There were also exhibited at this meeting three specimens of a remarkable Cockscomb from Mr. McLachlan, of Glasgow. The dimensions were given in last week's number. I have seen very good Cockscombs exhibited at different provincial shows; I have grown and exhibited some very good ones myself, and have taken first prizes with them; but anything to equal the Glasgow specimens I have never seen. There was considerable discussion amongst the fraternity, whether it was a new variety, or whether such excellent examples were only the result of good cultivation. The Committee evidently held to the latter opinion. Mr. McLachlan says it is a cross between a variety he received from America and the old Scotch variety. He says the difference is quite perceptible when they have been staged for competition at Glasgow. I think it would be well if the Royal Horticultural Society would give a prize for Cockscombs. They are grown by several people in the neighbourhood of London. A bank of well-grown specimens would form a novel feature at the September show.—J. DOUGLAS.

TRICKS OF TRADE.

THERE are few persons who engage in the interesting pursuit of attempting to improve flowers and fruits who are not encouraged as much by the love of fame as by the hope of pecuniary reward. There are some few, indeed, who never wish to make money by their seedlings, and many who may be actuated by a mixture of motives who fail to do so. A man who raises a single seedling may raise a fine variety, but he who intends to be a successful raiser knows that number is an important element in his calculations. There is a fascination in the employment which resembles that which gamblers appear to feel, though without the injurious moral effects of their pursuit. To raise a new and good flower or fruit, not by mere chance, but as the result of careful breeding, appears almost like a creation, and I believe the raiser has a keener enjoyment than falls to the lot of the man who is only a cultivator. But this, like every other pleasure, has its drawbacks. The small number of prizes to the multitude of blanks is a serious consideration; and if he has been successful in the past, the difficulty of making further improvements often appears an increasing one. Thus to keep up the same rate of improvement we are annually tempted to greater exertions. Now, if the raiser is important to horticulture, he ought not to be robbed of half his reward—that is to say, of his fame, when he happens to be successful.

These remarks will not appear uncalled for to any person who has been a successful raiser of any fruit, flower, or vegetable. How often do we find our pets renamed, or sent out in such a way that others have the credit of their production. Raisers, like artists, are said to be a vain race, and perhaps only raisers know how vexing these things are.

I have been induced to make these remarks by a perusal of Mr. Cannell's catalogue, seventeenth edition, just received, which I think appears as unfairly compiled as any ever published. It is known to many of your readers that one of my hobbies has been the raising of bedding Geraniums, and that I have grown thousands per year to pick out a dozen, but the public is often ignorant of the fact that a favourite sort came from Chilwell. This is inevitable, because in naming a plant it is impossible to always name the raiser; but the case to which I call attention is quite another affair. The facts are these: In 1871, having been unusually successful in raising sorts that appeared worth cultivation, I sent out twenty-four varieties in 1872; and that no one might be dissatisfied in case all were not equally good, I not only charged a low sum for

them—50s. including package, but to persons in trade like Mr. Cannell sent extra plants gratis. These were the kinds so splendidly shown by Mr. Brise and Mr. Catlin lately at Kensington. Now, page 56 in Mr. Cannell's catalogue there is a list of "Mr. Pearson's new varieties of 1872," which contains eighteen kinds (one of these being a sort sent out the year before); and on referring to other parts of the list will be found the following names—Corsair, page 53; Col. Holden, Rev. C. P. Peach, Lawrence Heywood, page 54; Florence Durand, Rose Bradwardine, Mrs. F. Burnaby, Anaranth, Amy Rebsart, Mrs. R. Hole, page 55; the cream of this collection of 1872, without one single word to indicate that they were raised by me, or that they formed part of the collection of 1872 received from me!

When Mr. Cannell and others showed at Kensington my varieties for the prize offered by the Royal Horticultural Society for new bedding Geraniums, without any remark to indicate they were not their own productions, I thought it bad enough; but to advertise the cream of my collection as though he were the raiser, and put my name to what may be considered as the skimmed milk, is rather more than one is called upon, I think, to bear.

Then, again, on page 58, there is another list headed, "Highly recommended, and sent out by Mr. Pearson," without any date. Would any person doubt these were sorts just sent out by me, instead of kinds put in commerce in 1870, which is the fact? Mr. Cannell will find this sort of thing will not do; a bear robbed of her young is a savage animal, so is a raiser robbed of his honour.—J. R. PEARSON, *Chilwell*.

SPURIOUS CHERRIES.

I THINK many persons have reason to thank your correspondent, who wrote at page 63 about spurious May Duke Cherries, for drawing attention to the subject. I trust our gardeners will be alive about it, and try to preserve some of the real stock before it become extinct. I have been a victim to the present state of things for years, and could fill a folio, I think, with histories of my disappointments in May Duke especially, and I might add other Cherries also, but I will not inflict so much on you; suffice it to say that I gave up one of my best positions on a good south-east wall to a young May Duke, as I supposed, some ten years ago. This being a high situation, what with bad seasons and one thing or other, the fruit that we picked from the tree was always small, poor, and tasteless. This year it is, if possible, though abundant, worse than usual, so that I concluded it must have been a delusion of my youthful days (like Dickens's treacle tarts) that May Duke Cherries were so delicious, and I had resolved to take up the tree and dedicate its place to a Beurré Bose Pear. Your correspondent's letter has, however, opened my eyes at last. I wish he would add to our obligation to him by hinting where a really good May Duke could be obtained next planting season. My May Dukes (so called) this year might well have passed for small, poor, early Morellos.—C. H.

I saw a letter published last week, asking if it is true that a Blackberry grafted on a Dewberry (what is a Dewberry?) produces a splendid fruit, like a bunch of Grapes. I cannot credit this, can you?

[The Dewberry, *Rubus cæsius*, belongs to the same genus as the Blackberry. It is a small trailing Bramble, common in our hedges. There is no truth in the statement.—Eus.]

EXPERIMENTS IN THE CULTURE OF FIGS IN CALIFORNIA.

EXCESSIVE quantities of fruit are now put up in tin cans in this State; and you will be surprised, perhaps, as I was the other day, to hear of an orchard of Peach and Apricot trees, which bears this year its first full crop, and for one hundred acres of which the owners have received \$10,000 cash—gold, selling the fruit on the trees, without risk of ripening or trouble of picking. Yet Peaches and Apricots are not the most profitable fruits in this State, for the Cherry—the most delicious Cherries in the world grow here—is worth even more; and I suspect that the few farmers who have orchards of Plums, and carefully dry the fruit, make as much money as the Cherry-owners. There has sprung up a very lively demand for Californian dried Plums. They bring from twenty to twenty-two cents per pound at wholesale in San Francisco, and even as high as thirty cents for the best quality; and I

am told that last season a considerable quantity was shipped eastward, and sold at a handsome profit in New York. The Plum bears heavily and constantly north of Sacramento, and does not suffer from the curculio; and the dried fruit is delicious and wholesome. Some day the farmers, who are now experimenting with Figs, will, I do not doubt, produce also a marketable dried Fig. The tree flourishes in almost all parts of the State. Usually it bears two and often three crops a-year; and it grows into a noble and stately tree. So far, the preparation of dried Figs has not been successful here. In the fruit stores you see abundance of Figs, but they are generally brown or black in colour, and not tempting to the sight, though palatable enough. I am told that when Smyrna Figs sell for twenty to thirty cents per pound, Californian Figs bring but from five to ten cents. The tree comes into full bearing, where its location is favourable, in its third or fourth year; and ought to yield then about 60 lbs. of dried Figs, I am told. I suspect the cost of labour will control the drying of Figs, for they must be picked by hand. If they fall to the ground they are easily bruised, and the bruised part turns sour. They are dried in the shade, and on straw, which lets the air get to every part. Irrigation is not good after the tree bears, as the Figs do not dry so readily. Birds and ants are fond of the fruit; and in one place I was told the birds took almost the whole of the first crop. There are many varieties of the Fig grown in this State, but the White Smyrna is, I believe, thought to be the best for market. There are no large plantations of this tree in the State, but it is found on almost every farm and country place, and is a very wholesome fruit when eaten green.

When the farmers of the Sacramento Valley become tired of sowing Wheat, and when the land comes into the hands of small farmers, as it is now doing to some extent, it will be discovered that fruit trees are surer and more profitable than grain. This spring I hear a considerable emigration is coming into California, and I advise everyone who goes there to farm to lose no time before planting an orchard. Trees grow very rapidly, and it will be many years before such fruits as the Cherry, Plum, Apricot, or the raisin Grape are too abundant to yield to their owners exceptionally large profits.—(*New York Tribune*.)

GARDENING IN THE WEST.—No. 7.

TORTWORTH COURT, THE SEAT OF THE EARL OF DUCIE.

OVERLOOKING the picturesque vale of Berkeley, and commanding views of hill, wood, and water, stands Tortworth Court, the noble mansion of the Earl of Ducie, and of which the gardens and pleasure grounds are of high renown, both for their beauty and the skill with which they are managed by Mr. Cramb, whose reputation as a gardener is so well established, that it is almost superfluous to remark that what he does is well done, and that many a useful lesson may be derived from his practice. Tortworth is about three miles from the Charfield station of the Midland line from Birmingham to Bristol, and is easily reached from either of these towns, as well as from Bath; but from London the route is more roundabout, and it makes very little difference whether one travels *via* Stonehouse, Bath, or Bristol.

Tortworth is the Tortworth of Domesday Book; and passing over the Alwold, Turstin, Kingston, Le Veel, Matthews, Throckmorton, and Webb, who were successively lords of the manor, we find it recorded that the last named sold it in 1610 to Sir Robert Ducie, Bart., of whose descendants it has continued in possession. In 1661 Sir William Ducie had a license from the Crown to enclose Tortworth Park.

The mansion, of which we give a representation from a photograph by Messrs. Dutton, of Henrietta Villas, Bath, is in the Tudor-Gothic style, and was erected only a few years ago, the old house, situated near the church and the famous old Chestnut, having been pulled down all but some of the walls, which have been left as an Ivy-mantled ruin. The church, too, has been rebuilt, its God's acre added to, cottages built, with large gardens attached, which are let on the most liberal terms, and a co-operative store established, which proves a great boon to the cottagers, who are far from any good market.

The principal entrance to the mansion faces the east, and it will give an idea of the dimensions of the pile of buildings when we state that the central tower, which forms a conspicuous object in our engraving, is 130 feet high. The chapel on the right is now being pulled down; and although not strictly a gardening matter, we may remark that in one of the

rooms there is a very extensive geological collection, with many antiquities as well. The glass houses which are seen in our illustration consist of a corridor connecting the mansion with a stove originally intended for the culture of tropical fruits, but now containing grand specimens of *Latanias* and other Palms, and noble Ferns, of which *Cibotium Schiedeii* and *princeps* are particularly noteworthy, the fronds of the latter extending over a space of 20 feet in diameter. Flowering plants are introduced to give life and colour to the scene, and in winter the corridor is gay with *Camellias* and forced flowers of various kinds. It may be interesting here to note, that the Indian *Rhododendron Falconeri* had been fertilised with a deep scarlet hardy variety, and was seeding at the time of our visit. There is thus a prospect of a new race of this splendid shrub being either directly produced, or obtained indirectly by subsequent breeding. Outside, on one of the walls, is *Vitis polymorpha*, which forms a dense covering, and in autumn the leaves change to a glowing crimson. On the south side of the house is a geometric garden, in which the beds are filled with Savin, Ivy, Yew, *Cotoneaster microphylla*, and other subjects calculated to produce a dressed appearance at all seasons of the year. A blaze of colour is not desired, but bedding plants

are not neglected, as there is an ample display of them on the terrace. There is, be it said, a quietness and repose in the whole arrangement quite in keeping with the beautiful natural scenery which meets the eye in this direction where the lake is seen winding between two steep hills densely clothed with trees to the water's edge, presenting a landscape such as is to be equalled at few places in this country.

But before quitting the vicinity of the mansion for the lake side we will remark, that the park at Tortworth exceeds 1600 acres in extent, and that in the pleasure grounds surrounding the house, as well as in the park, are numerous fine Conifers, besides trees of other descriptions. The geological formation is somewhat varied, and Mr. Cramb, who has paid great attention to this subject and the effect of these variations on the growth of the trees, has made many interesting observations which it is to be hoped he will some day make public. He finds that all the Coniferæ succeed well on the red sandstone, but not on the lime; on this, however, the Deodar does well, so do the Elm and the Beech, whilst the Chestnut thrives best on the lias, and *Picea bracteata* and *Araucaria imbricata* luxuriate on the new red sandstone—one of the latter is 40 feet high. Of *Wellingtonia gigantea* we noticed several fine speci-

TORTWORTH COURT.

mens, one of them measuring 46 feet high, and what is remarkable, there was a fine tree planted in a depth of soil—limestone brash—not exceeding 10 or 12 inches. The Austrian Pine is here used to a considerable extent for shelter, and Mr. Cramb justly, we think, considers that perhaps no other tree is so well adapted for the purpose. It may be interesting to note, that in crossing the pleasure grounds a plant of *Acer rubrum* was pointed out to us, and on this the Mistletoe had established itself and was growing vigorously. There are several clumps of Thorns in the grounds, and no doubt when in flower these of themselves are a charming feature, for at the time they were planted every known species that could be had was obtained, and one of them (we regret to say we did not note its name), we were told, had flowered as early as February 1st. Before passing on to the lake we must add, that the pleasure grounds are not only diversified with clumps of shrubs, but with single specimens of Conifers, and that by constant attention to pruning these the individuality of each is carefully preserved.

We will now pass along the side of the lake—a piece of water covering some twenty-five acres, but long, and winding in the gorge between two steep hills, clad with a natural vegetation of Beech and Ash, and the sides broken with perpendicular and jutting rocks. On one side there is just the site for a charming *Rhododendron* garden, but by no means the soil, for it is limestone, and yet farther on there is a piece of ground of

quite a different formation, thrown up by some convulsion of Nature. Pursuing our way, with a Ferny bank on one side, the still lake on the other, we come to the remains of an old vineyard, with stone terrace walls still in tolerably good preservation, but the culture was given up owing to some dispute about tithes, and although the situation is high, yet as it faces south, and is well sheltered on the north, there can be no doubt that Grapes would ripen well in such a place, and quite well enough in any year for wine-making. Leaving the lake we pass to a place rejoicing in the suggestive but not inviting name of Bloody Acre, which is said to have been a place of fight between the Danes and Saxons, and as the position is good and there are remains of earthworks, it is not at all impossible that the Romans figured there as well; now, however, it is peaceful enough, and there are planted trees which Roman, nor Dane, nor Saxon ever saw, but which are the introductions of the race springing from all three (but mainly the last), from the old world and the then-undreamt-of new hemisphere. There the Deodar is luxuriating, *Cupressus torulosa* does fairly, but not so well as on the sandstone, and there are many others which are well represented; but the limestone, which forms the staple of the soil, as already remarked, does not appear to be favourable to Conifers.

Emerging from this place of former strife, and skirting the park, we overlook the farm, formerly in the occupation of the Editor of the *Agricultural Gazette*, but now in that of Mr. Cob-

ham, a Scotch gardener originally—a farm of 250 acres without a tree or hedge, and though such a state of things may be eminently unpicturesque, it must also be admitted it is eminently practical, and in this age of dear food and dear labour every inch of ground must be made productive, and man and horse power must be economised to the utmost. The day is coming when much of the labour of our farms will be done by steam, and for the profitable application of this fields will have to be made larger, hedgerows and pollards fewer. We should be sorry to see our picturesque winding country lanes give place to hard straight lines and wire fences, but there is many a straggling division between fields, choked with weeds and brambles, and useful neither as a fence nor shelter, which will have to be improved off the face of the earth. We omitted to mention in connection with the Conifers in the park that the largest *Pinus insignis* is 45 feet high; this escaped the severe frosts of the winter of 1860-61, but seventy-five trees of the same species were killed.

The old Chestnut to which we have already referred still exists, and though it has thrown-up a number of offshoots, it is, as may readily be supposed from its great age, in a very dilapidated condition. We were informed that there are his-

torical records of it as early as the middle of the eighth century, and Gilpin says that tradition relates that it was a boundary tree even as long since as the reign of King Stephen—that is, in the first half of the twelfth century, and if so, it must have been old even then, for saplings are not selected as boundary marks. When Gilpin saw it in 1808, Lord Ducie had lately released it from the garden-wall which pressed upon it, and enveloped it by the application of fresh earth to its roots. Even as late as 1788 it had produced great quantities of Chestnuts, small, but sweet and well-flavoured. Large as is this tree, it is far inferior in size to that upon Mount Etna, called the "Castagna de Cento Cavalli," or "The Chestnut tree of a hundred horses." It was 204 feet in girth, whilst that at Tortworth is not recorded to have exceeded 60 feet. Atkins, historian of Gloucestershire, writing in 1721, says there is a remarkable Chestnut tree growing in the garden of the manor-house, which tradition says was there in the reign of King John. In 1721 it was 19 yards in circumference, and seemed to be several trees incorporated, but this is not the fact, with other young growing-up. The ancient manor-house was near the church. Mr. Strutt ("Sylva Britannica"), gives an account of this tree which substantially agrees with the au-

THE TORTWORTH CHESTNUT.

thorities we have quoted, together with an illustration which we reproduce, as it conveys a tolerably accurate idea of the tree at the present day.

The fruit and kitchen garden, including a walled orchard of three acres, covers between nine and ten acres, and is a model of good keeping, while the trees, both on the walls and in the borders, are healthy and fruitful, neither over-luxuriant on the one hand, nor, on the other, presenting those signs of decrepitude and premature old age so frequently seen in gardens of this description. There are about seventy kinds of Apples, dessert and culinary, most of them trained in a bush form, branching at a yard from the ground. Nothing could be better than their appearance and that of the Pear trees, of which the varieties grown are equally numerous. Mr. Cramb has paid great attention to the selection of varieties suitable to the soil and locality, and as soon as it is discovered that any kind, whether new or old, is unsatisfactory, it has to give place to another. The result has been that we have here a choice and well-approved collection. The Pears, Plums, Cherries, and other wall trees, it need hardly be said, are excellently managed. In the open quarters standard Plum trees are also grown in rows between Currants and Gooseberries, whilst the borders by the side of the kitchen garden walks opposite the walls are occupied with bush Pears and Plums. On one of the walls are

a number of Mr. Rivers' new Peaches and Nectarines on trial; and in connection with these Mr. Cramb mentions that for years he had been much troubled with black fly, and that he had found Pooley's tobacco powder the only effectual remedy. The Apricot wall has a south-west aspect, but owing to the excessive rains from the Bristol Channel the crop proved unsatisfactory; a glass coping was then put up, but the result was no better, and now a hundred-foot run has been covered with a glass case 6 feet wide and 14 feet high at back, and a crop has been secured, as well as the certainty of others in the future.

In the two Peach houses and five vineries there are splendid crops. Mr. Cramb has worked Lady Downe's and West's St. Peter's on the Black Hamburgh stock, and finds that thus treated the berries of the former are not so liable to scald as when the Vine is on its own roots. He has likewise similarly worked the Muscat of Alexandria. There are, besides, two Fig houses, an orchard house, Melon and Cucumber houses, a Pine stove, and several plant houses and pits well filled and cared for. Mr. Cramb's house, in front of which is a small geometric flower garden, offers a marked contrast to the small, ill-ventilated dwellings which are still often found squeezed into some obscure corner of the garden, though happily their number is now growing fewer. It is spacious, with large rooms and plenty of them, and provided with every requisite accom-

modation, and an unlimited supply of water both hard and soft. We may remark that an accurate meteorological journal is kept at the gardens, and before closing this notice we will simply add that the pleasure of Mr. Cramb's intelligent converse, and the knowledge to be gained from his long experience which he freely communicates, would alone repay for a visit to Tortworth.

STRAWBERRY CULTURE.

It is altogether superfluous for Mr. Peach to state that he is an unbeliever in recognised theories, when the whole of the paragraphs preceding this statement plainly show that not only is he so, but that he has theories of his own which are totally at variance with the teachings of one's experience, and which are calculated to mislead those who are ignorant of the real requirements of this useful plant.

My standard of excellence is a high one, and I very strongly question if what Mr. Peach considers to be fine fruit would at all approach it. The statements to which he takes exception are no mere theories, but are deduced from considerable experience, and are therefore thoroughly practical, for I follow no beaten track if I can find a better one, and, like Mr. Peach, have tried old Strawberry beds side by side with new ones, always getting a plentiful supply of fruit, but with very few really fine berries, and that is why the term paltry is applied to it; for when the pristine vigour of a plant becomes so exhausted that its produce deteriorates in size if not in quality, it cannot fairly be said to continue in full bearing. Considering that the mode of culture requisite to produce Strawberries of the highest excellence is so simple, it is surprising enough that old and exhausted beds are still so prevalent, but it is far more extraordinary that anyone should be found to advocate such a state of things.

All Strawberry plants make fresh growth immediately after the fruiting season, whether manure is applied or not, and the ripening of the crowns follows this growth and does not precede it. It appears to me, therefore, that the best time to apply manure must be when growth is in full activity, and by forking the manure into the surface soil a store of rich nutriment is in readiness for the young roots, which seize upon it with avidity, hence the autumnal growth is so vigorous that the stout robust foliage passes through the severest winter almost unscathed. The application of mulching at so late a period of the year as October or November, confers no immediate benefit upon the plants, and can serve only to enrich the soil for a subsequent period of growth. Let both plans be compared, and I think conviction must follow that the period of active growth is the time to apply manure, and not when the plants are at rest, and I should certainly include such treatment under the category of untimely culture.—EDWARD LUCKHURST.

A MONUMENT OF TREES.

A SKETCH of the history of Thomas Hamilton, Earl of Hadlington, recounts his love of tree-planting, and the fact of the publication of a book "On Forest Trees," composed mainly of letters from his pen to his grandson. He is shown to be one of the most sagacious and enterprising of rural gentlemen, in the improvement of his domain, but loved the pleasure of the hunt too well. His wife took upon herself the fancy that trees could be planted and made to grow, and the author thus recounts the way she came to carry out her will:

"When I came," he says, "to live here (Tynninghame), there were not above fourteen acres set with trees. I believe that it was a received notion that no tree would grow here on account of the sea air and the north-east wind; so that the rest of our family, who had lived here, either believed the common opinion or did not delight in planting. I had no pleasure in planting, but delighted in horses and dogs and the sports of the fields; but my wife did what she could to engage me to it, but in vain. At last she asked leave to go about it herself, which she did, and I was much pleased with some little things which were well laid out and executed. These attracted my notice, and the Earl of Mar, the Marquis of Tweedale and others, admired the beauty of the work and the enterprise of the lady."

After her ladyship had succeeded in rearing several ornamental clumps, she proposed to enclose and plant the moor of Tynninghame, a waste common of about three hundred Scotch acres. The Earl agreed to her making the experiment, and, to the surprise of everyone, the moor was speedily covered with a thriving plantation, that received the name of Binningwood.

His lordship was tempted, by the success of these trials, to enter himself with great eagerness into the plan of sheltering and enriching the family estate by plantations. He planted several other pieces of waste land, enclosed and divided his cultivated fields with strips of wood, and even made a tract along the seashore called the East Links, which had always been regarded as a barren sand, productive of the finest Firs.

"And thus," says Mr. McWilliam, in his ingenious and useful "Essay on the Dry Rot and Cultivation of Forest Trees," "did her ladyship, to the honour of her sex and benefit of her lord and her country, overcome the prejudices of the sea and the barren moor being pernicious, and of horses and dogs being the best amusement for a nobleman; converting a dashing son of Nimrod into an industrious planter, a thoughtless spendthrift into a frugal patriot."

Thus can good wives in ev'ry station
On man work miracles of reformation;
And were such wives more common, their husbands would endure it;
However great the malady, a living wife can cure it.
And much their aid is wanted; we hope they'll use it fairish,
While barren ground, where wood should be, appears in every parish.

—(Horticulturist).

ARALIA SPINOSA.

UNINVITING as this tree assuredly is in winter, there are few who look upon it when well clothed with foliage but are impressed with its beauty and remarkable appearance. The extraordinary length of its finely-pinnated leaves, which are produced in sufficient number to give the tree a light, airy, and yet graceful appearance, seldom fails to attract attention; added to which are fine heads of bloom, frequently at a time when comparatively few trees present us with such a sight. The tree is also very hardy, and I do not think it at all particular as to the ground it is planted in; only, in consequence of the extreme size of its foliage, shelter from the highest winds seems advisable, for we occasionally find branches broken in summer from this cause, the wood being very brittle and the growth somewhat loose and straggling.

The tree would not be much of a favourite were it not for its magnificent foliage. A specimen we have been growing on a site not at all favoured, and which I have frequently measured, has foliage exceeding 5 feet in length up the stalk and leaflets together, and upwards of 4 feet in breadth, while the individual leaflets are not much larger than those of the common Ash. The leaf-stem is furnished with prickles here and there, which tend to protect it, for, unlike those on the woody stem, which are thickly set and stand out straight at right angles to the branch they are inserted on, those on the leafstalk are hooked inversely, but the latter are not very numerous, and present no impediments to the handling of the leaf by anyone exercising ordinary care. A full-grown leaf is generally admired by all to whom remarkable foliage has a charm, and having some slight resemblance to the fronds of some of our largest Ferns, it covers the greater portion of a good-sized table when spread out upon it. In general contour it is also flat, or rather with a graceful bend in the main leafstalk only; when laid down upon a flat surface its outlines are seen at a moment. The flower-heads form an irregular umbel of considerable dimensions, and are also elegant, usually making their appearance at the end of August or in September.

Taken as a whole, the tree is well worthy of a place in some sheltered corner, where its foliage has a chance of being fully developed. I believe the tree will withstand any amount of frost, but the wood is brittle, and the merest twig as thick as the human thumb. As it has but few branches, the tree when denuded of its foliage in autumn has not an inviting appearance; in summer, however, it cannot fail to please. I believe it is sometimes called *Aralia japonica*, a name by-the-by occasionally also bestowed on *A. Sieboldii*, which bears no resemblance whatever to the tree in question; but as they both come from Japan, the misapplication of the name is easily accounted for. Amongst deciduous trees having ornamental foliage *Aralia spinosa* may take a prominent place, and where a suitable position exists, the planter who wishes for novelty cannot well find anything more likely to fit his purpose, and I heartily recommend it.—J. RONSON.

PROTECTION OF POLLEN.

DR. A. KERNER reprints from the "Proceedings of the Medical and Scientific Society of Innsbruck" an interesting memoir on this subject. Pollen is of two kinds, powdery and

coherent. The former kind is found almost exclusively in those plants whose fertilisation is effected by the agency of the wind. The quantity of pollen is in these cases enormous; the anthers are frequently attached very slightly to the end of elongated filaments, so that the pollen is shaken out of them by the least breath of wind; the flowers grow on the most exposed parts of the plants, frequently appearing before the leaves, so as to give greater facility for the dispersion of the pollen, and are not provided with a brightly-coloured corolla, powerful scent, or nectar, for the purpose of attracting insects. Plants, on the other hand, whose pollen is coherent, are dependent on insect agency for its dispersion and transport to the stigma. It is therefore absolutely essential in these cases that some means should be provided for its protection from moisture, whether rain or dew, which would immediately destroy its efficacy, until such time as it may be carried away by insects. A variety of contrivances is actually found in nature for effecting this end, which may be classified under the following heads:—

1. Protection by portions of the pistil or stamens themselves, as in the petaloid stigmas of Iris.
2. By portions of the calyx and corolla; this occurs in an immense variety of forms.
3. By sheaths, bracts, or foliage leaves.
4. By periodic movements of the leaves of the perianth, as in the closing of flowers at night or in rainy weather.
5. By curvature of the axis, as in those numerous flowers the opening of which is always turned towards the ground at the period when fertilisation takes place.

From the examples adduced Kerner draws the general conclusion that the protection of the pollen against the injurious effect of premature moisture is the more perfect the smaller the number of flowers and of pollen grains in the individual, the greater their degree of coherence, and the more exclusively the flower is fertilised by insect agency. In those plants where the flowering extends over a great space of time, where the anthers in the same flower vary in the period of their dehiscence to allow the escape of the pollen, and where the number of flowers in an inflorescence is very large, the protection of the pollen against the influence of the weather is reduced to a minimum, as in Umbelliferae and many species of Cruciferae and Saxifraga.

Finally, Kerner draws the conclusion that those plants whose coherent pollen renders insect agency necessary for their fertilisation can only have existed in very recent geological periods; and those new species or varieties must necessarily have the advantage, and tend to become perpetuated, which possess superior advantages, in respect to the climate in which they grow, for the protection of their pollen from all injurious influences. The plants, the remains of which are found in the oldest geological formations, are generally of that class which do not require insect agency for their fertilisation.

NOTES AND GLEANINGS.

THERE is a very long account of the PINE APPLE NURSERY, Maida Vale, in a recent number of the *Morning Post*. The Nursery, it is stated, was originally founded for Pine Apple culture, but gradually included all kinds of nurserymen's and florists' produce. It is now in the hands of a company, who are carrying out extensive improvements.

— WE understand that the SNOW OF THE METROPOLITAN FLORAL SOCIETY at the Surrey Gardens has been abandoned, in consequence of a stipulated contribution of £100 towards the expenses not being forthcoming.

— THE increased consumption of FOREIGN POTATOES is remarkable. In the last seven months the value was £1,829,153, against £353,005 in the same period last year.

— THE GRAPE HARVEST IN FRANCE promises to be unusually fine this year. How large a share the vineyards take in the produce of the country, and to what an extent they form the wealth of all classes, we may judge from the fact that there are 2,300,000 vineyard proprietors in the Republic. In all the sunny land of France there are only eleven departments which do not grow the Vine; twenty cultivate the Grape for home consumption, and fifty-eight for export. Most of the fruit is intended for the wine presses; but the best dessert Grapes also come from France. The famous Chasselas of Fontainebleau, Royal Muscadine are grown in the two little townships of Thomery and Champagne, both in the neighbourhood of Fontainebleau. The vineyards there produce an annual crop of about 2,000,000 lbs., of which the capital consumes about 800,000 kilogrammes, while the rest is exported

to England, Austria, and even Russia. The trade in Grapes, foreign and home grown, amounts in value to several million francs a-year. This, of course, does not include Grapes used for wine.—(*Globe*.)

— PEACH CULTURE ON THE DELAWARE PENINSULA has developed with such rapidity in five years that it is unequalled in magnitude by any of the fruit sections of the world. The number of Peach trees now on the peninsula, as gathered from last reports, is 5,000,000—representing fifty thousand acres. The value of land devoted to Peach orchards averages \$50 per acre, and the average annual income does not exceed \$50, although in many cases \$200 or \$300 per acre are realised. Estimates from most reliable sources indicate that the Peach crop of 1873 will be about 2,500,000 baskets; half of the trees of Delaware, in the northern half of the State, have had their buds entirely killed the past winter. Were the entire number of trees on the peninsula to bear a full crop once, it would be fairly enormous. We sincerely hope these enthusiastic Peach-growers may have a most abundant crop, and then, after it is all over, sit down and reflect: Does Peach culture pay when everybody is going into it? We have felt so for several years, that too many trees were being planted, and Peach-growing for the next five years would not be even as profitable as devoting the same ground to Potatoes. The Peach crop also effectually spoils the sale of other fruits which ripen at the same time—so much so that growers of other fruits often wish there never was a Peach. It seems as if the Peach-growers did not make much money themselves, and did not allow others to make any also. Peach culture in Delaware is effectually overdone.—(*American Horticulturist*.)

— A GERMAN florist, in a high state of irritation, related his troubles in this way. He said:—"I have so much trouble not de ladies, ven dey come to buy mine rose dey vants him: hardy, dey vants doubles, dey vants him fragrant, dey vants him nice colour, dey vants him abery dings in von rose. I hopes I am not vat you calls von uncalled man, but I have sometimes to say to dat ladies, Madame, I never often see the ladies dat vas beautiful, dat vas rich, dat vas good temper, dat vas youngs, dat vas clever, dat vas perfection in one ladies. I see her much not!"

— AMERICAN newspapers have been discussing the question, Which of the earth's products employs the greatest amount of capital? The *New York Journal of Commerce* thinks the inquiry may be limited to three products—hay, cotton, and tea. The *Philadelphia Ledger*, not admitting this limitation, maintains that if it be just, hay, or rather grass, is the most important product. Cotton and tea are grown only in a few countries, but grass is universal. According to the census, the value of the farms in the United States in 1870 was, in round numbers, \$9,263,000,000; of the live stock on farms, \$1,525,000,000; of farm implements, \$337,000,000; the year's wages, \$310,000,000; making in all \$11,135,000,000 capital employed in agriculture. Now, how much of this is devoted to the grass crop? The hay crop of 1870 is reported at over twenty-seven million tons; and this, at half the selling price in the large cities, would be worth more than four hundred million dollars, a far greater sum than the aggregate home value of the cotton or any other crop. But a large portion of the grass crop is used on the ground. Live stock of the value of above 1500 million dollars were fed from it in that year, and, averaging their lives at five years, we have one-fifth of that sum as representing the grass fed to them in the year; the value of the animals slaughtered for food in the year was four hundred million dollars; the butter crop of 1870 was over five hundred million pounds, which at twenty-five cents amounted to 128 million dollars; 235 million gallons of milk, at only ten cents a gallon, add twenty-five million dollars to the value of the grass crop; one hundred million pounds of wool, at twenty-five cents, add twenty-five million dollars more; and fifty-three million pounds of cheese, at ten cents, over five million dollars more. We have thus a grand total of nearly 1300 million dollars for the hay crop and the products of grass consumed on the ground in 1870. But, as the animals producing the meat, butter, milk, cheese, and wool consumed other food besides grass and hay, the entire value of the "corn" and oats crop of 1870, estimated at 270 million dollars, is deducted; and this leaves one thousand million dollars to be credited to the hay and grass in that year, in which the reported aggregate of all farm products was \$2,167,538,658, this last sum being probably too high, as it includes additions to stock, "betterments," &c. According

to this estimate the value of the grass crop was two-fifths of the aggregate value of all farm products. It is inferred that two-fifths of the capital invested in agricultural pursuits was devoted to the grass crop. The *Lodger* says, "If any other of the earth's products can make a better show we do not know where to find it."

WORK FOR THE WEEK.

KITCHEN GARDEN.

At the earliest opportunity earth-up the Broccolis, Savoys, and all other crops that require it. Remove Peas that are mildewed immediately they are done with. Destroy caterpillars that infest the Brassica tribe before they do much mischief. Cut down the flower stems of *Artichokes*, and remove the dead leaves from the old plantations. Those made last season will probably now produce a few heads. Continue to plant-out *Cabbages* for Coleworts at every favourable opportunity. Prick-out the young plants intended for the main spring crop. The *Cucumbers* intended for house culture should now be potted into their fruiting-pots; the soil for the purpose should be composed of equal parts of loam, rotten dung, and leaf mould. A good drainage should be given, the health of the plants depending in a great measure on this point. Allow one or two shoots to grow to the fullest extent of the house before being stopped. Give *Kidney Beans* an abundant supply of water when they are in bloom if the weather is dry and hot, or most of it will drop off prematurely. Plant-out the thinnings of *Leeks* from the seed-bed as soon as the weather is favourable. This is a very useful culinary vegetable during the winter, particularly where soup is made for the poor during an inclement season. We have lately seen the Tripoli *Onion* of an amazing size from a sowing last autumn; it has done better than any other sort, of which there were several sown and planted-out at the same time. We, therefore, strongly recommend it to be sown immediately. The last sowing of *Turnips* for the season should be sown; as the weather is favourable for the purpose, thin the advancing crops. Keep the *Vegetable Marrow* plants well supplied with water during dry weather; cover the ground about them with short grass, or litter of any kind if that cannot be procured.

FRUIT GARDEN.

Proceed with making fresh plantations of Strawberries, choosing well-rooted runners or such as have been taken up and pricked-out in beds previously. It matters little whether they have been planted in beds or in rows, provided the plants have a sufficiency of room. The ground should be well trenched and manured, and if the soil is of a stiff nature the addition of a considerable quantity of gritty matter will be of advantage in keeping the ground open, as no spade ought to be inserted among them until they are finally dug down. For general purposes no sorts are preferable to Keens' and the Elton Pine, and by planting on different aspects they will furnish a very early and a very late supply. Some of the new sorts I have not seen, and of others, such as Myatt's British Queen, I as well as others have a spurious kind. Other sorts that I have under my notice are not comparable to the above two sorts when both flavour and productiveness are taken into consideration. Rows of beds intended to produce next season should have their runners removed and the plants thinned-out, that the buds left may be fully matured. By adopting the latter practice and surface-manuring, one planting will produce plentifully for a series of years; though this is not generally desirable, as it would interfere with the rotation of cropping. As Peaches and Nectarines now begin to ripen, it will be necessary to fix nets or mats to catch the falling fruit. A double row of stakes 3 feet long should be driven into the ground 1 foot at about 3 feet apart, one row close to the wall, and the other about 2 feet from it. To the tops of the stakes should be tied lightly the nets or mats, so loosely as to form an open bag; in this may be laid a little hay, straw, moss, or any other soft material. It must be supposed that I advise this plan to save gathering. The fruit is at all times best gathered by the hand, but by the strictest attention some will fall, and if no means be used to catch it, it will be inevitably bruised and spoiled. Gather Apples and Pears as they ripen.

FLOWER GARDEN.

Before the propagation of plants for turning-out is proceeded with to any material extent, it is as well that a proper arrangement be made as to what number of plants are required another season. To keep up the interest of a garden, especially if planted on the grouping system, requires some considerable skill and forethought to vary the scene in each successive year, so as to prevent the arrangement becoming monotonous. Thus, if warm colours prevail to any material extent this season, it would be as well to introduce a majority of cold colours next season, and to edge each bed of the latter with its complementary warm colour; indeed, the system of edging beds with contrasting colours imparts highly interesting features to the flower garden, and more especially to such beds as may be distributed over the lawn without any methodical arrangement. For these

reasons no plants are so well adapted as those which have variegated foliage, and for that reason a large stock of Pelargoniums should be provided. The best of these is Mangles's Variegated, the common and Golden-variegated, and the different varieties of the variegated Ivy-leaved Pelargoniums. The Rose-scented variegated is an interesting variety, as is also a very small-leaved variety called Dandy. This variety makes the neatest edging for a small bed of any plant that I am acquainted with. Of the Oak-leaved kinds, Moore's Victory is very neat. Rollisson's Unique also makes a fine bed, and the old Fair Ellen is not without interest. Attend particularly to the regulating of over-growths, especially in Petunias and strong-growing Verbenas. Keep them well cut-in, so as to form neat beds, and yet do not let there be any appearance of their having been cut. Mow, sweep, roll, and keep all neat and clean, and if there be any wormcasts on the walks, water them with lime water.

GREENHOUSE AND CONSERVATORY.

Pelargoniums that have been struck from cuttings early last March, and planted in the reserve garden early in June, should now be fine plants for flowering late in the autumn. Their first attempt at blooming in the open air has been checked, of course, and now, as their second flowering-buds are well formed, they may be taken up carefully and repotted. Some people commit a great error at this stage in putting such plants into heat at once. This should never be done. The grand point is to keep the leaves as free from excitement as possible until the roots get hold of the new soil. A cool close frame covered with canvas is the best place for them. Chrysanthemums and all other plants that are planted out for a summer's growth—a very excellent plan, should be treated in this way, and should not be allowed to remain in the ground too late. Keep the conservatory dry from this time, and little air is required, except for keeping down sun heat now that the growth of most plants is nearly over.

PITS AND FRAMES.

There are many of the new Verbenas that will force admirably through the winter with little heat; this is the time to get a supply for this purpose. The new *Veronica speciosa* forces well for early spring, and although nearly a hardy plant, will stand as much heat as an *Ixora*. The old *Luculia* is as much sought after as if it were a plant of recent introduction, a proof that it is not a long-liver under cultivation. It flowers freely in loam, but for pot cultivation, and in the hands of beginners, hardly any loam should be used; equal quantities of peat, leaf mould, and sand will keep it in good condition for years.—W. KEANE.

DOINGS OF THE LAST WEEK.

The season so far has been exceedingly favourable for out-of-doors work, still in many places work is not in a forward state. This can readily be accounted for by the fact that work could not be brought up in the spring owing to bad weather and the wet condition of the ground, and when work falls in arrear early in the season there is little chance of bringing it up again. Whenever work falls behind, and things in the garden are not in a satisfactory condition, the wise gardener will make a strenuous effort to get everything in proper order, instead of grumbling at every difficulty that comes in the way. It has been truly said that grumblers are seldom good at anything else, and young gardeners sometimes require to be reminded that if a little pressure requires to be put on in the summer months, there are also times in winter when days are short and things seldom require to be done in a hurried manner; also that it is for their credit as well as that of the head gardener that everything should be kept in the best order.

FRUIT AND KITCHEN GARDEN.

We have been preparing ground for sowing Onions. It is deeply dug and well manured, and will be in good condition to receive the seeds the first or second week of September. We mix with it a small quantity of Cauliflower seeds, the plants from which are planted out in hand-lights early in October.

We have been earthing-up Celery plants, and with us this is a matter requiring much care, as this useful vegetable keeps very badly in our soil. We tried cocoa-nut fibre refuse, thinking it would preserve the plants better, but this was worse—the rows where the fibre was used containing the smallest number of sound plants. After clearing away the small offsets round the bases of the plants a strip of bast was used to tie the leaves together at the top, and some dry soil placed round the stem with the hand, taking care that none of it rolled into the centre of the plant.

We have gathered the early Apples—such sorts as Irish Peach, Devonshire Quarrenden, Early Harvest, and Kerry Pippin. Red Astrachan and Early Margaret are now over. We are using two sorts of Pears from our young pyramids—viz., Jargonelle and Beurré Giffard. The first is well known as not only one of the best flavoured early Pears, but the most certain bearer. The latter is not so well known; it is, nevertheless, a

very fine variety. It is later by a week than Jargonelle; it bears freely on the Quince; the fruit is larger than that of the Jargonelle, more rounded, and though not quite so highly flavoured, it is quite distinct in this respect, and is a good sort for small gardens, not being a robust grower.

Many of the pyramid Apple, Pear, and Plum trees require to have the young wood thinned and cut back. We shall do this at our earliest convenience.

We have just finished planting out the Strawberry plants. It is late, but they were sorts that we could not get runners from earlier in the season, being seedlings and new varieties. We like to have them planted out by the second week in August at the latest. The earliest-planted sorts have had the runners cut from them, and are growing freely.

ORCHARD HOUSE.

We are now enjoying the fruits of our labours here. Most of the fruit are approaching ripeness; much has been gathered, and some of the latest sorts, such as Lady Palmerston and Salway Peaches and Victoria Nectarines, are quite green and hard. Bellegarde Peach is just in; Violette Hative is also in. This is certainly distinct from Bellegarde, being paler in colour, but in respect to quality one is as good as the other, and at the season when they ripen no other Peach that I know can equal them. We have also picked the American Peach Exquisite; this is the best yellow-fleshed Peach of its season, but is a shy bearer, and will cause disappointment if the blossoms are not set by using a camel-hair brush or shaking the trees twice a-day when in flower.

As the fruit is cleared off the pot trees, those requiring re-potting are attended to at once. The sooner the trees can be repotted after the fruit is gathered, the better certainty of a crop the following season. The potting should be performed in a careful manner, and the pots used should only be a size larger than those employed for the previous potting. The roots are considerably reduced, so that the trees have a tendency to flag, and would both do so and shed their leaves if they were not attended to by being syringed two or three times a-day.

FLOWER GARDEN.

We have devoted much attention to this department. The flower beds and borders had become considerably crowded, and the "ribbons" had grown into each other. The shoots out of place have been cut away, dead and decaying flower trusses have been removed, and everything made as tidy as possible. The flower beds are often neglected at this season, but it is as well to keep them as neat as possible, and remove decayed flowers and leaves periodically.

Bedding Plants.—We have put in all our cuttings of Pelargoniums; it is rather late for the more tender sorts, such as the Golden Variegated and Golden Tricolors, so instead of placing the boxes out of doors, as was done with the green-leaved sorts, we placed them in a small airy house by themselves, where the cuttings will strike root more readily. We shall not put in cuttings of Verbenas, Ageratum, or any similar plants until the second or third week of September. Centaurea candidissima we have put in, one or two cuttings in 60-sized pots, and the pots were placed in cold frames where the lights can be kept rather close for a few days, and the cuttings be shaded from bright sunshine. We seldom lose any cuttings, treating them in this way.

We have sown some Hollyhock seeds to produce flowering plants next year. We save our own seeds from the best sorts, and the batch of seedlings which we flower every year are much admired. Very few of them are in any way inferior to the parents, and they are not so much trouble as propagating named sorts from cuttings. The young plants are grown in boxes and kept in a cold frame all the winter, or they may be pricked out in the open ground and covered with hand-lights or a glass frame.

Lobelias.—Saved seeds of *Lobelia speciosa*, and sowed in shallow pans or boxes. To have an early and good display of this useful little bedding plant the seeds should be sown at once, and when the plants are old enough to handle prick them out in boxes about an inch apart. It is best to mark one or two of the best plants and those most suitable for the purposes for which they are grown, and save the seeds wholly from them; by these means a selected and improved strain is obtained.

Last night, Sunday, we had a terrific thunderstorm; the flashes of lightning were incessant, and the rain for more than an hour fell in torrents. The rain was gauged this morning, and 1.20 inch was found in the receiver. The atmosphere is close and hazy to-day. I hope it will not affect the Potatoes; no diseased ones have been found as yet in our neighbourhood.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

W. Cutbush & Son, Hightgate, London, N.—*Bulb Catalogue*.
Dickson, Brown, & Tait, 43 and 45, Corporation Street, Manchester.—*Autumn Catalogue of Dutch and French Flowering Bulbs*.

Downie, Laird, & Laing, Stanstead Park, Forest Hill, London, S.E., and 17, South Frederick Street, Edinburgh.—*Descriptive Catalogue of Dutch Flower Roots*.

H. Cannell, Station Road, Woolwich.—*Autumn Catalogue of Florists' Flowers, Bedding Plants, &c., for 1873*.

Alfred Legerton, 5, Aldgate, London, E.—*Wholesale Catalogue of Dutch and other Flower Roots*.

William Paul, Waltham Cross, London, N.—*Bulb Catalogue*.
H. Curtis & Co., Devon Rosery, Torquay.—*Descriptive Catalogue of Selected Roses, &c., 1873-74*.

B. S. Williams, Victoria and Paradise Nursery, Upper Holloway, London, N.—*General Bulb Catalogue—Catalogue of Fruit Trees, Roses, &c.*

F. & A. Dickson & Sons, 106, Eastgate Street, Chester.—*Catalogue of Dutch Flower Roots, &c.—Catalogue of Select Roses, &c.*

Sutton & Sons, Reading.—*Autumn Catalogue of Bulbous Flower Roots, Plants, Seeds, &c.*

John Matthews, Royal Pottery, Weston-super-Mare.—*Illustrated Catalogue of Pottery, &c.*

Lawson Seed and Nursery Company (Limited), 1, George IV. Bridge, Edinburgh, and Southwark Street, London, S.E.—*Catalogue of Dutch Flower Roots, &c.*

TO CORRESPONDENTS.

* * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

BOOKS (J. W. C.).—Sowerby's "British Plants" is a very high-priced book. We do not know where you can obtain a copy. (B. T. G.).—"Plans of Flower Gardens, &c." may be had post free for 5s. 4d., and "Sanders on the Vine" for 5s. 4d.

PARIS NURSERIES (G. Bouché).—Call on Messrs. Vilmorin, Andrieux, and Co., Quai de la Magisserie, and they will give you introductions.

FRUIT-TREE RENOVATING (Old Subscriber, B. E. House).—In reply to your query as to the old gardener being rewarded by publishing his mode of treatment in a pamphlet, we reply, as did our neighbour "Punch," on an equally precarious proposal—"Don't." If his mode is written and sent to us we will write to him or to you, and state truthfully whether we think it novel, or, if worth publishing, what we would give for the MS. to publish in this Journal. If we thought deprecatingly of it we would return the MS., and we need not add we hope, though we do, that we should not make any use of the communication. A pamphlet is too low-priced to pay for advertising, and without advertising there would be no sale.

CENTHALOTUS FOLLICULARIS (An Old Subscriber).—It is a greenhouse plant, therefore may be exhibited in a class for greenhouse plants.

TUBERS ON POTATO STEMS (W. W.).—They often are so produced. The cause, probably, is the blossoming, or production of tubers by the roots, being checked.

TIME FOR TRANSPLANTING ROSES (C. W.).—The third or last week in October is to be preferred, but they may be removed earlier if the roots are dug-up with care, if kept watered in dry weather, and the shoots not too much shortened.

SWAINSONIA SEEDLING (Flora).—We see no difference from the parent species.

PEAS (E. J., Lincoln).—We cannot undertake to name Peas from the pod alone.

ASPECT FOR GREENHOUSE (M. S.).—The best aspect for a greenhouse is south; the wall against which it is placed and forming its back must have the ends east and west. An east or west aspect would do for plants, but the south is far preferable, and as you have Vines in view, indispensable.

PROPAGATING ALYSSUM VARIEGATUM, GAZANIA SPLENDENS, AND AGERATUM (Alpha).—All are propagated by cuttings, which should be taken off now. Select short stubby shoots of young growth 2 or 3 inches long, cut them below the lowest joint, and insert them about an inch apart in pans or pots. The leaves should be removed from the lower part of the cutting for about two-thirds their length, that is, the depth they are to be inserted in the soil. The pots or pans may be prepared for the cuttings as follows:—Fill them a quarter their depth with drainage, over that place an inch-layer of the siftings of two parts fibrous light loam, and one part leaf soil, and to the sifted soil add a fourth of sand; mix and fill rather firmly to within three-quarters of an inch of the rim. Cover with half an inch thick of silver sand, water gently, and stand on one side for two or three hours before inserting the cuttings. After insertion water gently, and when dry place in a cold frame on ashes, and keep close and shaded from sun. They will root slowly but surely. After the beginning of September they will need to be placed in a mild, sweet hotbed, but from August up to September, and even the early part of the latter month, they root well in a cold frame, and are the sturdiest plants. They may be struck up to the middle of October in heat.

NOTED IN GREENHOUSE (The Anonymous).—It would no doubt, be a great help to the Pelargoniums and Fuchsias in spring to give them the benefit of a hotbed after potting. It would encourage free rooting and the breaking,

but we should only place them in heat for a time, and withdraw the pots from it as they advance. If you put in the tan in February, plunge the pots in it early in March. We should, after getting the plants rooted in their final pots, gradually withdraw them in May, and so that they might not experience a check. In winter it would not be of any benefit to the plants to have them plunged in a bed of warm tan, though it would not injure the Tricloris and other Pelargoniums, only keep the soil no more than moist. The Fuchsias would be worse of bottom heat in winter. The pots should not be sunk in the tan more than a quarter their depth, when it is 80 at 1 foot deep, half when it is 75, and fully when it is 65 to 70. It is beneficial to Pelargoniums in winter to be near the glass at all times, but they should be sheltered from powerful sun.

POLYPODIUM ITALICUM AND HOLLY FERN CULTURE (Edis).—The first-named we do not know. The Holly Fern (*Polystichum Lonchitis*) is difficult of cultivation, and does not thrive well under artificial treatment. It is a rock fern, and as such should have at least one-third of freestone mixed with equal proportions of sandy peat and yellow loam, the freestone in pieces from the size of a pea to that of a walnut. Good drainage should be given, and the plant placed rather high in the centre of a pot, and supported with pieces of freestone. Water freely when growing, keeping moist at all times, and place it in an airy place, shielded from bright sun, or a sheltered position on rock-work out-doors. It is found to do best in damp but slightly elevated situations.

CUCUMBERS NOT FRUITING (G. M. W.).—We are not able to account for the plants not showing fruit as much as those of your neighbour, but there must be something different either in the temperature, soil, or treatment. The preparation of the border seems right, also the temperature (65 to 70 at night, 70 to 75 by day without sun, 80 to 90 with sun and abundance of air), and we can only conclude you do not stop the shoots so as to induce fresh or bearing shoots. Stop when the shoots reach the wires. If the shoots resulting from the stopping do not show fruit before the sixth joint stop them, and so on at every sixth joint, or a joint beyond the fruit.

VERATRUM NIGRUM SOIL (H. H.).—It requires deep rich loam enriched with leaf soil, and to be moist and slightly shaded from sun.

KEEPING VEGETABLE MARROWS (E. W.).—We do not think they can be so kept that in winter they may be eaten as fresh vegetables. If there is such a method we should be glad to hear of it.

VARIOUS (P. T. B.).—The Libston Pippin Apple tree will not need any more pruning than that you have given it—viz., thinning-out the centre; all you require is to keep the branches from being too much crowded. The roots ought not to be interfered with; and if vigorous do not manure, but if weak top-dress with manure. You may increase your stock by grafting next March on the Crab stock if for standards, or the Paradise if for dwarfs. The stocks may be had of a size fit for grafting of most nurserymen. The Briar stocks you have budded should remain where they are another year, and then in November twelvemonths plant them in their permanent positions, or you may move them during the coming November, only they will be poor the first season. The ground should be trenched, and a liberal dressing of manure applied. We should take out the soil from the circles two spits deep; take the bottom spit away, and mix with the other some strong turfy loam and a quarter of leaf soil, and well-rotted manure and refuse, mixing and returning to the hole, raising it about 9 inches above the surrounding ground to allow for settling. The flower stems of the Peaches should be cut down after flowering close to the growth at the root, just above the young shoots. The distance from the stem at which to cut off the roots in root-pruning trees depends on the age and size of the trees. If they are old and large they should have a space of 4 to 6 feet left undisturbed, calculating from the trunk of the tree. On low walls and young trees 3 feet from the stem is a suitable distance. Your fruit trees on a stiff clay will need but little manure. We should add to it as much of the burnt earth, old lime rubbish, and refuse as you can spare, digging it into the soil, but not disturbing the roots. It is not desirable to cut away the roots of Gooseberry or Currant bushes, but it is well to remove the soil 2 feet from the stem all round to the roots, not disturbing them, and after a fortnight's exposure fill-in with manure, placing a little fresh soil on the roots. Apricots and Plums, which are the same as regards their roots, may have these laid bare, the space being filled up with fresh soil and manure. It would no doubt much invigorate them if weak, but we should not leave the roots exposed longer than could be helped. Gooseberries of large size are, red—London, Dan's Mistake, Conquering Hero; yellow—Levellor, Catherine, and Drill; green—Stockwell, Shiner, and Telegraph; white—Antagonist, Snowdrop, and Careless. Trench the ground two spits deep, and mix with it plenty of leaf soil, burnt earth, and refuse. The tank will be very useful, at least its contents, for applying to most kinds of vegetable crops, pouring it between the roots or alongside. There is no crop in a garden but when growing freely it will benefit. In case of the liquid being in its pure state, it ought to be diluted before use with six times its volume of water. When rain falls it will not need to be diluted. You must exercise judgment in this matter. It is better to apply it weak than strong. Do not fail to give the Asparagus as much as you can—a good soaking every ten days or a fortnight from June to the middle of September.

SEEDLING ORANGE CULTURE (Norvic).—The orange tree, if from a pip sown this year, will not require more than a 4-inch pot, and if not in one of that size we should shift into such at once, using a compost of light fibrous loam three parts, one part leaf soil or well-rotted manure, and a sixth of sharp sand. Drain the pot well, and water only when the soil is dry, then give a good supply. It requires a temperature in winter of 40 to 45, and in summer of 55 to 60 at night, 70 to 75 by day, and 80, 85, or 90 with sun and abundance of air. It will be many a year ere it fruit, unless it be grafted, and then it may be a fruitful plant in three or four years.

ANNUALS FOR SPRING BEDDING (Auntour).—Late in spring these do not flower sufficiently early to be off before the time of planting summer bedding plants. We name a few, with the colours of the flowers and usual height:—*Asperula azurea setosa*, blue, 1 foot; *Campanula pentagonica*, blue, three-quarters of a foot, and its white variety of the same height; *Candytuft*, crimson, lilac, white, all 1 foot; *Collinsia bartisifolia*, purple, and its variety alba, white, 1 foot each; *C. bicolor*, purple and white, 1 foot; *C. grandiflora*, purple, 1 foot; *C. candidissima*, white, 1 foot; *C. verna*, blue and white, 1 foot; *C. violacea*, violet and white, 1 foot; *Erysimum arkansanum*, yellow, 1 foot; *Euchiaridium grandiflorum*, red, and variety alba, both 1 foot; *Limnanthes Douglasii*, white and yellow, trailing, 3 inches; *Nemophila insignis*, pink, 6 inches; *Platystemon californicus*, yellow, 1 foot; *Silene penstula*, blue; *S. ruberrima*, rose, 9 inches; *S. alba*, white, 1 foot. They should be sown out-doors in the second or third week of September, and in October be pricked-out in light soil in a sheltered border, and moved to the beds in March. We prefer bulbs and spring-flowering plants to annuals. It is now too late to sow the spring-flowering plants.

PEAR MISFORMED (P. P.).—We have seen the same malformation. It is a multiplication of the calyx remaining permanently as a portion of the fruit's rind.

PARASITES OF CURRANT LEAF (J. W. Cobb).—The parasites on Currant leaves are the eggs of *Chrysopa abbreviata*, or some closely allied insect.—M. J. B.

INSECTS ON MELON PLANT ROOTS (S. W. S.).—The insects you have sent, found on the roots and stems of your drooping and dying Melon plants, do not appear to us to have been the causes of the mischief. We have found in the phal nine specimens of *Chelifer caucroides*, a species generally supposed to feed upon mites and other small insects, and one specimen of the little Beetle *Anthicus antherinus*, a still more harmless insect.—I. O. W.

CATERPILLAR ON APPLE TREE (Idem).—The smashed caterpillar found on the stem of your Apple tree is that of the Wood Leopard Moth full grown; it burrows into the wood of the tree, and is therefore injurious, especially if the tree is young. It also attacks other trees.—I. O. W.

BURNING CLAY (A. M.).—As you have tried in every conceivable way to burn clay and failed, we quote that given in the "Gardener's Assistant," as practised by Mr. Mechi. "The mode of raising and burning is this:—A strip of land is broken up in very dry weather with Ransome's Y L plough, drawn by three strong horses abreast a Scotch equilibrium whittle tree. So great is the resistance that it requires two men to hold the handles of the plough to counteract the leverage of the horses. The earth is thus broken, or I may say torn up in immense rough masses or clods, as much as a man can carry, which are admirably adapted to form walls and supports for the mass of fire. By this means heaps of nearly two hundred solid yards may be readily burned. The earth being ploughed-up the fires are formed on the spot, the workmen placing a certain quantity of dried stumps of wood of sufficient solidity to maintain a body of heat, and enclosing the mass with large clods. These are carried by hand; subsequently, as they get more distant from the fire, a barrow is used, and beyond that a one-horse cart. It is important to have the sides of the heap as upright as possible, not conical, because the heat always makes for the highest place. An important point in burning is to supply the fire sufficiently fast to prevent its burning through, and yet avoid overlying it, which might exclude all air, and put it out. Practice will indicate the medium. When the fire shows a tendency to break through, the outside of the burning mass is raked down and more earth added. If the ground is very dry, and no rain falls, the men are obliged to feed the fire almost constantly night and day; but when there is moisture it may be left for five or six hours, but seldom longer. Something depends on the current of air. A strong wind would blow the fire from one side and on at the other. This is guarded against by placing hurdles interlaced with straw as a guard to windward. The size of the heap is limited by the height to which a man can throw up the soil, and, of course, the diameter must be proportioned to the height to prevent its slipping down." Full particulars are also given for burning clay as practised by Mr. D. Thomson, when gardener at Archerfield, in *THE JOURNAL OF HORTICULTURE*, Vol. XXII, New Series, page 235; also the mode of burning clay at page 310 of the fifth volume of our first series.

CLETHRA ARBOREA CULTURE (Idem).—It is a greenhouse plant requiring to be grown in sandy fibrous peat three parts, and half a part each leaf soil and fibrous loam, with a sixth of silver sand. Afford good drainage, abundance of water when growing, and moisture at all times, but keep drier when at rest than in growth. A light airy position should be afforded.

PRICKLY-SEEDED STINACH (W. C. E. S.).—Any one of the principal seedsmen who advertise in our columns could supply to you the Flanders variety.

GRAPES WITHERED (Sussex, and C. E. B.).—They are severely "shanked," as gardeners term this mode of failure. The stalks are dead, consequently no sap is supplied to the berries. The usual cause is that the roots are kept either too cold or too dry; not knowing any of the circumstances we cannot give a further opinion.

TRANSPLANTING CEDRUS DEODARA (Peter Bridgford).—The *Cedrus Deodara* that is 7 feet high may be safely removed any time in November, or sooner if necessary. Lift it carefully from its present position, retaining a compact ball of earth of about 2 feet in diameter about the roots, wrap the ball securely in a garden mat, and then pack it in a basket or box with moss. Secure the branches with string and a mat. In replanting lift the position of the tree be raised somewhat above the surface of the surrounding soil, so that when the roots are covered it may appear to be standing upon a slight mound; water it thoroughly, covering the surface with some litter. Fasten the tree securely with wire attached to the stem, and to three stout stumps driven into the ground, equidistant, in the form of a triangle. See that it does not suffer from drought. Your rich light soil will answer admirably for it.

HEATING A GREENHOUSE (Idem).—Four rows, or about 130 feet of 4-inch piping, will suffice to keep frost out of a span-roofed greenhouse that is 32 feet long, 13 feet wide, and about 9 feet to the ridge.

FORMING A PINE WOOD (Sunny).—Finnis Lariole would, doubtless, answer well for planting three acres of ground on the side of a hill between two other woods of mixed deciduous trees, but as you require a dark thick wood we recommend *Pinus austriaca*. It grows to a large size, is very robust and hardy, and its numerous branches are densely clothed with dark green glossy foliage, so that a large mass of it has a rich and striking appearance. In planting such a wood, future thinning ought certainly to be contemplated, and to render such profitable we would plant the *Pinuses* 9 feet apart, fill the whole intermediate space with Larch 3 feet apart, the Larch to be gradually removed as the *Pinuses* required space; and we should certainly contemplate the removal of quite half the *Pinuses* in time. Thus much of the formation of a Pine wood. We cannot speak decidedly as to its future appearance, because the aspect of the surrounding features must very much influence this. If you fear that so large a mass of dark foliage will appear sombre, heavy, and monotonous, as it very likely will do in some degree, you might introduce some bold clumps of Scarlet Oak, Birch, Scarlet Maple, Norway Maple, Purple Beech, Fern-leaved Beech, and Aracia. A few clumps of such Conifers as *Abies Douglasii* and *Picea pectinata*, by their lofty growth, and distinct and elegant appearance, also answer admirably to impart a pleasing relief. We prefer November for planting, but you may safely venture to plant any time in October. Let all of the holes be made before the trees arrive, and the position of every tree should be decided upon, in order that no time may be lost in planting.

CLEMATIS JACKMANNI FLOWERLESS (Idem).—Your Clematises which have been planted two years, growing vigorously but failing to produce any flowers, are, doubtless, gifted with nutriment. Cease using manure water, and you

may yet obtain some flowers this autumn. You will not regret your failure next season, when you will probably have a profusion of fine flowers.

TREATMENT OF SEEDLING PEACHES (*Inquirer*).—Seedling peaches will bear fruit when three years old if grown in pots in the orchard house. They would be about two years longer if grown out of doors on a wall. Your trees will require to be cut back in the spring to within a foot of the ground; you will then train one leading shoot and two side shoots, and if the trees are grown on a system of summer-pinchling they will bear all the sooner.

COPING FOR KITCHEN GARDEN WALL (*Kamalia*).—Stone slabs are the best for this purpose. Ours are an inch thick, and project 3 inches over the wall.

FRUIT TREES FOR GARDEN WALLS AND ESPALIERS (*In Old Contributor*).—You ought to be a little more explicit in your questions, and should have told us what sort of fruit you prefer. We advise you to plant the espalier with Apples. The best sorts for your purpose would be Early Harvest, Cox's Orange Pippin, Kerry Pippin, Seckel Nonpareil, Reinette du Canada, Dumelow's Seedling, and New Hawthornden. On the west wall we would plant Pears. The following will be suitable—Beurre d'Amalnis, Madame Freyve, Beurre Superfin, Marie Louise, Doyenne du Comice, Brockworth Park, Gansell's Bergamot, Easter Beurre, Glou Morcean, and Bergamotte Esperen. On the east wall plant Apricots and Plums. Of the former Moorpark and Peach are the best. Plums—Green Gage, Kirke's, Cox's Golden Drop, Jefferson, Victoria, and Reine Claude Rouge. On the north wall Morello Cherries and Red Currants will be the only suitable trees.

MULBERRY TREE UNSUCCESSFUL (*H. N. O.*).—Old Mulberry trees bear most freely. Your tree seems to grow too strongly. Root-pruning would have a tendency to check this luxuriant growth, as the Mulberry bears freely when restricted to pot culture. Even young trees will do so. Do not prune the tree except to thin out the wood where it is too thick. We advise you to try root-pruning. Cut a trench round the tree at about 3 feet from the stem, and cut away all roots to the depth of 2 feet. You may also with a fork work under the ball and cut away any downward roots.

PELARGONIUMS FAILING (*Fidget*).—It is very difficult to judge what may be your cause of want of success from inspecting the leaves sent. Our impression is that, though the house is shaded, it has been kept too close and dry, and that the plants have not had sufficient moisture either at the roots or in the air. Neither of the sorts sent—Lass of Gowrie and Sir Joseph Paxton, is inclined to have large leaves; but still, Tricolor Geraniums under pot culture require liberal treatment, and during the summer months should be kept as cool and moist as possible without too much shade. There is no better way of growing Geraniums than in a cool frame with lights facing north, the glass slightly dulled with whitening and milk, and tilted so as to admit plenty of air, removing the lights altogether on dull days, but keeping the lights as protection against too much sun or heavy showers. The bicolor shoots on Mrs. J. Clifton, Italia Unita, &c., are merely spots without any of the green colouring matter, just as one occasionally sees perfectly white shoots on Alma, Byron, Miss Kingsbury, &c. You may syringe and water overhead as much as you like, provided the water is clean and pure. If overhead-watering were injurious to Tricolors, what would become of them when bedded-out? There is no time at which Tricolors have such beautiful colour as in the moist nights of early summer and again in the autumn.

LITTLE HEATH MELON.—Mr. Gall, Bradford Gardens, Dorchester, writes to say that he has cut three fruits of this variety, weighing respectively 7 lbs., 7 lbs. 2 ozs., and 7½ lbs., and that the vines are still in good health.

TRANSPLANTING RHODODENDRONS AND AMERICAN FIRS (*Quatt*).—Rhododendrons and all kinds of evergreen trees and shrubs are best moved in September, or from the beginning of October to the middle of November; but if they have been grown very closely together, and are on that account tender, no time is so good for moving them as the early part of April. They do not then experience the loss of the shelter close planting secures, and they have time to become established in their position before a return of cold weather, whereas if planted early in autumn they suffer very much if the winter be at all severe. Early-autumn planting we advise for subjects grown singly or thinly, and for those grown thickly plant in moist warm weather in spring. Rhododendrons lift well at all seasons, but it is advisable not to remove them when flowering and making fresh growths. The American Firs should be planted in February.

OLD PLANTS OF STRAWBERRIES OR RUNNERS (*Idem*).—If you take up old Strawberry plants, divide and plant them, they will not do any good. Runners only should be planted, taking them from plants that have borne fruit this season, or the fruitfulness of which is known. It does not answer to plant the runners of unfruitful plants.

MELONS GROWN (*J. W. L.*).—The hollows we should attribute to their having had too much water overhead, and too little at the roots. They have been kept too moist and cold. Give more heat and less water. Beaton's Indian Yellow has long been known and extensively used as a bedder. Mrs. William Paul is a good rose pink, but is not a good bedder; as a pink, Mrs. Upton is better, also Master Christine.

OLEANDER DROPPING ITS FLOWER BUDS (*J. B.*).—When growing and flowering this plant can hardly have too much water, three-parts of a pint being by far too little to give a plant with four blooms. It would only moisten the upper part of the soil, whereas all watering should be so given in quantity that the water reach the whole and moisten it throughout, showing itself at the drainage. On the other hand, the plant should give evidence of needing water before any is applied, and then a thorough supply ought to be afforded. Watering at stated times without taking into consideration the condition of the soil is bad.

SUCCESSFUL EMPLOYMENT OF SEWAGE (*J. Smythe*).—Practice and science agree in testifying that sewage is a most profitable manure. On light-soiled four hundred acres of mere rabbit-warren, at Mansfield, the Duke of Portland now grows most abundant crops of grass. If you write to his manager there he would give you full information; as will W. Hope, Esq., Irrigation Farm, Brompton, where crops of all kinds, horticultural and agricultural, are grown. There is also a large grass farm at Croydon, part of which is clayey, manured solely with sewage. At all those places the crops are very large and most probably grown. The sewage at all is applied in a liquid raw state by means of open channels. We know that no offensive odours or injuries arise from the employment of sewage, for the earth is one of the most effectual, as it is the most profitable, of deodorisers. The idea that sewage-manured grass causes disease to the animals fed upon it is baseless.

VINES ATTACKED BY RED SPIDER (*W. B. B. and A. F.*).—This is the most voracious and insidious enemy of the Vine, and they will always be attacked by it. The Vines when in a dormant state should be painted with a

mixture of tobacco liquor, sulphur, and soft soap; and if they are properly treated, red spider does not generally appear until the Grapes show signs of colouring, unless the pest has been introduced by plants growing in the house. It can be kept in subjection by syringing, but, as "A. F." complains, this destroys the bloom. We never syringe our Vines after the buds are started an inch, and we keep the red spider under by painting the hot-water pipes with flowers of sulphur, after the house is shut-up in the afternoon. The pipes should be so hot that it feels uncomfortable to place the hand upon them. "A. F." asks if syringing his Grapes until they began to colour caused the bloom to disappear, and also injured the white Grapes? No doubt it was the cause.

CARNATIONS AND PICOTEES (*A. Ledward*).—We must refer you to the reports of the Royal Horticultural Society's Shows, pages 44 and 57.

POTATO REFUSE FOR MANURE (*M. C.*).—When decayed it may be applied to any of your flower beds with equal advantage.

NAME OF FRUIT (*T. B.*).—The Apple is Red Astrachan. The Fuchsia is *F. splendens*.

NAMES OF PLANTS (*R. E. A.*).—We cannot name a Fern from a portion of a barren frond. (*North Rock*).—*Lonicera involucrata*. (*A. Z.*).—The herbaceous plant is *Galega orientalis*. 1, *Doodia lanulata*; 2, *Monstrum form of Athyrium Filix-foemina*; 3, *Aspidium aculeatum*; 4, *Nephrodium Filix-mas*; 5, *Polypodium vulgare*. (*D. G. Gurnsey*).—The "New Zealand Linsced" is *Linum monogynum*, the other is *Solanum Capsicastrum*. (*J. G.*).—Specimens unsatisfactory. The red-flowered one is *Physalis capensis*, that with a spike of white flowers is *Francoa ramosa*. (*Alida*).—1, *Hypericum hircinum*; 2, *Eucyonium japonicum variegatum*. (*B. F. W.*).—1, *Adiantum hispidulum*; 3, *Pteris serrulata*; 2, *Pteris serrulata cristata*.

POULTRY, BEE, AND PIGEON CHRONICLE.

BIRMINGHAM POULTRY SHOW.

The prize lists for the next Exhibition, which is fixed to be held on November 26th and the first four days of December, have been recently issued. The revision of the poultry schedule has not resulted in alterations more extensive than the introduction of Selling classes for Coloured (other than Silver-Grey) Dorking cocks of any age, the prices of which must not exceed £1 10s. each; for the same description of Dorking hens or pullets, the prices of which must not exceed £2 2s. per pair; for Dark Brahma cocks of any age, the price not to exceed £1 10s.; and for Dark Brahma hens or pullets, price not to exceed £2 2s. per pair. We are informed, however, that since this schedule was printed a silver cup, value £3 3s., has been promised for each of the four classes of Pouter Pigeons—one by Mr. F. Graham, Birkenhead, for the Blues; one for the Reds or Yellows by Mr. W. H. Mitchell, Moseley; and the others by a few subscribers.

The entries in all departments close on Saturday, November 1st.

DURHAM POULTRY SHOW.

The Durham County Agricultural Meeting took place on the 22nd inst. Fothergill's pens were used, and were neatly erected in single tiers. No member of the Committee exhibited, and in consequence some of the classes (notably the Cochins) were poor. *Brahmas* were good, the first adult birds, and the second chickens. *Dorkings* were a grand class, all the pens being good, but some of them out of feather. *Spanish* were poor; also the *Polands*, with the exception of the first-prize Silver. *Game* were really good throughout, the winners being Brown Red, while the highly commended pens were Piles and Black Reds. The Spangled *Hamburghs* in both classes were bad, but in Pencils there were some capital birds, the Gold-pencilled cock in the first-prize pen being as nearly perfect as possible. In *Game Bantams* the winners were Black Reds, the first a grand old pen, and the second excellent chickens of that variety, Piles being highly commended. In the Variety class of Bantams, Blacks were first and Whites second, and a pretty little pair of Nankins was very highly commended; in the next class, which was for any variety of large poultry, Houdans were first and Black *Hamburghs* second.

The class for *Rouen Ducks* was such as will not be easily surpassed at this time of year, and the winners were very large and good in all points, the Aylesburys being a good second to the above class.

COCHINS.—1, A. M. Bahner, Bishop Auckland. 2, D. & J. Abison, Whitby. *he*, T. H. Redman, Whitby; F. Horseman, York. *c*, W. J. Thompson, Woodhorn, Morpeth.

BRAHMA POULTRY.—1 and 2, R. Moore, East Rainton. *he*, F. Horseman.

DORKINGS.—1, W. J. Thomson. 2, J. White, Warkley, Northallerton. *c*, A. Buglass, Carville, Durham; W. Bearpark, Amlerby Steeple; C. Wulhas, Howden, Darlington (2).

SPANISH.—1, E. Moore. 2, A. Buglass. *he*, R. Elliott, Fence Houses; H. Dale, Northallerton.

POLANDS.—1, A. Buglass. 2, W. Bearpark.

GAME.—1, J. Fletcher, Stonehouse. 2, T. & J. Robson, Bishop Auckland. *he*, A. Buglass; J. Nelson, Coekshaw, Hexham; T. & J. Robson.

HAMBURGERS.—*Golden-spangled*.—1, A. Buglass. 2, W. Bearpark. *he*, R. Keenleyside, Bishop Auckland. *Silver-spangled*.—1, R. Moore. 2, G. Russell, South Hydon. *c*, G. Turnbull, Morpeth.

HAMBURGERS.—*Golden-pencilled*.—1, W. Atkinson, Bishop Auckland. 2, W. Bearpark. *he*, D. Cheyne, Morpeth; G. & J. Buckworth, Church. *c*, T. H. H. Robson.

GAME BANTAMS.—1, J. Nelson. 2, T. & J. Robson. *he*, J. Nelson; R. E. Ducker, North-rye, Kirtou Layby.

BANTAMS.—*Except Game*.—1, J. Nelson. 2, T. & J. Robson. *etc.* Rev. J. G. Milner, Bishop Auckland. *hc.* A. G. Mitchell.

ANY OTHER VARIETY.—1, Rev. J. G. Milner. 2, W. J. Thompson. *hc.* G. A. Tate, South Shields; R. Moore. c, T. H. Redman.

DUCKS.—*Rouen*.—1, J. Nelson. 2, C. Graham, Alnborough, Boroughbridge. *vic.* W. Simpson, Frosterly. *hc.* J. Nelson; W. Swann, Redington. c, Miss Jordan, Driffield; J. B. Errathwaite; A. M. Bahner. *Aylesbury*.—1, T. F. Carver, Langthorpe, Boroughbridge. 2, O. A. Young, Driffield. *hc.* Rev. J. G. Milner; C. Venables, Castle Eden. c, C. Venables.

JUDGE.—Mr. E. Hutton, Pudsey, Leeds.

HUNSLET POULTRY SHOW.

This Show was held on the 18th and 19th inst. in a large marquee. The use of Turner's pens was certainly the greatest improvement that has taken place since the establishment of the Show. There was, however, a mistake to which we would draw attention—viz., the filthy state of the birds on the second day, owing to the large quantity of sticky dough corn and water on the bottoms of the pens, and which might have been easily prevented by the engagement of an experienced poultry manager, and of such there are plenty in the locality.

The entries were very poor, many of the classes only having sufficient birds to carry off the prizes. *Dorkings* and *Spanish* were extremely good, and a pair of really good Buffs carried off the first prize in the *Cochin* class, the second going to very forward White chickens. In *Red Game* the winners were of the Brown variety, but not in good feather, and in the next class good Piles won. In *Hamburgs* the birds were good. The winners in *Bantams*, Black or White, were both of the former variety, though a capital pair of White was unnoticed. In *Game Bantams*, Duckwings were first, and Black Red chickens second. *Brahmas* were a fair class in both number and quality, but the *Turkeys* only moderate, while there were some good *Geese* of the Toulouse variety, but they having eaten their prize cards could not make out the winners. *Aylesbury Ducks* were pretty fair, and the *Rouen* very good, though in the moult.

Pigeons were a very small entry, but some of the winners were good specimens, notably the *Barbs* and *Pouters*. In the Variety class *Ice Pigeons* were first, and *Spots* second.

The *Rabbits* were poor in all respects, which is not surprising, as only 5s. and 2s. 6d. in two classes were offered for competition.

DORKINGS.—1, H. Beldon, Goitstock, Bingley. 2, J. E. Maude, Middleton Lodge.

SPANISH.—1, H. Beldon. 2, J. Powell, Bradford.

COCHIN-CHINA.—1 and 2, H. Beldon.

GAME.—*Black-breasted or other Reds*.—1, H. Beldon. 2, E. Ackroyd, Ecclehill, Leeds. *White or Piles*.—1 and 2, R. Walker, Gomersall.

HAMBURGS.—*Gold-pencilled*.—1 and 2, H. Beldon. *Silver-pencils*.—1 and 2, H. Beldon. *Gold-spangled*.—1, H. Beldon. 2, J. Newton, Silsden. *Silver-spangled*.—1 and 2, H. Beldon.

POLANDS.—1 and 2, H. Beldon.

BANTAMS.—*Black or White*.—1, J. Waddington, Gaisley. 2, H. Beldon.

GAME.—1 and 2, W. F. Entwistle, Westfield, Bradford.

BRAHMA POOTRAS.—1 and 2, H. Beldon.

TURKEYS.—1, Lady F. Hawkes, Womersley Park, Pontefract. 2, J. Andrews, Rothwell Ham.

GEESE.—1, H. Kellett, Hunslet.

DUCKS.—*Aylesbury*.—1, J. B. Britton. 2, W. North, Leeds. *Rouen*.—1 and 2, J. Newton.

PIGEONS.

CARRIERS.—1 and 2, E. Horner, Harwood.

ANTWERS.—1, E. Horner. 2, G. Crann, Leeds.

OWLS.—1, J. Thresh, Bradford. 2, E. Horner.

TURBITS.—1 and 2, E. Horner.

BARBS.—1 and 2, E. Horner.

TUMBLERS.—1, E. Horner.

FANTAILS.—1, J. F. Lovelandside, Newark. 2, E. Horner.

POUTERS.—1 and 2, E. Horner.

NUNS.—1 and 2, E. Horner.

JACOBS.—1 and 2, E. Horner.

DOVES.—1 and 2, J. Bower, Hunslet.

ANY OTHER VARIETY.—1, J. Thresh. 2, J. Taylor, Leeds.

RABBIT.—*Long-eared*.—2, J. Armstrong, Leeds. *Any other variety*.—1, G. S. Burton. 2, G. A. Bowker, Hunslet.

JUDGE.—*Poultry, Pigeons, and Rabbits*: Mr. J. Dixon, North Park, Clayton, Bradford.

CHORLEY POULTRY SHOW.

The Royal North Lancashire Agricultural Society held their meeting last week at Chorley, and the poultry then exhibited proved a very great success. The inhabitants generally had taken every pains to add to the popularity of the Show, and had decorated most profusely all the principal streets with flags and banners; three triumphal arches made of wood, but artistically painted to resemble granite, formed a conspicuous feature, having the appearance of long-erected structures. Evergreens and flowers in abundance met the eyes of all visitors, and as the day proved enjoyable, the attendance of holiday-seekers by extension trains was beyond precedent. The poultry Show consisted of three divisions—viz., for old birds, for chickens of 1873, and for residents only of the Chorley district. The latter portion may justly be pronounced a failure, as the competition was very poor indeed as a whole, and in fact one-half the classes could not boast of a single entry. We can only hope, now that the inhabitants of Chorley have seen the fine collection of domestic poultry sent from all parts of the kingdom in the

other portions of the Show, it may stimulate them to personal exertions in poultry culture, whether viewed only as a recreation or as a profitable pursuit. The show of adults, though abounding in first-class fowls, necessarily lost much of its interest from the generality being heavily in moult. *Grand Dorkings*—both *White* and *Grey*, *Brahmas*—the best in the kingdom, and *Spanish* and *Game* fowls of equal note were abundant. Excellent classes of *Hamburgs*, more especially the *Black*, deserve notice. The *Geese*, both old and young, were of unusual size, and well shown; the *Rouen Ducklings* being no less noteworthy. The *Variety Duck* class proved a remarkably good one, among them being entered no less than three pens of *Whistling Ducks* and two pens of *Kasarks*, all of them in exquisite feather. The public thronged in front of this class during the whole of the time the Show was open.

The second division of the Show, exclusively for chickens, was a triumphant success, and the winners in every instance secured their laurels only under a very heavy competition. Where all were so thoroughly good it appears almost invidious to particularise, but perhaps the most noteworthy were the *Buff Cochins* of Messrs. Robinson and Sidgwick, and Mr. Brierley's *Brown Red Game* fowls. The *Waterfowl* shown in this division were extraordinarily fine.

DORKINGS.—*Grey*.—1, J. Stott, Healey, Rochdale. 2 and *hc.* J. Robinson, Garstang. *White*.—1 and 2, J. Robinson. *Any colour*.—*Cock*.—Prize, J. Robinson.

BRAHMA POOTRA.—1 and 2, T. F. Ansdell, Cowley Mount, St. Helen's.

SPANISH.—1, J. Leeming, Broughton, Preston. 2, H. Wilkinson, Earby, Skipton. *hc.* G. Pickering & J. Dugdaley, Driffield.

GAME.—1 and 2, C. W. Brierley, Middleton, Manchester. *Cock*.—1 and 2, C. W. Brierley.

COCHIN-CHINA.—1, Aspden & Newton, Church. 2, T. F. Ansdell.

HAMBURGS.—*Golden-pencilled*.—1, J. Bowness, Newchurch. 2, J. Robinson. *Silver-pencilled*.—1, J. Robinson. 2, J. Bowness. *Golden-spangled*.—1 and *hc.* J. Robinson. 2, J. Bowness. *Silver-spangled*.—1 and 2, J. Robinson. *Black*.—1 and 2, C. Sidgwick, Keighley. *hc.* J. Robinson; J. Bowness.

BANTAMS.—1, H. B. Smith, Brooklands, Broughton, Preston. 2, T. Barker, Hill End, Burnley. c, J. R. Robinson, Sunderland.

POLANDS.—1, G. W. Hibbert, Godley, Hyde, Manchester. 2, J. Arshworth, Burnley.

ANY OTHER VARIETY.—1 and 2, J. Robinson (*Creve-Coeur* and *Silver-spangled*) Poland. *hc.* J. Harrison, Cottam, Preston.

GEESE.—1, J. Walker, Rochdale. 2, S. H. Stott, Fishergate, Preston. *hc.* J. Grimshaw, Eccleston, Chorley.

DUCKS.—*Aylesbury*.—1 and 2, J. Walker, Rochdale. *hc.* J. Robinson, Garstang. *Rouen*.—1 and 2, T. Wakefield, Golborne, Newton-le-Willows. *hc.* J. Walker; S. H. Stott, Preston. c, J. Harrison; W. Penny, Preston. *Any other variety*.—1 and 2, H. B. Smith (*Whistling* and *Ruddy Shell*). *hc.* H. B. Smith (*Whistling*); J. Walker (*Whistling*); W. Binns, Pudsey, Leeds (*Kasarka*).

TURKEYS.—1, J. Walker. 2, L. Anyon, Whittlefield-Woods, Chorley.

CHICKENS.

DORKINGS.—*Grey*.—1 and 2, T. Statter, Whitefield, Manchester. *hc.* J. J. Walker, Kendal (2); J. Robinson. *White*.—1 and 2, J. Robinson.

GAME.—1, P. P. Lyon, Liverpool. 2, T. Dyson, Halifax. *hc.* W. Parker, Booth, Carnforth; T. Dyson.

COCHIN-CHINA.—1, J. Robinson. 2 and *hc.* C. Sidgwick.

HAMBURGS.—*Golden-pencilled*.—1, E. Clayton, Keighley. 2, J. Robinson. *hc.* J. Bowness, Newchurch. *Silver-pencilled*.—1, J. Robinson. 2, H. Smith. *Golden-spangled*.—1, J. Robinson. 2, No competition. *Silver-spangled*.—1 and 2, J. Robinson.

BANTAMS.—1 and c, T. Sharples. 2, T. Barker, Burnley. *hc.* J. Woods and Son, Accrington.

GEESE.—1 and 2, W. Penny, Preston. *hc.* J. Walker (2); S. H. Stott (2).

DUCKS.—*Aylesbury*.—1, J. Walker, Rochdale. 2, T. P. Carver. *hc.* T. Tomlinson. *Rouen*.—1 and 2, J. Harrison, Cottam, Preston. *Any other variety*.—1, J. Walker. 2, T. Wakefield.

LOCAL CLASSES.

SPANISH.—Prize, J. Whitfield, Chorley.

DORKINGS.—Prize, J. Thom, Birkacre, Chorley. *Chickens*.—Prize, J. Thom.

GAME.—Prize, L. Anyon, Chorley.

HAMBURGS.—*Silver-pencilled*.—*Chickens*.—Prize, T. Wainisley.

BANTAMS.—*Chickens*.—Prize, L. Anyon.

GEESE.—Prize, L. Anyon.

DUCKS.—*Aylesbury*.—Prize, Rev. J. Sparling, Chorley.

TURKEYS.—Prize, L. Anyon.

The Judges were Mr. Edward Hewitt, of Birmingham, and Mr. Joseph Hindson, of Liverpool.

THE RABBITS AT ROCHDALE SHOW.

There was a grand show of Rabbits at Rochdale Show, nearly eighty pens competing, and the awards gave general satisfaction. Mr. Boyle won with a grand buck, measuring over 20 inches by 5 inches, Lop-eared; and Mr. Easton won in does. In Himalayan, as a matter of course, Mr. Whitworth won, but was very closely pressed by Mr. Ball. The cup and first prize in the Angora class were awarded to Mr. Ball. Mr. Boyle won in the Dutch class with a grand buck that ought never to be beaten. Mr. Irving took second with one of Mr. Boyle's breed. For the heaviest Mr. Brown was first with a good Rabbit, weighing over 14 lbs.; E. E. Roys, Esq., second with a most promising heavy Rabbit. The best Rabbit exhibited was shown in the Selling class by E. E. M. Roys, Esq., and it won the cup against seventeen competitors. In its class it must have won as a Silver-Grey. Mr. Boyle won first in Silver-Greys, Mr. Roys being second.

Mr. Ridpath, of Outwood Hall, Handforth, was the Judge.

ISWICH POULTRY SHOW.—The eighth Exhibition is to be held on October 14th and 15th, with increased attractions in the way of Cats, Rabbits, butter, eggs, and dead poultry; the latter we do not think has been so much encouraged as it deserves to be, and we strongly advocate the offering of such prizes. There

are upwards of sixty classes; a silver cup or special prize is offered for almost every class, and the entry fee is reduced to 4s. and 3s. We understand that Mr. Hewitt has been retained as one of the poultry judges, and other competent gentlemen will be engaged according to the number of entries.

NORTHERN COUNTIES COLUMBARIAN SOCIETY.

This Society held their annual competitive Show of young Pigeons at their club room, at the Cathedral Hotel, Manchester, on Monday, the 18th inst. There were upwards of one hundred pairs competing, each exhibitor paying 2s. 6d. for every entry, and the amount of entry in each class was given to the successful exhibitor in one first prize. The Pouters, Carriers, Short-faced Tumblers, and Foreign Owls were not numerous; most of the prizes in these classes going to Mr. Towerson. There was a grand display of Barb's; the first prize went to Mr. Magnall. For Dragons Blue, and Any other colour, the prizes went to Mr. Holland. There was a grand show of English Owls and Fantails, the first prize in each class being awarded to Mr. T. Ridpath. Mr. Roysd won in Jacobins with a splendid pair of Blacks, which must be heard of again. The best Turbits were from Mr. Ridpath, and this was the largest class in the Show. In Long-faced Antwerps Mr. Appleton won with a pair of good birds; in Short-faced Antwerps Mr. Justice won with a beautiful pair. For Baldpates the first place was taken by Mr. Unsworth, and in Any other colour of Tumblers by Mr. Hyde.

Altogether the Show was a great success, and many thanks are due to Mr. Haycroft and the Committee for the very able and perfect arrangements. Mr. Hawley, of Bingley, was the Judge.

PIGEONS AT HITCHIN AND EXETER SHOWS.

Our correspondent justly remarks that it must have surprised more people than himself that his five pens of birds took first and second honours at Hitchin, and Mr. Yardley's were highly commended; but at Exeter, a few days later, the same Judge to the same competing birds reversed nearly exactly his awards. We add our correspondent's remarks upon other matters.

It is well known that dealers are the principal supporters of all shows in the three kingdoms, and are compelled to procure birds at fabulous prices to please the tastes of those gentlemen who are selected as judges, for dealers too well know that advertising prize strains for sale will not deceive fanciers now-a-days, as there are too many good judges amongst amateurs to purchase before seeing the birds, and they prefer birds that have given proof of their quality by winning in good company before they will purchase; and too often have dealers to purchase birds to suit the fancy of certain judges, although well knowing at the time the same bird or birds to be greatly deficient. Still, to please the judge and win the dealer must procure the bird or birds, and in the event of those identical birds being purchased from the dealer for the purpose of being again exhibited, and the same come under the judgment of a man who knows their deficiencies, he, of course, passes them over. Then goes a letter to the dealer from the purchaser, giving him to understand that he has deceived him; and should he not do so, he, doubtless, makes it worse for the dealer by quietly telling his friends that he bought so and so from so and so, and was worsted. Take an example: Had I sold those birds I won with at Hitchin, and the purchaser had shown them at Exeter, and if the purchaser was no judge of the quality of the birds, I wonder what sort of letter I should have received! I am afraid not a very flattering one. Still, such cases have often happened with dealers, and often the dealer thus loses a good customer. So I do hope that secretaries and committee-men will endeavour to ascertain who are the proper men to select to officiate as judges; and I believe the best plan to adopt to satisfy exhibitors and find out the best judges would be to let exhibitors vote for the man they consider the best judge, the most votes to prevail.—ROBERT FULTON.

OXFORD POULTRY AND PIGEON SHOW.—The prize list is largely and liberally increased. There are forty silver cups and pieces of plate, one of them given by Prince Leopold; and the money prizes, three in each class, vary from three guineas to ten shillings. The classes are increased to forty-three for poultry, and to twenty for Pigeons.

SHOW OF HONEY AT BURTON-ON-TRENT.

THE readers of our Journal, I have no doubt, will be glad to see recorded the results of the show of bees and honey at the flower show at Burton-on-Trent. The show was not up to the two last shows in the Bee class. There was one beautiful glass super which would have deserved the first prize had it not been for one comb having some brood. It was, I think, the best class

I saw this season. I am sorry to say the season here (South Lancashire), has been the worst I have known since 1860. Several of my friends have lost many stocks, not thinking they would be dying of starvation in August. I have sixteen stocks in the heather, which are looking well, but if the weather do not improve soon it will be all over for 1873. We are expecting a good show at Manchester, in September, at the Botanic Gardens; and I understand there will be a new design of bee hive, with bees at work, but I am afraid the show of honey will be light.—SOUTH LANCASHIRE BEE-KEEPER.

PRACTICAL BEE HIVE.—1 and 3, G. Cross, Burton. 2.—Young, Horninglow. **SUPER HONEY.**—1, G. Cross (42 lbs.). 2.—Young (21 lbs.). 3.—Sylvester, Barton-under-Needwood.

COTTAGERS' CLASS.

HUMAN BEE HIVE.—1, T. Pegg, Dallow Street. 2.—Smith, Doveridge. 3.—Murdolton, Kepton.

SUPER HONEY.—1 and 4.—Withnall, Rangemore. 2, E. J. Draper, Newton Road. 3.—Smith.

JUDGES.—Mr. Spencer, of Stourbridge; and Mr. Cooke, of Denton, near Manchester.

THE HONEY SEASON, 1873.

I AM very much surprised, at the same time rather pleased, to find that experienced bee-keepers complain of the scanty harvest this season. I say I am rather pleased, because it is a proof to me that my own deficiency does not arise from bad management.

I commenced bee-keeping last year with one hive, which of course I was very careful in feeding, &c. They sent out a fine swarm on the 29th May, almost the only May swarm in this neighbourhood. About a week after sending out the swarm I placed a cheese-box underneath, in which the bees constructed three medium-sized combs. To my deep regret I had disturbed the box, and taken it out from beneath before I discovered the combs. I then placed the combs in an old hive cut down at the top. They appear to have gone on making combs, but to have gathered no honey for filling. The swarm worked exceedingly well, and in a month's time had sealed-up a good deal at the top, and commenced building in one of Pagden's glass supers. They appear to have half filled the latter and begun to seal.

I beg now to ask you what you would recommend me to do. About a mile from my house is an extensive common covered with heath. I am of opinion that my supers should be left on until the end of September in expectation of the bees obtaining a good supply from the heath, and, failing that, allowing them to withdraw what stores they have in the supers, so as to be abundantly supplied for the winter. Do you think the distance too far?—WOLLASTON.

[No. Let them remain untouched till the end of September. Your plan is excellent.—EDS.]

THE BEE SEASON IN SOUTH DEVON.

MR. GEORGE FOX, of Kingsbridge, states, in a letter to me, that his experience this summer has been much the same as my own and that of others who have written on the subject, particularly with respect to the profligate breeding which has been carried on in supers. He writes: "I never had so many swarms from the few stocks with which I started, or had my supers so much bred in. The queens have always been in them when removed. On the whole I have had no cause to complain. Six supers have been worked, mostly square boxes with glass sides and top. The first taken off was full of honey (about 35 lbs.) and brood, and the queen was in it. This I keep as a stock, and it makes a good one. Brood-comb was supplied to the old stock from which a queen was raised. The next super, being much in the same condition, was also kept as a stock. Another super gave 25 lbs. or 30 lbs. of honey; it had a little patch of brood; the queen also being up in it, I caught and returned her to the old stock. I had three or four other supers, some of which are kept as stocks, the others for honey."

Mr. G. Fox also says that the bees of many of his stocks exhibit their descent from his original Egyptian queen presented to him by the late Mr. Woodbury. Though the Egyptian blood has been much "diluted," some of the bees are as well marked as were those of the original stock. They are very quiet, and he has required no bee-dress or gloves in any of his operations this season, even in transferring combs and bees from boxes into observatory hives. This amiable character does not agree with my own experience of the true Egyptians, which were perfect savages; but it must be remembered that Mr. G. Fox is a king or conjuror among his bees, and would seem to bear a charm which enables him to handle them with impunity.—S. BRVAN FOX, *Exeter*.

A GOOD HARVEST DRINK.

LAST summer we attended a field trial of ploughs, and for a drink in the fields we had buckets of cold water with oatmeal stirred in, which we found to be both victuals and drink, and

mighty refreshing. A Scottish medical journal also says of oatmeal, that in its raw state, when it is mixed up with water, it is becoming a favourite dish. The brose of "Auld Scotland" is becoming a favourite dish with the hunters and trappers of the West, who are substituting oatmeal in this form for parched Indian corn. The same brawny fellows have found out that a very acceptable drink is made by putting about two teaspoonfuls of oatmeal to a tumbler of water. This the hunters and trappers aver to be the best drink they can use, and it is at once nourishing, unstimulating, and satisfying.—(Ohio Farmer.)

[The addition of oatmeal to water for quenching thirst may be a discovery which the American hunters have recently made; but it has long been known in this country to the workmen in foundries and other places where men are exposed to fierce heat. Indeed, in some places, there is, or was till recently, a money allowance for the purpose.—Eds.]

CUPS FOR SILVER-GREY DORKINGS.

I HAVE just been informed by the Secretary of the Crystal Palace Poultry Show, that unless a cup for adult Silver-Grey Dorkings be given by private subscription they will be obliged to curtail the classes for this breed. This would be a great pity, and I therefore offer 10s. 6d., if nine other fanciers will give the same sum, to procure a five-guinea cup for the best Silver-Grey Dorking adult, cock or hen. I may also mention that I am collecting for a cup for Nankin Bantams at the same Show, towards which the subscriptions at present given are—Mr. Pigott, 10s. 6d.; Mrs. Cross, 5s.; O. E. Cresswell, 10s. 6d.—O. ERNEST CRESSWELL, *Early Wood, Bagshot, Surrey.*

OUR LETTER BOX.

FEATHERS ON HONDANS' EGGS.—FOWLS FOR TABLE (*An Inquirer*).—Almost all Hondan chickens have the stubs of feathers on their legs. They never grow to feathers. If they did they would be a disqualification, and might raise doubts as to purity. To show that it is immaterial, we may add that the same thing frequently occurs in Dorkings. They must, however, never go beyond being stubs. In that state we view them merely as sports, just as in the same family one man may be hirsute and another smooth-faced. Hondans are a hardy and excellent fowl. They will answer your purpose if you are content to submit to the expense and inconvenience of buying broody hens to enable you to keep up your breed, as the Hondans do not sit. We think Brahmans would suit you as well in other respects, and save you the last particular, being good sitters and mothers.

BRAHMAS—BUCKWHEAT AS POULTRY FOOD (*C. S.*).—We do not think the result of your hatching proves anything about Brahmans in general, but in your case it speaks badly for the strain from which you had your eggs. We should say it is decidedly an impure one. A single comb in a Brahma is a decided disadvantage. We consider buckwheat bad food for fowls. Good honest ground oats or barley slaked with water, with occasional feeds of whole corn or maize, are all that are necessary for good feeding. The new and modern introductions tend only to disease and disappointment.

SOUTHPORT AND ORMSKIRK SHOW (*H. Whibley*).—The Secretary having duly acknowledged receipt of the entry fee, but not having sent the usual printed label, nor answered your inquiry if you might send the birds without a label, will, of course, return the entry money. Write to the Secretary again.

ARTIFICIAL HATCHING (*H. T. K.*).—If we obtain a drawing of Mrs. Cheshire's "artificial mother" we will have it engraved. All experience is against the use of incubators.

NETT'S HIVE (*C. M. D.*).—Write to those who advertise hives in our columns. They all make those hives.

SCARCITY OF HONEY (*Killington*).—You are no doubt correct in your opinion, that the cold weather of the early part of summer had much to do with the scarcity of honey in your neighbourhood, as elsewhere.

VARIOUS (*A Young Apiarian*).—The brood you wish to save would not survive three, or even two days' chill and starvation if in open cells. Remember the voracity of all insect larvae, and the high temperature to which they are accustomed in the hive. A good proportion of the sealed brood would probably survive. We should advise you to transfer your bees, either very early in the morning, or, better still perhaps, after the main work of the day is over. You need not fear annoyance from the bees who are straggling home, especially if you operate upon them at some little distance from the hives. Can any of our readers furnish our correspondent with the number of the *English Mechanic* in which there appear sketches of the various parts of the hive as promised by Mr. Abbott? Your experience of the honey season appears to be similar to that of most apiarians—little honey and few swarms, and these mostly very late.

TRANSFERRING HIVES OF BEES (*A Regular Subscriber*).—Nothing is easier than the removal of wooden hives by rail. Simply screw the hive firmly to the floorboard, nailing with tin tacks pieces of perforated zinc over the entrance way and over the hole or holes for supers at the top of the hive for ventilation. Turn the hive topsy-turvy, and let it travel so; cord it well, and if not too full of bees, and the weather not too hot, they will travel any distance. We should prefer October or November, when the population is reduced in number and the weather is cooler. If your straw hives have wooden rims they can be screwed in the same manner to the floorboard; if not, you must secure the hive to the board in such a manner with stout cord as to prevent all risk of its shifting, and treat otherwise as mentioned above. All the work should be done the evening before they travel.

FEEDING BEES (*B. G.*).—From your use of the words "captured" and "cap" we hardly know whether you mean to imply that you caught a swarm, or placed a cap or super on an already established stock. If the latter, you should remove the cap, and, if the combs are clean, wrap it up and put it by in a safe place till next summer, when it may be again given to the same or some other hive to be filled. But, whatever you meant to convey, the bees in your hive must be fed, being, as you say, very light; for which purpose you must boil 6 lbs. of loaf sugar and 4 lbs. of water by weight, for five minutes. When cold fill a pickle bottle, the some rather coarse muslin or net

over the mouth, and invert the bottle on a piece of perforated zinc placed over the hole in the top of the hive. If there is no suitable zinc you must cut one of about 3 inches in diameter, and fix on a piece of wood having a 2-inch hole to correspond, on which the bottle will stand securely. It must be well covered up to prevent the access of robber bees, and, if possible, the food should be supplied at night and the bottle removed in the morning, when, if the stock is pretty strong, all the food will have been taken down. This board, if large enough and properly clamped at the ends to prevent warping, will also be found available for working a super. Send five stamps to our office and order "Bee-keeping for the Many," in which you will find ample information on feeding, and on many other matters in connection with bee-management.

REMOVING SUPERS (*Bank Villa, Dewsbury*).—On our return home from our usual summer holiday we were distressed to find that your query of July 21st had been overlooked. Accept our sincere apology. We fear any remark of ours is too late to be of service, but we may say generally that, except on the moors, all supers of honey should be now removed, except such as have but little honey in them, which may be stowed away with advantage for another year after the bees have taken down the honey.

PRESERVING KIDNEY BEANS FOR WINTER USE (*The Gardener*).—We published the following receipt last year:—"Put a layer of dry salt, about half an inch thick, in the bottom of a well-glazed earthenware pan, on this a layer of beans about 1 inch thick, another layer of salt, then another layer of beans, and continue in the same order until the pan is full. Keep in a dry cool place. When wanted for use they must be taken out in layers."

REMARKS.

- 20th.—Morning fine, but cloudy day; very heavy rain for a few minutes about 8.40 P.M.
- 21st.—Fine morning and till noon; then cloudy, but fine from 4 P.M.
- 22nd.—Fine early, rain at 9.30 A.M.; fine at noon; sunshine and showers all day.
- 23rd.—Fine early, very thick at 8 A.M., fine by noon; lightning at 8.50 P.M.
- 24th.—Dull early, fine by 10 A.M.; cloudy by 4.30 P.M.; very dark at 5.30; very heavy rain at 6 P.M. for about eighteen minutes, measuring during that time 0.66 inch; thunderstorm commencing at 7.30, and continuing more or less till 2 A.M. on 25th, thunder at no time very loud or near. Storm commenced in the S.W., went round to N.W., and back to S.W. in the early morning of 25th.
- 25th.—Fine all the day.
- 26th.—Rather dull at 8 A.M., but fine soon after, and so continued all day. Weather very similar to preceding weeks.—G. J. SYMONS.

COVENT GARDEN MARKET.—AUGUST 27.

SUPPLIES not so large this week. Currants, Raspberries, and Gooseberries are nearly over, but heavy goods are plentiful, remaining at last quotations. Pears and Apples from the Continent, with various kinds of common Plums, find a good sale at auction just now, chiefly for the north.

From observations taken near London during forty-three years, the average day temperature of the week is 70.0°; and its night temperature 47.1°. The greatest heat was 91°, on the 7th, 1868; and the lowest cold 23°, on the 7th, 1856. The greatest fall of rain was 1.27 inch.

HOUSE SEWAGE A SAFE AND MOST VALUABLE FERTILISER.

Many letters have reached us asking so earnestly for our opinion "whether the use of house sewage is likely to produce disease either in man or animal partaking of the crop to which it is applied?" that we insert this answer to all our querists thus prominently.

One correspondent encloses the following extract from *Medical Notes and Queries*:—"Is all the food absorbed by plants digested and assimilated by them? We are afraid to dogmatise even where the facts appear incontrovertible, but we can have little doubt, if any, that in many cases plants, like men, take into their systems much more food than they can digest, and that foul juices may, therefore, exist unchanged within their vessels. A simple illustration will suffice to show this, and we will only refer to the well-known fact that early Rhubarb, unskilfully forced with horse droppings, will often taste strongly of the manure. In the case of pastures, who can doubt that plants so crowded together as the Grass plants are, must be weakly; that their digestion, probably, is so too; and that if their supply of food be not very carefully regulated for them, fluid matter, of whatever kind, that is brought in contact with their absorbing surfaces will be taken up in greater quantity than can be digested, and, consequently, that some of it will remain unassimilated and unchanged within the tissues of the plants? Positive observation, indeed, supports this view. Herr Lefeldt, a civil engineer appointed by the Prussian Government to report upon our sewage systems, found that, for some inches above the roots, the stems of sewage-irrigated grass were filled with unassimilated fecal matters; and that if the irrigation were continued till within two days of mowing, the cows would not eat the grass. Why should not sewage matter existing thus unchanged within the tissues of grass produce the same effect upon the animal that swallows it, as if it were taken directly, without the intervention of the plant? We can see no reason why there should be any difference; and the argument from the observation of Herr Lefeldt, therefore, appears to be a very simple and direct one. It may be stated as a syllogism thus: No one denies that sewage matter, unchanged, will cause typhoid fever; but sewage grass, under certain circumstances, contains sewage matter unchanged; therefore, clearly, sewage grass may, under certain circumstances, transmit the typhoid germs."

Now we assert without any reservation that neither Herr Lefeldt nor any other examinant of the subject ever found any fecal matter in the stem of any growing plant. If the plant was dead or dying, then by mere capillary attraction such matter might pass into the tubes of the stem. Whilst a plant is alive its roots are endowed with a selecting power, and they never absorb anything prejudicial to the plant's health. This was long since demonstrated by special experiment. M. Sausure found

"when various salts were dissolved at once in the same solutions, and plants made to vegetate in them, that different proportions of the salts were absorbed. The following table exhibits the result of these trials, supposing the original weight of each salt to have been 100. Each solution contains 1/50th part of its weight of each salt.

1	Sulphate of soda effloresced	11.7
	Muriate of soda	22.0
	Sulphate of soda effloresced	12.0
2	Muriate of potash	17.0
3	Acetate of lime	8.0
	Muriate of potash	33.0
	Nitrate of lime	4.5
4	Muriate of ammonia	16.5
	Acetate of lime	31.0
5	Sulphate of copper	34.0
	Nitrate of lime	17.0
6	Sulphate of copper	34.0
	Sulphate of soda	6.0
7	Muriate of soda	10.0
	Acetate of lime	0.0
8	Gum	26.0
	Sugar	34.0

"These experiments succeeded nearly equally with other plants, as the *Mentha piperita* and the Scotch Fir. When the roots were cut or removed, the plants absorbed all solutions indiscriminately."

Then that plants do not retain what is noxious, we have this decisive evidence:—

"The experiments of Macaire-Princep have shown that plants made to vegetate with their roots in a weak solution of acetate of lead (Goulard's extract), and then in rain water, yield to the latter all the salt of lead which they had previously absorbed. They return, therefore, to the soil all matters unnecessary to their existence. Again: when a plant, freely exposed to the atmosphere, rain, and sunshine, is sprinkled with a solution of nitrate of strontia, the salt is absorbed; but it is again separated by the roots, and removed further from them by every shower of rain which falls upon the soil; so that at last not a trace of it is to be found in the plant."—*Daubeny.*)

If we refer to the results of extensive practice we have the irresistible evidence of the hundreds of acres of grass produced during many years solely by the aid of house sewage on the Duke of Portland's land near Mansfield. No disease has that grass produced in the cattle that have consumed it. That house sewage put upon a garden near a residence is never offensive we can testify from our own long experience, and certainly the crops produced by its aid never caused typhoid fever, nor any other disease.

We have tried house-sewage as a manure to Potatoes, Peas, Beans, all the Cabbageworts, Asparagus, Rhubarb, Sea-kale, and Grass; and it has yielded us, of all of them, from a light soil resting on chalk, the best crops we have ever grown.

Our mode of applying sewage is to soak with it the ground previously to digging, and growing every crop in rows with wide intervals, to pour the sewage as we deem needful in gutters made with the hoe between the rows.

Mr. Cuthbert Johnson, of Waldronhurst, near Croydon,

employs it chiefly for irrigating grass, and he obtains by its employment four or five heavy mowings annually. This is from a light, sandy soil.

That sterling old gardener, the late Mr. Beaton, used it in the cultivation of his bulbs, and other flowers, with the utmost success; and until we applied it to Roses and Chrysanthemums they refused to excel on a chalky soil. Mr. Beaton wrote to us—"When a crop of anything is in rows, whether they be bedders or for the pot or table, liquid manure of any strength may be applied in the centre between the rows with less risk or danger than in any other way. I have often with my own hands poured down large quantities of the very strongest liquid manure between the rows of plants, one drop of which would be destruction to any one of them if it touched the leaves or roots; but filtering to the roots through a few inches of soil all harm is avoided, which goes to show that a fair porous surface of earth is the best and safest fixer of ammonia and all over-strong matter in the liquid. Every one of my own bulbs, from *Crocus* to *Hesperanthus*, gets it every spring from a place which one would shudder at the idea of, and I never lose a leaf. I quite agree with clarifying liquid manure for pot culture, and in the hands of those who do not know practically what a plant can digest, or what the strength of their liquid is. But to keep a bed or border in good heart for a whole season at the least possible expense, have no recourse to clarifying the goodness out of the stuff, but give it to the plants fresh from the stable, cowhouse, piggery, or where it may be got much stronger, and one good soaking of it will last the whole of that season; the spring is the right time to apply it. Then, in June, if a handful of mould from below the surface is as good as a smelling bottle, you may depend upon a good show of Roses, and most bedding plants, if the beds wanted any assistance that way. The old florists who placed 4 or 5 inches thick of strong dung at the very bottom of their beds, and 2 feet below their plants, were much wiser in their generation than those of us who supply rotten dung on or near the surface. Mr. Rivers has been recommending, for a long time, one or two thorough good soakings of the richest liquid manure to the Rose beds in the winter; and if Roses are ever to come out healthy on a thin, poor, sandy soil, that is just what will do it. When flower-beds and borders get exhausted by cropping, this strong liquid is very much better for them than rotten dung."

As to forced Rhubarb having a flavour of horseradish, we know both in that and in forced Sea-kale that it is occasioned by the gases emitted by the fermenting dung. The reek extends no further than the epidermis, and usually may be removed by washing, and always by peeling off the thinnest film of the epidermis.

THE CALCEOLARIA DISEASE.

Once more there are complaints about the disease in the bedding Calceolaria; and although there is reason to believe it is not so prevalent or so severe in its effects as in some previous seasons, yet it appears to be as puzzling as ever, for both the origin of the disease and a remedy have not, so far as I know, been discovered. The qualifications of the Calceolaria for bedding purposes stand so high, that gardeners may safely be trusted to try any experiment or make any effort that is likely to stamp out the disease entirely, or even to palliate its effects; but as each successive season comes round it makes its appearance, and is more or less destructive. At the same time the disease is partial in its attacks, for while some localities almost escape for one season, the succeeding season is likely to bring the disease in its severest form. This difference and partiality of attack lead one to conclude that the disease arises from atmospheric influences. Again, taking into account the time of year at which the disease makes its appearance (which is generally the latter part of July or the beginning of August, when the plants are to some extent exhausted by their first blooming period, which, by-the-by, is generally the best, and at which time the plants are less able to bear any particular pressure upon their circulating powers), I am led to think that the hot sun playing on the plants from morning till night, and the very rapid evaporation consequently going on without any counterbalancing treatment, so checks the growth and favours the ripening of the wood, that the plants cannot recover their former vigour, and consequently die.

Such is the opinion which I formed years ago, and having always had a fancy for the cultivation of the Calceolaria, I shaped out a course of treatment which I thought then, and

still think, is not an unreasonable one. That it is a safe one I have proved from experience, because since I practised it I have seldom been troubled with the plants dying-off by disease. I also think that in the treatment of the Calceolaria the soil in which it is grown should not go unnoticed, for I am of opinion that some sorts of soil predispose a plant to disease by throwing it into a sickly state through obnoxious ingredients, or from the want of fertility to enable a plant to maintain a vigorous constitution against the attacks of disease. In the case of the Calceolaria I consider a light sandy soil would favour my last opinion, so also would a gravelly one, and a poor kind of loamy soil, if shallow, would do the same. In either of these compositions the Calceolaria flowers but once, and that flowering is soon over, without the plant making the necessary growth for a continuance of blooming. What we call a cool showery summer might alter things a little, but even then they do not come up to the standard of excellence as sometimes witnessed, but oftener wished for than produced in this particular flower.

As a rule, Calceolarias grow well at first, and again when the rains and cool nights of autumn come on; but to carry them successfully through the hottest part of the year, and keep them continually in flower, is where the skill of the cultivator should be directed. To do this does not, in my opinion, depend upon the treatment at the time, for nothing seems to recover them then. It must be a pre-arranged plan, mostly as regards the treatment of the plants in the spring and the soil employed.

I prefer to take the cuttings as late as possible in the autumn consistent with the state of the weather, and root them in poor soil not much if at all before Christmas. After that I keep them as cool as they will bear night and day. At the beginning of February every one will need the centre shoot plucked-out, and when they show side shoots plant them out in some temporarily-prepared place, but still in poor soil; here they may stand, with attention, until wanted for the beds. My aim is to keep the plants as hardy as possible, and plant them in a soil only rich enough to keep them in health and produce growth enough that, by stopping, &c., a foundation may be laid for a good plant. I think it is a mistake to grow the plants so vigorously in their winter quarters as some do; it is in the flower beds where this vigour is required, and this must be supported by a suitable soil, which I consider to be a sound turfy loam, not too retentive or binding, but a maiden loam that possesses some richness. This should be chopped up roughly; then add to it about one-third of well-rotted hot-bed manure, or, what is better, one-fourth of decomposed night soil which has had a good sprinkling of lime. Lay up these materials with the loam for a twelvemonth, and turn over the compost occasionally. In spring take out the old soil, place the compost in the bed to the depth of 18 inches or more, and during the summer water the plants copiously—at least three times a-week. If Calceolarias do not thrive in this soil I shall be surprised indeed. I have tried this soil on a large as well as small scale; and at Hatfield, where I used it for several large beds, nothing could look more cheerful than for a favourite plant to be in perfection both of bloom and foliage, and entirely free from disease, as was witnessed and remarked upon by those who were competent to judge of their merits. Previously, there was considerable difficulty occasioned by the disease. This treatment has given me so much satisfaction for the past seven or eight years that I shall not only continue the practice, but would advise those who have not adopted it to give it a trial.—THOMAS RECORD.

PEACHES AND NECTARINES.

THE spring for these fruits out of doors was the worst I ever remember. Under glass, in my little viney—the Vines being cut back one-third of the length of the rafter to let in light to the Peaches and Nectarines planted-out on the brick flue at the back, and trained to wires—the crops are superb, the sorts being Royal George, Bellegarde, Albatross (one of the largest and best-formed of all Peaches here), Golden Eagle, and three trees of the Rough Roman Nectarine, *alias* Newington, which, when ripened, is the richest of all the Nectarines. Out of doors, except in favourable seasons and warm gardens, you can rarely ripen it. It is a clingstone.

My crop under glass of Peaches was 79, and of Nectarines 45. Out of doors, of Peaches 171, and Nectarines 60. This is a poor return for so many trees, almost all small, 120 in and out of doors, some few of them being maidens. A

beggar once told me, when I said I would give him nothing, that there was "no taste in that article, and that I could not give him less." I have had "a taste," and am satisfied. The trees of all kinds are in beautiful condition, and are fast forming their triple buds for next year.

There is one new Peach here which well deserves praise. It is Mr. Bivers's Early Louise. It is a small tree, in its second year, in an exposed east wall. Though hardly any tree on that wall sets its fruit, except the Royal George, Early Louise set its blossoms well, and I gathered the crop, averaging 8 inches, ripe on August 1st. On my south wall it would have been ripe July 12th to 14th. The fruit is juicy and delicious. The tree is full of fruit-buds for next year. I shall put a tree of it on my south wall in the autumn. I can safely recommend it. Early Rivers and Early Beatrice in better situations lost their flowers, so that I cannot speak of them. All three sorts appear to be hardy and good growers. The Royal George indoors and out, on east, west, and south aspects, beats all here. Early Alfred, Barrington, Princess of Wales, and Nectarine Peach are next best, and well cropped for the year. Emmer-ton's White Nectarine out of doors, and Rough Roman under glass, beat all the others. The next best crop is Rivers's White Nectarine, derived from the former. Both the White Nectarines are delicious and handsome when well ripened.

A great many of my trees, out of doors, on all aspects, either did not set their fruit, or it dropped off from the severity of the weather and the exposure of all my walls. If the weather is not hot enough to bring out bees, it is not hot enough to ripen the pollen, without which the fruit cannot set. If the weather is cold, and the pollen on the stamen is pasty, fertilisation cannot take place. I believe bees are great helpers. I found three in my viney in the spring, and I locked them in; doubtless, they helped to set a capital crop of fruit. It is said you cannot have these fruits under Vines on the back wall. It is quite untrue. Cut back the Vines one-third of the length of the rafter, and you will get a capital crop of Peaches and Nectarines, and just as many Grapes as if you allowed the Vines to go to the top of the rafter; because, when shortened, they drop close to the lower wall-plate.

Fruit under glass never colours so well as out of doors. Noblesse under glass would be a delicate creamy green, out of doors it is dappled like a Pomeranian coach dog, and very handsome. It is the richest of all Peaches. I disbud scarcely at all, and never shorten anything till the tree is in full foliage. I then shorten some twigs to the first pair of full-sized leaves for spurs, and others longer. People pull out the lungs of the tree, and then are surprised that the tree degenerates. I have just finished cutting off a portion of each leaf, except where fruit is, to let in light, air, and heat to the walls for the maturation of the wood and to prevent excessive wood growth. Visitors always admire the clean and beautiful foliage. Take care of the foliage and the roots, and the rest of the tree will take care of itself.—W. F. RADCLIFFE.

AUTUMN-SOWN ANNUALS.

I no more think of omitting sowing a crop of these in autumn than crops of Cabbage, Cauliflower, or Lettuce. Annuals are, moreover, as certain in their issues as are the vegetable sowings above named, and fill a gap in their way as great. Considering, too, the outlay and trouble involved, the relative returns are certainly as great as any display that can be produced in the garden. Every year I can see the admiration these simple flowers call forth and the pleasure they give, and this is why I never forget to sow, and seldom forget to issue a reminder to others who care to have them, to sow them also. As "welcome as flowers in May," is an old and remarkably expressive adage, for flowers are, in fact, at that season especially longed for—and why? because they are bright and cheering messengers, telling us that another morn of life is born, sparklings of spring, and harbingers of summer. Simple spring flowers must be estimated as what they are, and by their own merits, or they have not due justice. A verdict—and it is too common—that "they lack the glowing richness of summer and autumn masses, and we put them out of court," is not a fair one. I go further and say it is not an intelligent one. What should we think of a man directed to admire a glorious sunset turning away with, "Oh! I don't care for that, it will be ten times brighter to-morrow?" I can understand annuals not being grown because a particular system of gardening does not require their aid, or that they may bloom at a particular time when a garden is vacated by the effect when

it is made enjoyable, but not because they are destitute of beauty, or not so bright as brighter things.

I know annuals have charms to many, and, used in conjunction with bulbs and spring perennials, a garden can be made as fully attractive in April, May, and June as at any other period of the year. But gardens worked on the ordinary massing system, it is only practical to say, are sometimes interfered with by a prolongation of spring bloom in the beds, and the holding-back of thousands of plants, involving much labour in attention to their wants, in pots and stores. To have the crop of flowers off by the middle or end of May, only a limited number of plants, besides bulbs, are available. In addition to Hepaticas, Daisies, early Pansies, and the Primrose family, the following may be used:—Silenes, especially pendula, to be sown at once; Forget-me-nots should be now ready to prick-out; Collinsia verna, better sown in August, but will do now; Veronica glauca, sow now; Virginian Stocks, sow second week in September, or even February; Euphorbia californica, and a chance of Nemophila and Limnanthes, sow any time before the 15th inst. These are all early and give white, blue, pink, yellow, and orange. August-sown plants of the pretty Saponaria all flower early, but are not always past their best until May is out. For beds intended for more tender subjects, as sub-tropical plants, a prolongation of bloom in autumn-sown annuals is an advantage. They are the very plants to use freely. To some or all the foregoing, the Clarkias, Collinsias, Campanulas, especially pentagonia and Venus's Looking-glass, Visceraria, Candytufts, Platystemon, Larkspurs, and a few others may be sown any time from the 5th to the 20th inst., except Collinsias (excluding verna), which are better not sown until quite the end of the month, or their upright, rapid, succulent growth may render them a prey to frost-damages.

In mixed beds or borders autumn-sown annuals always show to advantage, and give an air of cheerfulness to a place at a particular season in a way which nothing else can do. Whatever charms may belong to hardy annuals, they can never be fully brought out except by autumn sowing and spring flowering.

Sown in spring, and, as is often the case, neglected, they are little better than rubbish, but sown now and tended they are really gay and attractive. Sown in autumn the plants are stronger, their flowers finer, and duration longer, than when sown in spring. In fact, their period of flowering is long enough.

These simple flowers have a beauty of their own, and are to most people pleasing. There is nothing to go into raptures about; they give a quiet soothing pleasure. I know a rectory where a batch of blue Nemophila has for years taken care of itself. Every morning of every spring, when in flower, it was visited by the rector, who derived more pleasure by this simple sheet of blue than any other flower bed in his garden. In their management a few points must be attended to. As to site, let it be as far as possible away from the lurking places of slugs and snails, as old walls, spreading herbaceous plants, &c. As to soil, do not have it rich or dig it, but run the hoe through, lightening it to the depth of an inch. That is all that is necessary, and better than doing more. As to sowing, let it be done in drills a foot apart, regulating depth according to size of seed—Nemophila, for instance, being covered half an inch, Venus's Looking-glass merely dusted over. If dry, soak the drills thoroughly before sowing; it is of no use watering after. Further attention must be given—first to thinning, letting each plant stand separately and stool naturally. This is important, and makes all the difference between crop and no crop; second, running the hoe through frequently, and by every means keeping slugs at bay; third, in severe frost and no snow, covering lightly over with Asparagus tops or Fern, but snow is the best protector. After all, however, thinning early and sufficiently is the best safeguard against frost. Attention to these hints will result in a supply to be lifted and transferred to the beds on the first fine weather in spring. If an early-and-soon-over display is wanted, plant as thickly as possible, covering the ground at once; but if a lengthened bloom is desired, plant thinner in proportion. Finally, if the worst come that can come, and a hyperborean winter kill all (which is seldom), the money loss will be trifling and the land loss nothing, and disappointment may merge into a determination to try again. I have not had one total loss in fifteen years.—J. WRIGHT.

GARDEN NETTING.—I am glad attention is being called to the question of selling netting by what can scarcely be called any-

thing but an unfair mode of measurement. If I want 25 yards of 4-yard-wide net it is measured for length by pulling it tightly in the direction of its length, and for width by pulling it tightly in the direction of its width. Measure a piece of 1-inch-mesh netting, 4 yards by 1 yard; the 4 yards drawn tight become 8 yards, and the one yard stretches to two when also drawn tight. Open the net and lay it evenly—*i.e.*, the diameters each way of a single mesh being alike—*viz.*, an inch, and the superficial loss is seen at once. Is the method of selling, or rather of measuring, fair? or is it after all only the "reputed" quart and the "imperial" quart over again?—A. R.

NOTES ON LILIES.—No. 1.

LILIUM LONGIFLORUM.

You asked me for some photographs of our Lilies, and for some gossip about them. I will begin with *Lilium longiflorum*, the pot with twenty-two blooms and two buds; height 3 feet 9 inches, width 3 feet 8 inches. The bulbs were bought at auction as *L. eximium*, which they are not. Our knowledge of *L. eximium* is rather uncertain. I understand that this was found by Siebold among *L. longiflorum*, and have always understood it to be rather dwarf-growing, with the mouths of the tubes expanding widely, and I have a Lily with these characteristics. I am now told that *L. eximium* of Siebold has

Lilium longiflorum.

according to M. Duchartre, a very long tube, and my friend, the great authority, Mr. Leichlin, confirms this, and states that it has the character of what he formerly named *L. longiflorum* Wilsoni. The pot is *L. longiflorum*, the size and height being due to the favourable conditions of growth in an orchard house, with abundant watering.

It is a very beautiful Lily, though inferior in height and size of flowers and length of their tubes to *L. longiflorum* Wilsoni. I often wonder it is not more generally grown as a conservatory plant. Here it has been constantly said by visitors of good taste, "Your Lilies are all beautiful," but none are more beautiful than this, with its pure white tubes contrasting with the fine green leaves. With us it grows well in the borders, but owing to its being a very early Lily it, unless sheltered

and retarded by dwarf shrubs, is often checked and injured by early frosts. With us it grows best in sheltered corners with a northern aspect.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath.*

STRAWBERRY CULTURE AND MERITS.

AFTER so many have stated their Strawberry experience of the year, I am afraid my chance of saying anything fresh on the subject is very small; however, I cast in my mite, and I shall try and make my remarks as plain and practical as possible.

The crop of Strawberries this year has generally been very abundant, but owing to the dull and sunless weather we had the fruit did not acquire its proper flavour, and the wet caused the decay of great quantities; a small black beetle also made sad havoc amongst some of our fruit, by eating large holes in the berries. Some people fancy the cause to be slugs, but I believe the beetle is the offender, as we have caught large numbers when gathering the fruit, and the beetles were right in the centre of it. Notwithstanding all these losses we have been able to gather from 150 lbs. to 200 lbs. daily when our main crops were at their best.

Early Prolific (Dr. Roden's) is my best early variety; it will take the place of Black Prince with me, as it is only a few days later, and a much superior fruit. Next is Marguerite, a most abundant bearer of very showy fruit of immense size, but that is all it has to recommend it, as the flavour is very deficient, and the fruit when ripe will scarcely bear to be touched, it is so soft. Keens' Seedling succeeds these two, but it does not bear so well here as I should like; a great many of the plants turn out barren, notwithstanding their being carefully selected before planting. Amongst my main-crop Strawberries I must place President at the head of the list; it is a sure and most abundant cropper of very large fine fruit. Sir Charles Napier has this year done badly with me; there was a very abundant crop, but owing to the wet great quantities of the fruit decayed; still it is a good variety, a great cropper of beautiful shining-looking fruit, with a nice sharp flavour, which some prefer. Next in order comes British Queen and Dr. Hogg, the best-flavoured two Strawberries I know, but our soil is too light for British Queen. Dr. Hogg is not a great cropper with me, but the fruit is magnificent, and the flavour everything that could be desired. As succession crops for forcing they both do remarkably well. Dr. Hogg in a cool Peach house with me this year was the connecting link between in-door and out-door fruit. Duke of Edinburgh has done exceedingly well with me this year, I intend cultivating it largely; it is a superior variety as regards size, colour, and flavour. My variety of Prince of Wales I do not like at all; it is a strong grower, and bears abundantly, but it is very deficient in flavour, and the fruit is small. It is a little later than the above-named varieties, for which reason I grow a few. Carolina Superba and La Constante are two good varieties, the former is not a great cropper but the flavour is superb; in La Constante we have both qualities up to perfection, and it is likewise a beautiful-looking fruit. Goliath is a variety I have here resembling La Constante in habit, but more robust; fruit on short footstalks, and entirely hidden by the foliage; a most abundant cropper, and always sure, but it is rather deficient in flavour, and when fully ripe is rather soft in wet seasons. I also grow Rifleman, Empress Eugénie, and Cockcomb; with regard to the latter two they are good croppers, but both have very ugly-shaped fruit, and they do not colour well. I also grow the Alpine variety, which I am now sending in for dessert; it is quite equal to Black Prince as regards size, and if the flavour is not first-class, still it makes a nice variety on the dessert-table, and is relished, too, as the dishes are always brought out early.

My method of culture I stated in your Journal last year, but on reading some of your correspondents' articles I see there is a great diversity of opinion as to the length of time the beds will continue bearing satisfactorily. Some say two years; others say ten or more years. For my part I consider it greatly depends on the mode of culture adopted. If they are cultivated in beds, and the runners allowed to root and remain on the bed, I consider that they are past their best after the third year; but, on the other hand, if the ground is properly prepared, and the plants kept as individual plants by having their runners all trimmed away when they have done bearing, and in the autumn an annual top-dressing of well-decomposed manure is applied, I have no hesitation in saying that they will continue bearing satisfactorily for a much longer period.

I was very pleased to see in a former number of your Journal that Dr. Roden was bringing his new seedling Strawberries to the front. I can fully corroborate his remarks respecting them, as I have had an opportunity of seeing them growing, and I feel quite satisfied that they will be valuable additions to our varieties of Strawberries. I have not the least hesitation in saying that when they become public they will cause a good many of our old varieties to be swept out of the garden. Dr. Roden is a gentleman who has devoted a great deal of time, attention, and study, to cultivating and improving the Strawberry, and it is very gratifying to think that he is again rewarded with some valuable seedlings.—J. ANDERSON, *The Gardens, Hill Grove, Kilderminster.*

MR. LUCKHURST seems to me somewhat to beg the question, when he thinks his standard of quality with regard to Strawberries must be higher than mine. I am not accustomed to put a low standard of perfection with regard to anything, either fruit, flowers, or otherwise; and as the Strawberries I alluded to have been seen and tasted by many persons well qualified to give an opinion, and I have never heard but one opinion expressed with regard to them, I still adhere to what I before said, that Strawberry beds may, under proper cultivation, be made to bear fruit of high quality and in great quantity for several years in succession. I took fruit from these beds two years ago to Dr. Hogg, when I happened to be going up to London to him on a visit, and he pronounced them to be as fine as any he had seen exhibited at the London fruit shows, and I have seen no deterioration in these same beds, either in quantity or quality, these last two seasons. So much for the question as to standard of excellence.

When Strawberry beds become old and exhausted, it is because the runners are allowed to grow, and the beds are matted together so that the crowns are injured.

Strawberries on beds are not produced from the runners of the previous year, but from the crowns, and every inducement should be made for the crowns to make strong offsets, not runners. A strong crop of fresh leaves caused by hoeing and manuring among Strawberries now, will not in my opinion improve the fruiting of the beds next year; in fact, as a general rule, the crop of fruit is in almost inverse proportion to the leaves, especially if there is much growth of foliage either late in autumn or very early in spring, so that, although Mr. Luckhurst's argument seems to be a strong one, I am obliged to differ in *toto* from his conclusions. If Mr. Luckhurst's plan be followed, of course old beds will wear out. All I am wishing to argue for is, that under other treatment the growth of the crowns is renewed without a crop of runners, and that manure is applied to the plants after the crowns have matured, and the roots appropriate the manure to feed the flower and fruit, and not the foliage. We should succeed very indifferently with most fruits if our attention were turned to supply vigorous leaves and wood-growth, though, as in everything else, the happy mean is the right one. I prefer the application of mulching to protect my plants during the winter, and to continue the root action, and not depend upon leaves for protection, which in our north country are not to be depended upon; and, as I have before said, I do not care how few leaves I see upon my plants when the season for spring growth commences.

Of course, in venturing to dispute the recognised and stereotyped treatment of Strawberries, I lay myself open to the remarks which Mr. Luckhurst makes, but I should not have written the article Mr. Luckhurst alludes to had I not equally based my conclusions on practical experience. I do not wish, however, to be misunderstood. I have no desire to find fault with the recognised system of renewing Strawberry beds; I only wish to assert that good fruit can be grown with the other system, and this was the reason why I ventured to dispute Mr. Luckhurst's assertion, that old beds always produced fruit of a paltry description.—C. P. PEACH.

THE columns of the Journal have lately been unusually rich in Strawberry lore, and the varied points touched on by different growers one would fancy would enable anyone having a garden to enjoy a supply of this estimable fruit. Mr. Luckhurst can evidently make Strawberries grow anywhere, and with such soil as he works on I am not surprised at his advocacy of treating them as biennials, and I feel quite sure that on his particular kind of soil he can so obtain more fruit than by any other means. Mr. Peach has evidently more "body" in his soil to hold them on as perennials; so have I,

if I never dig and top-dress continually; yet, with early and good plants and a good season, I can get better fruit off plants a year old than any other.

But we must take seasons into account, and act accordingly. For instance, the rainfall in the garden under my charge for the months of June, July, and up to August 17th is only 3.40 inches, an unclouded sun prevailing nearly the whole time. This, and a limestone base many feet in thickness, keep me from digging up my yearlings. So, also, I must let alone some two-year-olds, and by thinning the crowns slightly, and always keeping the surface of the ground covered, I expect a useful crop. Thus do seasons upset pre-arranged plans. The weather cannot be ignored, and a mere rule-of-thumb practice can never be relied on in spite of it. To make the best use of the best advice, it must be taken subject to weather contingencies and local expediency. Scores of people cannot if they would turn a dry season into a wet one by the watering-can, and yearling plants cannot be fine without plenty of moisture and support to carry them to maturity without interruption. Therefore I see no inconsistency, but the reverse, in advising the digging-up plants one season and letting them remain another if weather-changes demand it. They demand it now, and I shall not grub up hastily, and advise others similarly circumstanced to hesitate also; and the warning may be useful, considering the advice—excellent at the time and in itself—that has been given by different growers.

I note what has been said against Vicomtesse Héricart de Thury. I recommend it because I find it early and free-bearing, and not for its high flavour, yet its sparkling sub-acidity is enjoyed by many palates. I know something recommends it by the many applications I have for "runners." Anything distinctly early or decidedly late in Strawberries is always a desideratum, and if we can only get the fruit there will be no great fight as to nice points in flavour. We cannot net them up like Gooseberries and Currants, and prolong the season.

I am glad to see what Mr. Douglas says; kindly differences are always instructive. He wonders, and with, no doubt, good reason, that anyone should grow Elton as a late kind, while Frogmore Late Fine is so much superior. I am not quite sure whether I have had the true Frogmore, but, at any rate, such as I had would hardly grow or fruit at all. The plants were not from a sturdy stock, and I am fully sure that growing Strawberries of unhealthy parentage is terribly uphill-work. As to Dr. Roden, I can say no more than that he and the artist make one's mouth water.—J. WAGNER.

POTATOES AS THEY ARE.—No. 2.

NORTHAMPTONSHIRE.—In answer to your inquiry respecting Potatoes, I am very pleased to give you a favourable report. I have about thirty varieties planted, and have found very few diseased. My plan is, whenever I see the "fatal" spots, which generally come in small patches, to cut off the tops immediately. I hold that small sound Potatoes are preferable to large diseased ones. The yield this season is astonishing—fine, clean, and large tubers, and many of them of first-rate quality. Among the best is old Lapstone Kidney, an enormous cropper in well-worked land; Bresee's King of the Earlies, Excelsior Kidney, Bresee's Climax, are also of first-rate quality. We have already lifted some tons of the earlier varieties, such as Veitch's Royal Ashleaf and Hogg's Coldstream; the latter, when true, is all that can be wished, but it requires careful selection yearly. Early Rose is also capital this season, but not of the quality of those mentioned, still when they have to be supplied in large quantities it is not to be grumbled at. Primer, one sent here by my friend, Mr. Johnson, Savernake, is a first-class one, being of good even size, a prodigious cropper, and of fine quality. Late varieties I have not yet tried, but will send word about them in due time.—R. GILBERT, *Burghley Kitchen Gardens, Stamford.*

CHATSWORTH, DERBYSHIRE.—The Potato crop is magnificent in my immediate neighbourhood, the finest crop that has been seen since 1845; but I regret to say the continual wet of the past fortnight has had the effect of bringing on the disease slightly, and I fear it will get worse if the weather do not take up at once. The rains have been accompanied by thunder generally.—THOMAS SPEED, *The Gardens, Chatsworth.*

KIRKCALDY, FIFE—The Potato disease is certainly showing itself; here and there patches of spotted leaves are beginning to appear, but no word of disease at present. The crop, is very heavy, and of excellent quality.—PETER RISTOUL, *Raith Gardens.*

BANFFSHIRE, SCOTLAND.—The disease, I am sorry to state, has made its appearance where the crop is much shaded or growing in cold, stiff, wet land; but where growing exposed,

and the ground anything like dry, there are little or no signs of disease. If it keep off we are likely to have an abundant crop, both large and clean.—GEORGE MILNE, *The Gardens, Cullen House*.

STAPLEHURST, KENT.—As this is not a Potato-growing district I can only speak of the small quantities which everyone having a plot of ground invariably grows. The crop is generally spoken of favourably; the disease which manifested itself early in August in many places was restricted to the haulm, with only a solitary tuber here and there affected, and the fine weather we have had since then has, on the whole, checked it. The crop seems to be ripening off in tolerable condition; it is not heavy, but good in quality, and we trust will turn out well hereafter. I hear it stated that the much-abused American Rose promises to be tolerably good in quality this season, a matter not to be wondered at when all are better than usual.—J. ROSSON, *Linton*.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 3RD.

DAHLIAS, Asters, and Liliums were the subjects specially invited on this occasion, but the show of all three was of the most limited description; indeed, about 100 feet of staging was all that could be filled. The Dahlias from Mr. Turner, and the Lancifolium Lilies from Mr. Baines were superlative, but the other exhibits did not rise above mediocrity; indeed, than some of the Dahlias and Asters we never saw worse exhibited. In one kind, as shown by Mr. Turner and another exhibitor, there was a difference of diameter of 2 inches, and a corresponding difference in build.

Of Dahlias, three stands of twenty-four were shown. Mr. Turner was first with splendid massive blooms of Rev. J. B. Camm, Monarch, Arbitrator, Mr. Dix, Mrs. Saunders, Crimson King, Annie Neville, Egyptian Prince, Princess, Alexander Cramond, H. G. Quilter, Duke of Edinburgh, Flag of Truce, Toisson d'Or, Charlotte Doring, Incomparable, John Standish, Victory, Lady Gladys Herbert, Julia Wyatt, W. Keynes, John Neville Keynes, Ovid, and Prince Arthur. Second came Mr. W. Seale, Vine Nurseries, Sevenoaks, who had Charles Backhouse and Lord Palmerston, scarlet, very brilliant, and very good specimens of Peri, Hero of York, James Cocker, and others. Mr. Aldons, Gloucester Road, South Kensington, also exhibited. In Class 2, for twelve blooms, the best came from Mr. Burpitt, gardener to R. P. Taylor, Esq., Loughborough Road, Brixton. The second and third prizes were awarded to Mr. Beach, gardener to R. C. Petley, Esq., Riverhead, near Sevenoaks, and Mr. Gaines, Hampton Wick; the blooms from the last were very poor.

Of Asters, in the nurserymen's class for twenty-four not quilled there were none; in the open class for twelve Mr. E. Rowe, The Rookery, Rochampton, had the best; the remaining prizes going to Mr. George, Putney Heath, and Mr. E. Smith, gardener to T. D. Galpin, Esq., Bristol House, Putney Heath. Mr. Porter, gardener to Mrs. Benham, also sent a creditable collection. In the amateurs' class for twelve, not quilled, Mr. R. Anderson, 21, Blythe Street, Bethnal Green, was a good first, Mr. Rowe second, and Mr. George third.

For the best six Asters, not quilled, in 8-inch pots, the first prize was awarded to Mr. Smith, gardener to T. D. Galpin, Esq. These were fairly bloomed. Mr. Rowe was second, Mr. George third.

Messrs. Barr & Sugden offered prizes for trays of Asters, twenty-four blooms, not less than eight varieties, respectively of Pæony-flowered incurved, Victoria reflexed, and Pompon, or small-flowered. For Pæony-flowered Mr. Anderson had the prize, for Victoria Mr. Gaines, and for Pompons the same exhibitor was also successful with flowers averaging 1½ inch in diameter; while an extra prize was given to Mr. Anderson for a very good stand of quilled.

Although prizes were offered for Verbenas and cut Roses, no one came forward to claim them. For six pots of Lilium lancifolium (speciosum) Mr. Baines, gardener to H. Micholls, Esq., was first with splendidly bloomed plants measuring from 5 to 6 feet from the ground, and covered with innumerable blooms and buds. The varieties were rubrum, very free-flowering, album, and punctatum.

FRUIT COMMITTEE.—A. Smee, Esq., F.R.S., in the chair. A handsome Queen Pine Apple of 6½ lbs. weight was sent by Mr. James Harris, gardener to Mrs. S. H. Vivian, The Gardens, Singleton, Swansea; it was grown in a small pot from a sucker in sixteen months. A cultural commendation was awarded. A seedling Peach was sent by Mr. Powell, of the Royal Gardens, Frogmore, named *The Lady*, which was not thought any improvement on existing sorts. A seedling Plum was sent by Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, named *Welford Rose-drop*. The fruit is large, and resembles in flavour the Orleans, but was not thought by the Committee to be an acquisition. A Melon, named *Scarlet Perfection*, was

sent by Mr. J. Meakes, gardener to R. Fowler, Esq., Petersham, Surrey, but the flavour was very inferior.

A collection of Plums was exhibited by Mr. W. Earley, Valentines Gardens, Ilford, with the view of showing the relative time of ripening of twenty varieties. Mr. Earley also sent a bunch of Black Hamburg Grapes from a Vine said to be the parent of that at Hampton Court. The Vine was planted more than a hundred years ago.

A splendid dish of Jefferson Plum was sent by Mr. Dancer. The flavour was remarkably good, and a vote of thanks was voted to Mr. Dancer. Three seedling Nectarines were sent by Mr. J. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, which were thought highly promising by the Committee, and were asked to be exhibited again next year. A seedling Plum resembling Jefferson, named *Gordon Castle*, was sent by Messrs. J. & C. Lee, Hammersmith, but not so good as that fine variety.

Messrs. Monro & Wilkinson, Potter's Bar, Herts, sent six specimens of a very fine smooth Cucumber named *Duke of Edinburgh*. It has a remarkably short neck, and the fruit is of a very serviceable size—15 inches in length. A first-class certificate was awarded. A white-spined variety of Cucumber was also sent Mr. J. Meakes, gardener to R. Fowler, Esq., Petersham, but was not considered to be distinct by the Committee.

FLORAL COMMITTEE.—W. B. Kellock, Esq., in the chair. Messrs. Veitch & Sons, Chelsea, had first-class certificates for three splendid Begonias, two of which were stated to have been lifted from the open ground. All of them had large and splendid scarlet flowers differing in their depth of colour from *Vesuvius*, orange scarlet, to *Acme* and *Stella*, deep scarlet; the last-named, however, may not be, perhaps, so hardy as the others, as it was not said to be so grown. A first-class certificate was also awarded to the same firm for *Vanda Bensoni*, a Rangoon Orchid, forming a very fine specimen, with brownish dotted sepals and petals, and a pretty pale lilac lip. Mr. Burt, Shoreham Place, Sevenoaks, had a cultural certificate for a very fine specimen of *Saccolabium* with six racemes 16 inches long.

Dahlias were numerous shown by Mr. Turner, Slough, Mr. Wheeler, of Warminster, and others. The first-named had a first-class certificate for *Ovid*, rich rosy purple, one of the finest Dahlias ever seen. Mr. Keynes, Salisbury, had a like award for *Julia Davis*, yellow, also a cultural commendation for a stand of twenty-four. Mr. Harris, Orpington, had likewise a first-class certificate for Mrs. Harris, a very fine-formed and pretty flower, ivory tipped with pale purplish violet. Mr. Rawlings, Romford, had also a first-class certificate for *Miss Dennis*. Mr. Eckford, gardener to the Earl of Radnor, Coleshill, likewise sent a collection of Dahlias, and some promising *Verbenas* and *Geraniums*. From Mr. Douglas came a spike of a sweet-scented *Aërides*, name not determined. We might have extended our remarks on the Dahlias and other subjects exhibited, but for the extreme difficulty of ascertaining what their names were and by whom exhibited. It would convey but little information to our readers to state that *61 Dahlia* was a highly meritorious variety, unless we could also state the name it was to go by and by whom it was exhibited; and though names are, or may be, put later in the day than we are compelled to take our notes, it is certainly not till long after the Committee has ceased to sit. Several exhibitors practically do away, to a certain extent, with the difficulty by attaching their names to their productions. Such we believe is the confidence felt in the fairness of the decisions of the Floral Committee, that such a precaution as the numbering of the plants submitted to it seems wholly unnecessary.

RAISIN-MAKING IN CALIFORNIA.

Any industrious person who has the right kind of Grapes can make raisins; and raisin-making, which eighteen months ago had still a very uncertain future in this State, may now safely be called one of the established and most promising industries here. Last year I ate excellent raisins in Los Angeles, and tolerable ones in Visalia; but they sell very commonly in the shops what they call "dried grapes," which are not raisins at all, but damp, sticky, disagreeable things, not good even in puddings. This year, however, I have seen in several places good native raisins; and the head of the largest fruit-importing house in San Francisco told me, the other day, that one raisin-maker last fall sold the whole of his crop there at \$2 per box of 25 lbs., Malagas of the same quality bringing at the same time but \$2 37½. There is a market for all well-made raisins that can be produced in the State, he said, and they are preferred to the foreign product. At Folsom, Mr. Bugby told me he had made, last year, 1700 boxes of raisins, and that he was satisfied with the pecuniary return; and I judge from the testimony of different persons that at 7 cents per lb. raisins will pay the farmer very well. The Malaga and the White Muscat are the Grapes which appear here to make the best raisins.

For making raisins they wait until the Grape is fully ripe, and then carefully cut off the bunches, and lay them either on a hard clay floor, formed in the open air, or on brown paper laid between the Vine rows. They do not trim out poor Grapes from the bunches, because, as they assert, there are none; but I suspect this will have to be done for the very finest raisins, such as would tempt a reluctant buyer. The bunches require from eighteen to twenty-four days of exposure in the sun to be cured. During that time they are gently turned from time to time, and such as are earliest cured are at once removed to a raisin house. This is fitted with shelves, on which the raisins are laid about a foot thick, and here they are allowed to sweat a little. If they sweat too much, the sugar oozes on the outside, and this deteriorates the quality of the raisin. It is an object to keep the bloom on the berries. They are kept in the raisin house, I believe, five or six weeks, when they are dry enough to box.—(*New York Tribune*.)

PHOTOGRAPHS OF LEAVES.

ONE very simple process is this: At any druggist's get a little bichromate of potash. Put this in a two-ounce bottle of soft water. When the solution becomes saturated—that is, the water has dissolved as much as it will, pour off some of the clear liquid into a shallow dish; on this float a piece of ordinary writing-paper till it is thoroughly and evenly moistened. Let it become nearly dry, in the dark. It should be of a bright yellow. On this put the leaf; under it a piece of soft black cloth and several sheets of paper. Put these between two pieces of glass (all the pieces should be of the same size), and fasten them all together tightly. Expose to a bright sun, placing the leaf so that the rays will fall upon it as nearly perpendicular as possible. In a few minutes it will begin to turn brown, but it requires from half an hour to several hours to produce a perfect print. When it has become dark enough, take it from the frame and put it in clear water, which must be changed every few minutes, till the yellow part becomes perfectly white. Sometimes the venation of the leaves will be quite distinct. By following these directions, it is scarcely possible to fail, and a little practice will make perfect. The photographs, if well taken, are very pretty.—(*To-Day*.)

NURSERYMEN VERSUS AMATEURS.

I PERCEIVE in your last number two short paragraphs, the one headed "Brown's Wonder Strawberry," and the other "Blue Peter and Little Gem Peas," both of which appear to me to originate from the same pen, and the animus of which is unmistakable. It is evident to the simplest mind that the writer's object was not so much to speak of Brown's Wonder, as to shield himself under that heading to make an attack upon me and the productions of which I have the pleasure, and I hope the honour, to be the raiser.

Did I unwittingly give offence to Mr. Turner in my remarks upon Peas? If so, I beg to assure him that I had not the least intention so to do. I believe the Pea so generally known as Turner's Little Gem was the production of a professional brother, the late Dr. Maclean, of Colchester, and on that ground alone I should not have been so uncourteous to his memory. As to Mr. Turner, I never thought of him in the matter.

I have nothing to withdraw from my remarks on those Peas. Little Gem is so well established that no expression of mine would prevent anyone growing it who likes a very dwarf Marrow Pea. For my part I should prefer Alpha for an early, and some of the other better sorts of Marrow Peas for a later supply, and hence I discarded it long ago; but in the Imperial class—and this was really the object I had in view, not thinking so much of Little Gem as of Beck's Gem, Tom Thumb, &c.—I should prefer such a Pea as Blue Peter to wasting stakes on many others of that class no better in quality and not so productive for the ground they occupy. But as to Emperor of the Marrows, Mr. Turner's remarks more particularly surprise me. It is quite within the range of possibility that I may be as good a judge of Peas as Mr. Turner, albeit he is a nurseryman; and I can only say, that after testing many of the acknowledged best sorts of Peas with which my gardens have this year abounded, G. F. Wilson among the number, when the Emperor came to table everyone wanted to know what it was, and said with one voice, "This is the Pea"—the best Pea they had tasted. I believe the verdict to be a true one, and fearlessly assert that your readers may grow this Pea with the utmost confidence, that is (tastes do so differ) if they like a first-class Marrow Pea.

Now as to the matter chiefly in hand, the Strawberries. Mr. Turner's remarks carry absurdity on the face of them. He says, "How is it we never meet with Dr. Roden's gems, so temptingly described in your last number? They are never met with in good gardens, on the exhibition table, or in any catalogue." It is scarcely necessary for me to reply to the above illogical proposition by asking another question, How can the above results be achieved before the plants are even distributed? Can anything more pointedly show the jealousy Mr. Turner seems to entertain towards humble amateurs like myself dabbling, I suppose he would say, in matters we have nothing to do with, and overstepping the bounds of reason and even possibility to express his feelings? I think I may here say good-bye to Mr. Turner on the above head.

But he may say, "You had other seedlings temptingly described, and which have been before the horticultural world several years." Yes, but they were not described in the last number of the Journal, and it is not true that they are never met with in good gardens or in any catalogue. It is quite true that I did not seek the assistance of men of Mr. Turner's calibre to vaunt these seedlings, neither did I seek the good opinion of the Horticultural Society to bring them before the public. I doubt the expediency of the former for many reasons, even though it may possibly lead to exclusion from such valued catalogues; but I quite agree with the latter procedure, where leisure time and other circumstances conduce to such a result. I preferred, with my active life, to let my seedlings silently and unobtrusively make their way, assured that if there was merit it would as certainly be found out without any adventitious aid whatever, and what is the consequence? Those Strawberries, Early Prolific in particular, are to be found in many good gardens, are to be found in some of the best catalogues, and are gradually finding their way into others, several of which are now before me.

The best exhibition table, and the only one I covet or care about, is the table of the private gentry, and the good and great of the land, for whom my exertions in this department of the art are mainly intended, where the judges are not only competent but unbiassed, and not for the mere trader in plants. And that this course is being appreciated, I can now tell Mr. Turner for his gratification, that my gardener cannot grow Early Prolific and Duke of Edinburgh fast enough in my limited space, the former especially, for the numerous applications he has for these varieties from all parts of the country. And with regard to the two varieties now being distributed, it will be utterly impossible this year to execute the orders he already has on hand for plants, except by limiting the numbers. The aid of nurserymen, therefore, as mere vendors of plants, even to the dreadful exclusion from their catalogues, will not be necessary. At the same time be it understood, that those nurserymen who have applied to my gardener for plants will by my instructions be treated with every courtesy and attention, and their wonted privileges extended to them in the order of priority, as far as circumstances will admit.

Having so far justified myself from this uncalculated attack, I will not obtrude further on your valuable space on a subject which is foreign to your pages, and on which I feel I could not have troubled you, had you not inserted the articles in question. I will, therefore, conclude by saying that Mr. Turner may depend that I shall always be ready, and I trust able, to defend myself from all such illiberal attacks, whether they come in the form of satire or otherwise. Mr. Turner's allusion to my gems was, doubtless, very clever, but I think the term is so thoroughly appropriated by himself that no one else has any right to it, and I for one do not use it. On the other hand, if Mr. Turner doubts my integrity or the honesty of my statements, I shall be happy to extend the right hand of good fellowship, and to see him at Morning-side at any time during a Strawberry season. We all know that no fruit varies more with soil and situation than the Strawberry, but if Mr. Turner honours me with a visit, he can judge for himself, and if I have timely notice of his approach, I will try to give him a dish of the true Emperor of the Marrow Peas.—WILLIAM RODEN, M.D.

SIAMSE TWIN CUCUMBERS.—I enclose a photograph of an extraordinary freak of nature, displayed in the growth of what, I think, may be properly termed twin Cucumbers. A number of working men in this neighbourhood, interested in gardening and fond of Cucumbers growing, have raised a variety to which they have given the name of Benicia Boy, in allusion, no doubt, to the vigorous qualities of the American pugilist. I

understand the plant is a cross between the Irishman and the Telegraph. It is a very free bearer, but was not thought to be possessed of the power of producing such a freak of nature as that represented in the photograph, and the like of which has not been previously known in this district, nor, indeed, amongst gardeners of extended experience in many parts of the country. The present example is perfectly formed, and is not at all the result of pressure, as is so often the case.—S. LEECH, *Hollingwood, near Manchester.*

[The photograph represents the two Cucumbers united at the shoulder, but both attached to one and the same stalk. All fruits are liable to produce similar unions, as they are occasioned by two embryos being in the same flower.—EDS.]

PREVENTING CALCEOLARIA FAILURES.

I HAVE often noticed complaints of failures of bedding Calceolarias from one cause or another, including fly and weevil. For three years I have regularly bedded some five hundred plants, and have lost at least half of them, in hot weather especially, and mostly owing to fly. I determined, however, this year to try an experiment of my own, which has turned out most successfully. It is as follows. I mixed in a bucket a strong solution of Fowler's insecticide, heat about 100°, and in this solution dipped every plant overhead, before putting it into the ground, for about ten seconds. Out of over five hundred bedded this year I have not lost a dozen, and have not seen the slightest sign of weevil or fly of any kind upon the plants, and they have grown and bloomed most profusely.—JAMES RAILTON, *Rosclands, Fallowfield, Manchester.*

BEDDING PLANTS IN THE LONDON PARKS.

No. 2.

WE will now cross from the Green Park into Hyde Park, and after passing some very good beds on the right, near Apsley House, we reach Stanhope Gate, from which point to Grosvenor Gate there is a series of beds which are simply superb; there are great sheets of splendidly-coloured flowers and of leaf-plants, and the numerous beds are at once extremely rich in colour, uniform as regards growth, and absolutely free from blanks.

From Stanhope Gate to South Street Gate the oblong beds on the right between the Plane trees are margined with Golden Feather Pyrethrum and edged with Iresine Lindeni, the dark, lanceolate, entire leaves of which offer a striking contrast to the beautifully cut golden foliage of the Pyrethrum. On the left-hand side next the park, the oblongs with rounded ends are margined with *Echeveria secunda glauca*, and edged with *Dactylis glomerata variegata* and Blue King Lobelia planted alternately, and which produce a light and elegant effect. There is then an inner line of *Alternanthera amabilis latifolia*. The small circles round the Oaks are margined with *Sedum glaucum*, and edged with *Alternanthera amœna*, and the remaining space is filled with *Mesembryanthemum*. The oblongs next the boundary, though their position between the trees is unfavourable, are so good that all deserve particular mention. The first is filled with Duchess of Sutherland Geranium; the second with the silvery-leaved Queen of Queens mixed with *Verbena venosa*; the third with *Lucius*; the fourth with Mrs. Pollock mixed with Blue Perfection *Viola*, a very effective combination; the fifth with Warrior, a magnificent scarlet bed; the sixth with Gaines's Dwarf Calceolaria; the seventh with Christine; the eighth with Paul's Bonfire, literally a blaze of flower; the ninth with Gaines's Calceolaria; and the tenth with Wellington, a fine dark crimson, but not at its best. The remaining four beds consist of Crystal Palace Gem, *Heliotrope Jean d'Amour*; James Richards, bronze Geranium, very fine as a bedder; and Stanstead Rival, which forms a splendid glowing crimson bed. Turning backwards, again on the right, next the park, the first oblong is Model Geranium, a neat, compact, golden-bronze kind, but which we shall discard another year, and the result here accorded with our own experience, as the bed of it is inferior to the rest in the series. Next to this is Rose Bradwardine, one of Mr. Pearson's raising, a beautiful and very pleasing deep rose, this is extremely fine. The next bed is one of the finest in the series, Crystal Palace Gem Geranium, with a centre of *Coleus Verschaffelti Improved*, perfectly even throughout, and which is much more brilliant in colour than the old form when thus seen in mass. A splendid bed of Glow comes next, followed by Mrs. C. Custons,

and then with Variegated Stella Geranium mixed with Purple Queen *Verbena*. A fine bed of Mrs. John Lee, of a deeper bronze than James Richards, comes next, and then a bed of Crystal Palace Gem centred with the Improved *Coleus*. The remaining two beds are of *Amaranth* (Pearson), deep pink, with splendid trusses and very fine in colour; the other being Mrs. Pollock mixed with Blue Perfection.

We now come to a fresh series of beds, that from the South Street Gate to the Mount Street Gate. In this the margin to the beds on the right-hand side is of *Veronica incana*, the edging of *Lantana Selovii*; whilst on the left, as far as the Elm tree, the margin is *Echeveria secunda glauca*, the edging *Mesembryanthemum cordifolium variegatum*, with an inner line of *Alternanthera amœna*. The circles are the same as in the previous series. From the Elm tree to the Mount Street Gate the margin is *Mesembryanthemum deltoideum*, with an edging of *Alternanthera magnifica*, and an inner line of Robert Fish Geranium. Among the beds of Geraniums there are very fine ones of Editor; Artemus Ward, a narrow-zoned Golden Bronze, very neat and even; Princess Alexandra, silver-edged, very pure white; Glow; Louis Roesler, deep rose, changing to soft rose, trusses very large, and forming a fine mass; Perilla, Scarlet Gem, *Lucius*, Christine, and Bayard, splendid. With these are some beds of Calceolarias, but as Gaines's Dwarf is the only one grown, we need not notice this flower further.

We will now take the inner, or park side, backwards towards South Street. The two heart-shaped beds at the end are planted with Lady Plymouth white-variegated Geranium, interspersed with Blue King Lobelia. The oblongs which follow are in pairs as regards colour, or as nearly so as possible. The first pair consists of rich masses of *Coleus Verschaffelti Improved*; then come Pearson's Florence Durand and Cleopatra, beautiful deep rose; next, La Vestale, white, which is better than its companion Madame Vaucher; then *Coleus Verschaffelti Improved*; and finally the two heart-shaped beds at the end are planted with Bijon, white-variegated Geranium, mixed with Lobelia Lustrous, deep blue. This is a very striking series of beds, those of the *Coleus* in particular being admirable. From the Elm tree, backwards still, are fine beds of Golden Circle and Golden Nugget Geraniums, respectively intermixed with *Viola Blue Perfection* and Charming, and others of remarkable beauty, planted with *Coleus* and Centaurea.

Starting again northward from Mount Street to Grosvenor Gate we find the beds on the right are margined with *Alternanthera magnifica*, and edged with Sportsman *Verbena*, rosy purple; while those on the left are chiefly margined with *Echeveria secunda glauca* and edged with *Mesembryanthemum cordifolium variegatum*, within which is a line of *Iresine Lindeni*. The heart-shaped beds, however, are margined with the Californian Houseleek. In the long beds on the right Rubro-cinctum, Bonfire especially fine, and *Lucius* are the most conspicuous for free-flowering among the Geraniums; but we must not omit to notice charming beds of *Centaurea candidissima* mixed with *Verbena venosa*, and a scroll of Mrs. Laing silver Tricolor Geranium, which is magnificent. Turning backwards we have a fine heart-shaped bed of W. Sanday, golden Tricolor; then follow oblongs in pairs of White Star and Flower of Spring, Mrs. Milford and Golden Chain, Jean Sisley and Leonidas, Albion's Cliffs intermixed with Blue King Lobelia, along with Lady Plymouth similarly blended. Then come Chilwell Beauty and Duchess of Sutherland, both very fine but the former taking the lead. Four heart-shaped beds round the Rhododendron clump are beautifully finished-off. These are planted with *Impératrice Eugénie* Geranium, golden bronze, interspersed with Lobelia Lustrous. There are, besides, two circles of Mrs. Upton, pink, fine; and then we come to an oblong of Violet Hill Nosegay, and Vesta, dark crimson scarlet, extremely free. Next follow Artemus Ward and Mrs. Pollock, and then Mrs. Laing and the Rev. F. F. Fenn, the latter with splendid crimson trusses, large and freely produced; and then we have Madame D. Bertrud, deep pink with a white eye, paired with Pink Nosegay; followed by beds of Black Douglas and James Richards of the Bronze class, the former very effective by its deep blackish zone. Of William Thomson there is a magnificent bed; the colour of the flowers, a magenta-flushed rosy crimson, being splendid, while the trusses are not only good but very freely produced. Lawrence Heywood, in the way of Duchess of Sutherland, is also very good. There is a charming bed of Golden Harry Heever; and the heart-shaped beds at the end are most effectively planted with Bright Star

and Countess of Warwick, the one silver-edged, the other a silver Tricolor Geranium, intermixed with Lustrous Lobelia.

From Grosvenor Gate to Brook Street, and thence to the Marble Arch, the beds are numerous, but not so close together owing to the number of trees and shrubs. Although the planting is tasteful and well executed throughout, we shall not enter into details. There are excellent beds of Abutilon Thompsoni interspersed between Colens aureo-marginata, of Titian Geranium, and of Mrs. Kingsbury, silver Tricolor, edged with Lobelia, and margined with Golden Feather Pyrethrum. From Brook Street to the Marble Arch the beds are margined with Alternanthera magnifica, and edged with Lobelia Blue King, and among them are some very beautiful circles and rounded oblongs. We noticed Ianthe Geranium, one of Dr. Denny's raising, as especially splendid both in colour and size, combined with profusion of bloom. There are likewise several admirable beds of Coleus.

EXPERIMENTS IN POTATO CULTIVATION.

We take the following account of some very interesting experiments made by Mr. J. V. H. Scovill, of Paris, Oneida County, New York, from the report of the Department of Agriculture of the United States:—

Many practise the habit of selecting only small Potatoes for seed, reserving those that are merchantable for sale. Others plant medium-sized Potatoes, cutting only the largest. Some practise shallow planting; others plant more deeply and dig them with a machine. I have made some experiments during the past season to ascertain, if possible, what is the best kind of seed to use. The ground used for this purpose was a clay loam, and was an inverted green sward, ploughed about 7 inches deep. The Potatoes were planted in hills, the rows being 3 feet by 2 feet 9 inches apart, making 5280 hills to an acre. The number of hills planted of each kind was seventy, and the result figured-out as if by the acre. The seed was carefully weighed, both at the time of planting and at the time of digging, and was estimated at the rate of 60 lbs. to the bushel. The rows were marked with a horse-marker, and the seed covered about 2 inches deep. The variety experimented with was the Garnet Chili, a variety largely cultivated in Central New York for local marketing. They were planted June 1st, and harvested October 21st.

No.	Seed used per Acre.	Total products per Acre.			
		Bush. of 60 lbs.	Bush. of 60 lbs.	Bush. of 60 lbs.	Bush. of 60 lbs.

20	One large Potato in a hill, with eyes dug out . . .	35	114	14	128
	Field crop	151	38	184
	Field crop, Peach-blows	194	21	215

Some very interesting and curious facts are observable from a perusal of the foregoing table. The strongest seeding, in almost every case, furnishes the most flattering results. The largest yield were those of Nos. 9 and 19, 230 bushels to an acre, and a difference of about 17 bushels in amount of seed used, while the proportion of small Potatoes was unusually large. The best proportion of large Potatoes was in Nos. 2, 4, and 5, and largest amount in No. 18. Two eyes to a piece, and two pieces in a hill, and three eyes to a piece, are better than two single eyes; while three eyes to a piece, and two pieces

in a hill, give eleven bushels less of large ones than a single piece of the same number of eyes, and nearly double the number of small ones, as will be seen by referring to Nos. 5 and 6.

I find this minute in my memorandum at the time of planting, referring to Nos. 5 and 6:—"The labour of cutting with three eyes to a piece is increased, and most of the seed ends thrown out." Also of Nos. 7 and 8:—"Seed ends left in and generally divided, and sometimes more than four eyes to a piece, and less care in cutting." No. 20, one large Potato, eyes dug out. Of the seventy hills planted ten did not grow, and three of these were dug up and destroyed by fowls. I am satisfied that the proportion of those which did not germinate would have been less had the planting been earlier. Everything which resembled an eye was carefully dug out, and the Potatoes were all carefully examined by other parties previous to planting. What does it prove? It proves the wonderful vitality of the Potato, and that the cutting and planting may be done with a machine without fearing any material risk or damage from missed hills.

From the result of these experiments my previous opinions are confirmed, and I would say, Use good seed, and avoid the danger of a depreciating quality by feeding the small ones to your stock. I usually plant a good medium-sized Potato, and, if large, cut it once in two lengthwise. The "field crop" noticed was grown alongside the above, and was, I think, less than my general crop.

These Potatoes were grown in the town of Paris, Oneida County, New York, in an elevated locality, 1500 feet above the level of the sea.—(Canada Farmer.)

USING STONES IN POTTING.

HAVE any of your readers ever used stones purposely in potting such things as Vines and Pines? It is the custom to pick these carefully out of the compost before using it; and I confess, myself, to a prejudice against them hitherto, though I am not prepared, I must admit, to give a very good reason for the same. I am led to ask the above question from an idea which occurred to me the other day when examining the roots of a Pine Apple plant which had been turned out of the pot. As has often been observed in the case of potted plants, the roots were all at the side of the pot. Just to see how far they had availed themselves of the body of soil between the stem and the pot, I poked the soil out at the bottom of the ball from the top. So few were the roots, comparatively, that this could be done easily, leaving just the skeleton of the ball—a thick mat, which had formed at the sides of the pot, and inside nothing but a few strong roots radiating from the stem of the plant to the outside of the ball, where they had congregated and thickened, without the least disposition to turn back and take advantage of the bulk of rich soil they had left behind. I estimated that the roots had availed themselves of about one-third or one-half of the soil in the 12-inch pot, living principally—after they had eaten the strength out of this—upon the nourishment supplied in the waterings. No doubt it was observation of this kind which led to the practice of shifting plants forward by inches, in order that the roots might be compelled to eat their way through in a regular manner; and there is reason in the practice, though in the case of the Pine Apple the many-shift system is not a good one. Still, if by any other practice we could produce the same results it would certainly be advantageous. If a good plant can be grown in a 12-inch pot upon only one-half the diet supplied, it would doubtless be a much better specimen if it could be induced to take it all; and a 10 or 12-inch pot contains no more soil than a strong Pine plant requires, but it is unable to avail itself of the store under the circumstances, and it is therefore lost. It is the same with pot Vines and other plants, but to a less extent, perhaps; for the Pine has a very bad habit of warping its roots round the sides of the pot, especially when it is potted loosely. It would appear, therefore, that to make the roots occupy the soil in the pot regularly as they progress, they must be obstructed in their passage. Hard potting will do this to a great extent, but it is not entirely effectual in preventing the majority of the roots from establishing themselves at the side of the pot. It seems to me, therefore, that a fair proportion of stones among the soil would effectually bar their direct progress. Round boulders would be too bulky, but flat slaty stones, introduced vertically here and there between the stem and the pot at potting time, would necessarily cause the roots to break up into branchlets and seek a more roundabout way to their ultimate destination—utilising, at the same time, the

body of soil at their disposal, which they would otherwise have disregarded.

Supposing we could accomplish the end in view, it seems certain that less-sized pots would do, and two pots of a given size would give better results. I have frequently noticed, as others must have done, that the ball of an old Pine plant when squeezed with the foot, would burst its skin, and the contents, soil and bones, scarcely touched with a root, would fall out in much the same condition as when the plant was first potted, except that the bones in the soil were just in that state in which the roots like to find them for immediate use.—J. S.—*(The Gardener).*

NANT,

THE PRINCIPAL FLOWER GARDEN OF BARON HILL,
THE SEAT OF SIR RICHARD BULKELEY WILLIAMS BULKELEY,
BART., BEAUMARIS, ANGLESEA.

To us this is an establishment quite unique, and as beautiful as singular. It is at the base of wooded heights sheltering it from the strong prevailing winds, and its name, *Nant*, a dingle, well describes its position. It is about a mile from the mansion, and hither Lady Bulkeley resorts almost daily; it may be regarded as her boudoir, and in the two rooms of the little villa, the windows of which admit a view of the entire garden, her ladyship receives visitors, and has her "five-o'clock tea." There is a brightness and elegance characterising the whole that render it most attractive. The entrance is from the road

Nant. What Mr. Gough has to accomplish with his present glazed structures will be estimated justly when we add that the Nant garden requires nearly 14,000 plants, and Baron Hill garden about 10,000, exclusive of potted plants for the conservatory, verandah, and house. We have but one other suggestion to make, and we daresay that he is as fully aware of it as we are—climbers will never flourish in the little conservatories in front of the Nant villa until better top ventilation is secured to them. The whole of the uppermost panes of the roofs might easily be fitted into a hinged frame, and they would not allow of too free a current of air.

ARUNDO CONSPICUA.

ALTHOUGH this plant has been known for many years, it has certainly not yet received that attention which it merits, for it is seldom we meet with it, although its rival the Pampas Grass is plentiful enough. Whether it is that a plant which is in beauty more than two months earlier than the Pampas Grass, and at a time when the garden possesses other attractions, is thought of less value on that account, or that an idea has got abroad that the plant is not very hardy, or is difficult to manage, I know not. It is, however, more likely that the plant is not sufficiently known. Certain it is that this fine *Arundo* from the Antipodes is not met with so often as it ought to be; it flowers early in July, and its numerous spikes or heads resemble the Pampas Grass in every way, are often as large, and are produced on stems which are, on the whole,

NANT.

from Beaumaris by Llanfraes church, beyond which church it is about half a mile. The public are admitted three days in the week—Tuesday, Thursday, and Saturday, between the hours of ten and two. The garden is about three-quarters of an acre, and is arranged and planted as in the annexed plan. It is one of the brightest, most varied, and best planted flower gardens we ever inspected. It is highly creditable, as is all the gardening connected with Baron Hill, to Mr. Gough, the courteous head gardener, and we hope when next we visit Beaumaris to find him in a more suitable residence, and with more glass houses, somewhere between Fryars and Nant; he would then be better able to supply the demand for flowers, and without that consumption of time required in passing over the too-long distances between Baron Hill, Fryars, and

taller than those of that popular autumn ornament. What is of more consequence, they are even more spreading, a greater proportion of them rising diagonally on all sides of the plant as well as upright in the centre, giving it as uniform a character as the most fastidious dresser of plants for an exhibition could desire.

The plant has a strong resemblance to the Pampas Grass, but is somewhat broader-leaved, and, perhaps, does not rise quite so high, so that a greater portion of the flower stem is seen above the plant than is shown in its compeer; its foliage is also not so rough, but in all other respects the plants very much resemble each other. From the difference in the time of flowering we are in the habit of naming the one the summer and the other the autumn Pampas Grass, still it must not be

inferred that as the *Arundo* blooms so early it necessarily is soon over. On the contrary, there are few plants that I know which continue longer in a showy condition, and it is not too much to say that it often looks well up to the middle of October, after which, however, its appearance will not compare with the newly-developed plumes of its neighbour. Up to the end of August its beauty can hardly be said to be impaired; in fact, I might add, that at the present time (August 13th), some spikes that were fully out in the first week of July look better than they did three weeks ago. As regards hardiness it may also be placed in the same list as the Pampas Grass, for some of our plants have occupied the same position, and that a fully exposed one, since 1866, without protection of any kind, the situation being somewhat dry—too much so, I believe, for well-developed spikes or plumes, and yet even in that position it is but little inferior to the best examples of the Pampas Grass. Its flower spikes may not be quite so numerous, as I have not been able to count more than forty on one plant. I strongly advise those who have not yet grown this Grass to procure it, and whether as a single object on the lawn, or in front of a shrubbery, its appearance when in bloom is equally graceful.—J. Renou.

PLANTS AS DOCTORS.

In addition to the pleasure that may be derived from floriculture, the sanitary value of flowers and plants is a feature of the subject so important as to call for special mention. It was known many years ago that ozone is one of the forms in which oxygen exists in the air, and that it possesses extraordinary powers as an oxidant, disinfectant, and deodoriser. Now, one of the most important of late discoveries in chemistry is that made by Professor Mantegazza, of Pavia, to the effect that ozone is generated in immense quantities by all plants and flowers possessing green leaves and aromatic odours. Hyacinths, Mignonette, Heliotrope, Lemon, Mint, Lavender, Narcissus, Cherry, Laurel, and the like all throw off ozone largely on exposure to the sun's rays; and so powerful is this great atmospheric purifier that it is the belief of chemists that whole districts can be redeemed from the deadly malaria which now infests them, by simply covering them with aromatic vegetation.

The bearing of this upon flower culture in our large cities is also very important. Experiments have proved that the air of cities contains less ozone than that of the surrounding country, and the thickly inhabited parts of cities less than the more sparsely built, or than the parks and open squares. Plants and flowers and green trees can alone restore the balance; so that every little flower-plot is not merely a thing of beauty while it lasts, but has a direct and beneficial influence upon the health of the neighbourhood in which it is found. Surely, it is a beautiful provision of Nature that something which is at once the most dainty of occupations and most delightful of amusements should be intimately bound up with the solution of problems so important as the health of our cities and the redemption of fever-infected districts in the country.—(*Appleton's Journal*.)

NOTES AND GLEANINGS.

We have received an official extract from the *London Gazette* of the 26th of August, which records the list of awards in the British section of the VIENNA UNIVERSAL EXHIBITION, and are well pleased to see that in Group 2, "Agriculture, Horticulture, and Forestry," Messrs. Carter & Co., High Holborn; Gibbs & Co., Mark Lane; Lloyd, Grantham; Sutton and Sons, Reading, had awarded to them medals of the highest class for "Progress," when their productions are compared with those of previous exhibitions.

A CURIOUS contribution to the literature of that excellent and mournful root, the ONION, comes from a little French village. The inhabitants of this place regularly perform a ceremony without which they hold the general well-being of the said vegetable could not be secured. This ceremony consists in the gorgeously-attired people of the village dancing in a circle, holding hands; and is said not only to make the Onion healthy, but to impart to it a fascinating roundness and perfection of form. The festival continues eight days, and is accounted generally pleasant and profitable.—(*New York Tribune*.)

A WRITER of experience states that he has found no trees that succeed so well by the seaside as PINUS INSIGNIS and the CORSICAN PINE. He has plants of the latter growing and

flourishing where the Sycamore and Beech, twenty years planted, never could even get into respectable bushes. The Pines named also have the advantage that hares and rabbits will not touch them, and the wood of the Corsican Pine is very valuable, while that of the Austrian, another great tree for the seaside, is worth but little. He has also succeeded in growing the Aleppo Pine (*Pinus halepensis*), from seeds brought from the Isle of St. Marguerite, opposite Cannes, where this Pine grows with its roots down to the salt water, and where it withstands the most terrific sea gales without seeming a bit the worse for them.—(*New York Tribune*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

A GREAT change has taken place in the weather, and frequent showers have greatly refreshed vegetation; therefore, now is the time to be busy with the hoe in earthing-up the various crops that require it, and also for planting those that from the dry state of the weather could not be planted out before. Prepare ground for spring Cabbage, and also for hand-glass Cauliflowers. Where Broccoli has not been sufficiently planted, large plants may yet be put out with success. They should be laid-in with a spade in a slanting direction; earth-up the advancing crops. Earth-up *Cardoons* for blanching in favourable weather. Continue to earth-up the early crops of *Celery* carefully to the tops of the plants, and they should always be dry at the time. The crops that have not yet been earthed-up should be kept very moist. Those *Cucumbers* in frames which it is intended to keep in bearing, should be covered-up when the nights are cold, the beds should also be newly lined. Continue to blanch *Endive*, and plant-out from successional sowings. Another sowing of the various sorts of *Lettuces* may be made. It is always better to have a superfluity in the spring than otherwise. *Mushroom* beds may now be made, either in sheds or in the open air. Thin the summer sowings of *Parsley* when in a young state, the plants will then gain strength to stand the winter. A portion of the spring sowing should be cut down. Gather the fruit of *Tomatoes* as it ripens, remove all the shoots that shade it, also some of the leaves.

FRUIT GARDEN.

As soon as the fruit is gathered clear away the old wood from Raspberries, also any extra shoots left at the summer thinning; tie the young shoots to stakes or rails, and if very long pinch-off their points, but do not shorten them too much now, as from the exposure of the pith a severe winter would be apt to make the canes shorter than you wish to have them at spring pruning. Fork-in a coat of manure, for, like the Vine, the Raspberry delights in rich feeding. If the above course be adopted you will be rewarded with well-ripened prominent buds for next season. Vines, attend to the directions previously given, thin-out all useless shoots, remove leaves where they are too thick, and where you do not want the buds in the axils for next season; but while exposing the bunches to more light, be careful to leave a sufficiency of leaves to shade from the direct influence of the sun's rays. Pay attention to the ripening fruit, gather it immediately it is ripe, and use every means of destroying insects which attack it. Where wasps are numerous bottles half-filled with some sweetened liquor should be hung about the walls. Continue to plant-out Strawberries, good strong runners of which may now be procured from the old beds.

FLOWER GARDEN.

Now that the weather is favourable it will be as well, where such convenience is required for the preservation of the more hardy of the tender plants through the winter, that provision be made for the formation of a good-sized temporary pit. Turves of dry peat, where they can be readily procured, are as good a material as can be used, but in the absence of them, turves of a loamy nature will be found a good substitute. The situation where the pits are built should be dry and sheltered, and the turf walls should not be less than 15 inches thick. Make the walls firm as you proceed, and when of the requisite height dress the sides off square and neat with an old hay-knife, or some other instrument. The turves of the top layer must be secured in their places by driving pegs through into the lower ones; and if the whole of the walls of the pit could be covered with patent asphalt roofing, which is a very inexpensive material, they would be rendered doubly secure, as so long as they are dry there is no fear of frost penetrating; but if they become wet, which the asphalt would prevent, their protective influences would be greatly deteriorated.

GREENHOUSE AND CONSERVATORY.

The management of the conservatory will be more uniform now than in summer. No syringing will be necessary unless for a plant here and there which may require it for keeping down insects. Where blinds have been in use to keep off the sun they cannot yet be dispensed with altogether, but use as little as possible from this time. Get all the watering done in the

morning, and give no more of it to any of the stove plants which are brought into this house for their flowers, than just enough to keep them from drooping their leaves. The few species of Lantana which we cultivate in this country, are well suited for flowering in this house in the summer and through the autumn, and there is no doubt some kinds of them would interbreed and make fine hybrids. There are between forty and fifty sorts of Lantanas in the Berlin Botanic Garden, many of which, no doubt, would be welcome in this country, and might be easily procured through the nurserymen. The old *Turnera elegans* is a very useful and gay plant, it flowers from April to October in the conservatory, and even out of doors in summer, but it requires a house rather warmer than a greenhouse in winter, and is the first to go off in damp winters. Young plants of it in small pots well drained and filled with sandy loam only, might now be put in a spare Melon frame to ripen them off. When they have filled the pots with roots harden them by admitting plenty of air. In winter place them on a shelf near the glass in a cool part of the stove.

STOVE.

The beginning of September, when night fires will be necessary in dull or cold weather, is a critical time for stove plants. The house must now be kept more close, air being given in the middle of the day. An increase of heat by artificial means is more likely to retard the ripening of plants now than if they were left cool and dry. The thermometer should not, however, be allowed to fall below 60° for the next six weeks, and during this time it is of as much importance to keep the atmosphere of the house dry as in the dead of winter. These rules, however, do not apply to plants whose habit is to grow in winter, as in the case of many bulbs, Orchids, and a few other plants. *Clerodendron splendens* is one which grows late in the autumn, and may now be encouraged; it will flower for a long time in winter, and established plants of it should not be forced to grow in the spring or early summer. Like some other plants, it requires a long time of rest after flowering. Prune and tie-in the climbing plants, and prepare for those plants which have been placed in the conservatory.

PITS AND FRAMES.

Keep up a gentle heat in the cutting frames; give air to allow the cuttings to dry; pot-off seedling plants, and also rooted cuttings. Always use very small pots for the purpose at this season of the year.

FRUIT ROOM.

Put this in good order for the reception of fruit, and gather not only the finest wall fruit as it ripens, but also some favourite Apples and Pears, so that by sweating part of them by dry, sweet hay, you will be enabled to prolong their season. Keep the fruit room cool and airy in order to allow of the escape of moisture given off by the fruit, which is considerable for a few weeks at first. Look over the fruit remaining out of doors frequently, and gather it as it becomes fit. Also examine that stored in the fruit-room, as there will occasionally be found a few decaying for some weeks after housing, and these should be removed as soon as possible.—W. KEANE.

DOINGS OF THE LAST WEEK.

We have had hazy weather accompanied by drizzling rains—weather especially favourable for the spread of the Potato disease, and, as a consequence, it is showing itself in the haulm, which is much affected in places. No diseased tubers have as yet been found.

FRUIT AND KITCHEN GARDEN.

The young *Strawberry* plants which were put out early in August are making rapid progress, consequently they produce runners freely; these are not allowed to remain, but are pinched off once a-week. A large crop of weeds was springing up between the rows, and the Dutch hoe, run through amongst them, loosened the surface, which had become caked by the heavy rains, and the weeds were thus destroyed. We saved a small bed of old plants, which were treated in the following manner: All outside leaves and runners were cut away from the plants, the ground had become quite matted with runners and the leaves of the old plants; these were cut up with a draw-hoe. The ground was then raked over with a small rake, and a dressing of decayed manure applied. Except hoeing to keep down weeds, no other attention is needed.

We are attentive to gathering Apples and Pears as they ripen. It is better to gather Pears before they become quite ripe, and where the collection is limited, two or three gatherings at intervals of five or six days will prolong the season of certain sorts. Of Williams's Bon Chretien, than which there is no better bearer as a standard, bush, or pyramid, the first gathering has just been made. This fine Pear is mealy, and has a disagreeable flavour if allowed to remain on the trees until the fruit is quite ripe.

Keep the hoe at work amongst all kitchen-garden crops, such as Sprouts, Broccoli and Coleworts. Cleared off Pea haulm after the peas had been gathered, and dug over the ground.

This takes very little more time than it does to hoe and rake the ground, and it is, besides, better for succeeding crops.

CONSERVATORY AND PLANT STOVE.

In these structures we admit more air, and do not shade so closely, as it is highly desirable to have the wood well ripened for the winter. We have repotted all Ferns requiring it, and small specimens of hardwooded stove plants have had a final shift for the season. Such subjects as *Ixoras*, *Gardenias*, *Dipladenias*, &c., should not be stunted for pot room in the earliest stages, if healthy handsome specimens are desired. We have been washing the leaves of Orchids and some other plants on which mealy bug had appeared; we use only clear rain water and soft soap. Training climbers in the conservatory, such as *Lapageria rosea* and *L. alba*. These are by far the best autumn-flowering greenhouse climbers, and under proper treatment they are of very free growth. One often sees them in an unhealthy condition, and on looking for the cause it will be found in the potting material used. Many persons pot them in turfy loam, or loam and peat mixed together, neither of which composts suits them. We have grown both varieties (and of the two *L. alba* is, perhaps, the stronger grower), for many years in turfy peat, and sand if the peat does not naturally contain enough; and the pots used should be large in proportion to the size of the plants. A good supply of water at the roots is essential; the leaves should likewise be freely syringed at least once a-day in summer. Under such treatment thick fleshy roots will be formed, and strong shoots as thick as a man's little finger will be thrown up from the base. Amateurs ought not to be deterred from purchasing this fine plant owing to its being difficult of cultivation; it is one of the easiest grown of plants treated as above.

Typing and Training Chrysanthemums.—We grow a great number of this useful winter flower to fill our large orchard house. The largest proportion are grown specially to produce fine flowers; we pot three plants in an 11-inch pot, or two in a 9-inch pot; each plant will bear from six to nine flowers, and the treatment requisite to produce these causes the plants to grow very tall—from 5 to 8 feet. They require very stout sticks, otherwise the shoots are damaged by the wind. Dwarf-trained specimens, both of the large-flowered and Pompon sections, are now being trained; the shoots have to be much bent to get the plants into a dwarf character, but it is bad management if the bent shoots are conspicuous when the plant is in flower. A handsome specimen fit for the exhibition-table should present a rounded surface of foliage and flowers. The flowers, standing well up above the leaves, should be of large size and well-shaped, as one good flower on a specimen plant is worth a dozen inferior ones. As soon as the buds were visible we watered with weak liquid manure water. A pinch of guano in the water-pot suits them well.

FRUIT AND FORCING HOUSES.

Pinerias.—We have a fair supply of nice fruit from our small houses, and it is of good quality, a sure sign of which is that it keeps well after it is ripe. Some Queens cut and laid in a box in the fruit room, which box was very nearly air-tight, were quite as good at the end of fourteen days as when they were cut. We have done nothing to the plants except attending to watering them, and this in the autumn requires much care; it is better to give them too little moisture rather than too much.

Vinerias.—In the late houses a few berries had become cracked very slightly at the apex; these were cut out, as they soon mould, and if not attended to will damage the sound berries. We have not used any artificial heat this year to ripen the fruit, not even in the Muscat house, and the fruit is, we think, as good or perhaps better than we ever had it when more fuel was consumed. Alicante, Mrs. Pince's Black Muscat, and Muscat of Alexandria are all that can be desired. Gros Guillaume has not ripened so well, but if we find the first-named three do succeed perfectly in ordinary seasons without any artificial heat, the last will be cut out, as it is not first-rate in every respect. The Vines make but little growth now, and little attention has been required as regards pinching and training the shoots. Pot Vines, which had made good growth in one of the Pine houses, have been turned out of doors; we like to see the wood quite brown and hard before turning them out. A sure sign of the wood being ripe is the leaves at the base taking on an autumn tint. Now is a good time to bud Vines. Inarching is best done in summer, when the wood is green and the Vine in full growth. Grafting should be performed when the Vines start into growth in the spring.

Strawberries in Pots.—The latest of these are now being potted. The sorts are mostly new; and it may be noticed here that when a new sort is introduced it has every justice done it. A large number of plants, say fifty, more or less, are planted out, and a similar number are grown in pots, and compared with the old-established sorts, and very few stand the test of this mode of comparison. Mr. C. Turner asks in last week's Journal how it is we never meet with the varieties raised by Dr. Roden. Early Peonie, Duke of Edinburgh, and I think another of his varieties were tested here, and not being of any great merit were thrown out. It is late now to pot them, but

we shall obtain from six to twelve good fruit from each plant—enough to test their merits. We have a great many sorts on trial this year, and should any possess distinct, novel, and good features, we shall be glad to recommend them. All our runners were later this year, but the earliest are now making good plants. We look the plants over once a week to destroy a small green caterpillar which feeds upon and disfigures the leaves, and also to pinch-off the runners, which are freely produced.

ORCHARD HOUSE.

We can only repeat what was stated last week. We have abundant supplies of Peaches, Nectarines, Pears, and Plums. It is astonishing what can be done to supply a succession of fruit from pot trees. This system of culture has its advantages and disadvantages. It is true that fruit of the very best quality, and size with quality, can be obtained; a large number of varieties can be grown, and by removing some of the trees out of doors as soon as the fruit is set a longer succession can be obtained. There is, on the other hand, one serious drawback, and it is of no use disguising the fact, that they require unremitting attention as regards watering, and when the trees are in full growth an hour or two of neglect will ruin them for the season. Prince and Princess of Wales Peaches are now coming in, as well as the later Nectarines, such as Albert and Rivers' Victoria. We continue to pot any trees that have been cleared of their fruit.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Hyacinths, Narcissus, Tulips, &c.*

T. S. Ware, Hale Farm Nurseries, Tottenham.—*Catalogue of Bulbs and Hardy Tuberos-rooted Plants.*

Carter, Dunnett, & Beale, 237 and 238, High Holborn, London, W.C.—*Carter's Catalogue of Flower Roots, Fruit Trees, and Roses.*

W. Clibran & Son, Oldfield Nursery, Altrincham, Cheshire.—*Catalogue of Dutch Flower Roots, &c.*

Dickson & Robinson, 23, Market Place, Manchester.—*Catalogue of Hyacinths and other Dutch and French Flowering Bulbs.*

W. Rollisson & Sons, The Nurseries, Tooting, London, S.W.—*Supplement of New, Choice, and Popular Plants to General Catalogue, 1873-74.*

John Harrison, Darlington.—*Catalogue of Flower Roots.*

George Poulton, Angel Road, Edmonton, London.—*Catalogue of Dutch Flower Roots, Vegetable and Flower Seeds, &c.*

William Ramsey, Joyning's Nursery, Waltham Cross, London, N.—*List of Bulbs, Hardy Plants, Roses, &c.*

TO CORRESPONDENTS.

* * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

BOOKS (*J. G.*).—Johnson's "British Ferns" enables in plain language anyone to detect the name of a Fern without a magnifier. You can have it free by post if you enclose 3s. 9d. in stamps with your address. (S. S.).—The "Cottage Gardener's Dictionary" will furnish you with information. Let us warn you that your suspicions are not justified by our experience, and you will find that a usual mode of rendering anyone untrustworthy is to show him that you mistrust him.

SEEDLING GERANIUM (*C. la Bota*).—The petals were all shed, but we could perceive that the tips and entire truss are large and the scarlet very bright.

FRUIT FOR WEST WALL (*G. M. E.*).—As you reject Pears you may have Black Tartarian, Bigarreau, and Belle Aigle Cherries. The last-named variety has the great merit of not being touched by either birds or wasps, and hangs very late.

BOTANICAL DRAWING (*Mrs. L. G.*).—Your query will be answered by the following extract from Burbridge's "Art of Botanical Drawing." We advise all who wish to draw plants and flowers correctly to buy the book. Its price is but one shilling. It is well illustrated. "In making botanical drawings everything should be clearly shown, and there must be as much variety in the position of the leaves and flowers as possible. Many leaves are smooth or glabrous in front and shaggy behind, this peculiarity must be correctly represented. In defining the margins of woolly leaves or leaves of great substance, the student will find a soft pencil give a much better effect than a very hard one, while a hard pencil is best for the definite outlines of flowers and their dissections. Be particularly careful to show the petioles of some of the leaves, and carefully note whether the leaves are arranged alternately, opposite, ver-

ticillate or distichous, and also note if they are furnished with stipules or other appendages, as hairs, warts, or glands on the petiole or lamina; if there is evidence of these being present, carefully examine them through your pocket lens (an indispensable companion to the botanical student and draughtsman alike), and if their being borne by the species is unusual, carefully represent them in your drawing, magnified when necessary, so as to be easily observed and noted."

SEEDS OF FLANDERS SPINACH (*H. R. Q.*).—The seeds are smooth, and any sent to you with prickles are either of another variety or a cross-bred. Mr. Keane in this Journal said that "the seeds are nearly round and smooth," which is totally distinct from "very prickly." In the "Bon Jardinier," the best of authorities, the Flanders Spinach (*Epinard de Flandre*, is especially described as one of the smooth-seeded kinds; and so it is by another good authority. Mr. Thompson, in his "Gardener's Assistant," who adds—"Leaves large, hastate, from 6 to 8 inches in breadth." Grow plants from the seed sent to you, and if they do not agree with this description give the seedsman "the right end of the stick."

FUCHSIA LEAVES BROWNED (*R. S. S.*).—The Fuchsia leaves you sent have shown no trace of being now or lately attacked with insects, and we should therefore consider the plants have suffered from want of water and the bright weather. The plants not having been shaded may have been the cause of the mischief.

INSECTS ON GENISTA (*Idem*).—It is an aphid, which may be destroyed by syringing with a solution of soft soap 2 ozs. to a gallon of water, adding to each gallon a pint and a half of tobacco juice. It is best applied in the evening of a dry calm day. The worst-infested shoots should be dipped in the solution.

GRASS IN STRAWBERRY BEDS (*P. H.*).—It is next to impossible to eradicate grass from the beds without seriously injuring the plants; and we can offer no better advice than to pull it out, which will destroy all the kinds except those that have creeping stems, and for these there is no remedy but to fork out the roots, and that would entail the destruction of the Strawberries. We should continue to pull up the grass. If it is Couch or any other grass with creeping underground stems, you may, by pulling them up as they appear, keep them in check; but the only effectual remedy will be to destroy the beds and thoroughly clear the ground of the roots by digging and forking these out. After cleaning, the ground would need trenching; and well manuring. See that the ground for the new beds is thoroughly cleared of the roots of the grass, and trenched and well manured.

CARELLIANS ON CAULIFLOWERS (*Idem*).—The best remedy is hand-picking, which you say you have practised without making much difference. Persist in it, and it will soon be found that the plants will be freed; or you may dust the plants with quicklime, choosing early in-morning, or just before dark in the evening.

ANNUALS FOR FLOWERING IN HOUSE (*Idem*).—You may sow now in pots the following annuals:—*Alyssum maritimum*, *Calandrinia umbellata*, *Campanula pentagona*, *Clarkia pulchella* var. *inarta* flore-pleno, *Collinsia bart-siefolia*, *C. bicolor*, *Eryimmum arkansanum*, *Enchardidium grandiflorum*, *Gilia tricolor*, *Gypsophila muralis*, *Kunzia amelloides*, *Leptosiphon densiflorus*, *Lupinus nanus*, *Mignonette*, *Neon phila insignis*, *N. atomaria*, *Platystemon californicus*, *Sap-naria calabrca*, *Silene pendula ruberrima*, *Venus's Looking-glass*, and *Virginian Stock*. They will need to have the protection of a frame in winter, or a position in-doors.

REMOVING OLD STEMS OF VINES (*Ten-years Subscriber*).—Cut away the old rods as soon as the Grapes are cut, or as early after this as you can. The manure on the border would not cause the Grapes to shank. Probably your crop is heavy, hence the want of colour; and the shanking may be due to the roots having gone deep into an outside border, and the roots not supplying sap to meet the demands of the branches.

VARIETIES OF VEGETABLES FOR EXHIBITION (*Idem*).—Of the varieties named in your list we select Marquis of Lorne Cucumber, Kidney Potatoes, Canadian Wonder Kidney Bean, Intermediate Carrot, Turnips, Nasby Mammoth Onion, Cauliflowers, Excel-sior Tomato, Mammoth Celery, and Custard Marrow. We should have liked you lot better if you had had Peas.

BLACKBERRY PLANTATION (*J. B. N.*).—We presume you refer to an answer to a correspondent in our number for December 5th, 1872. The address you require is Messrs. Rivers & Son, Sawbridgeworth.

VINE MILDEWED (*D. H.*).—It is very difficult to successfully combat mildew out of doors. Mix 8ozs. of soft soap and 8ozs. of flowers of sulphur in four gallons of boiling rain water, and thoroughly syringe the Vine with it. You should have some person stirring the water while you are using it. Every part affected must be wetted. If you fail to do this you will also fail to destroy the mildew. Many cures fail of the desired effect because they are not properly applied.

GRAPES ATTACKED BY BLISTER-BLE FLIES (*Subscriber*).—We have tried to protect our Grapes from these flies in many ways, but can only recommend one of them, and that is to hang gauze of some sort over the ventilators at the front and back of the house. It is of no use putting the bunches in bags, it will only spoil them.

PEAR LEAVES BLISTERED (*J. J.*).—We have seen leaves similarly affected when the roots were in a stiff, undrained clay soil. It is also caused by the sun acting upon the leaves after cold nights. If your trees are in unsuitable soil, dig round the roots and add turfy loam.

CELERY AND VEGETABLE MARROW CULTURE (*R. D. W.*).—Celery may be grown for many years upon the same ground if it is well manured after each crop. Remove the plants from the seed beds or pans as soon as they are large enough to handle, pricking them out 3 inches apart into a border of rich light soil, or a prepared bed of one half old leaf mould or rotten manure, and one half garden soil, with a little road grit or sand, well mixed. Water freely, and the plants will soon be ready for the trenches. Vegetable Marrows do well in any rich soil, or on a manure heap; in your case we should prefer the manure heap, or plant on a bed raised a foot or two above the common level, and you will have no more decayed plants. To obtain good Cucumber seed, impregnate the female flowers with the pollen of the male flowers, and let the fruit remain on the plant till it turns yellow. The seed, and all other of a similar character, should be kept dry, as damp spoils it.

CUCUMBERS YELLOW AT THE POINTS (*Another Gardener*).—We think you are killing your plant with kindness. The cause of the fruit turning yellow at the points is the atmosphere of the frame being too moist and the soil too wet. Do not give any water as long as the leaves do not flag, and we think you will have Cucumbers this month. We find in June frames that this year Cucumbers have required very little water, ours damping-off as yours

did; but we discontinued watering, admitted a little air at night, and watered only when the plants flagged. They have done well, a little shade being given from bright sun.

INSECTS ON GESNERAS AND GLOXINIAS (Cops).—There were some thrips on the leaves when they reached us. There was also an aphid. The atmosphere has been too dry and bright; slight shade from bright sun and a moister atmosphere would have been desirable, as the leaves are not only infested with insects, but slightly scorched, probably from the sun's rays falling powerfully on them whilst wet, or it may be due to the atmosphere being dry and the evaporation from the leaves excessive. For the insects fumigate the house on two successive evenings with tobacco, shutting the house up close, and wetting the floor and other surfaces, but keeping the foliage of the plants dry. These plants are easily injured in their foliage by strong fumigations, therefore only fumigate moderately.

VARIETIES OF STRAWBERRIES. L. C.—You should plant say nine sorts and select those most suitable for your garden. Black Prince is earliest, followed by Keen's Seedling, Sir J. Paxton, President, Premier, British Queen, Mr. Badelyffe, La Constante, and Pignore Late Pine.

USE OF SEWAGE (G. M. H.).—You will see what is said on our first page to-day. All your questions, and more, you will find answered in "Manures for the Man," which you can have free by post from our office if you enclose 3*d.* in stamp with your address.

NAMES OF FRUIT (H. B.).—Send the specimens carriage paid addressed to the Editors at our office, and we will name them. It must, however, be understood that we cannot undertake the labour of naming large hamperfuls at a time.

NAMES OF PLANTS (J. K. Hartlbury).—We cannot name varieties of florists' flowers, nor any plant from leaves only. (*Clara Subscriber*).—We cannot name plants from such scraps. (*Anne and Odors*).—We have received boxes, some without senders' names, and all with such numerous specimens that we could not examine them. (*C. F.*).—Your specimen is very imperfect; we believe it to be *Campanula trachelium*.

POULTRY, BEE, AND PIGEON CHRONICLE.

PUBLISHING JUDGES' NAMES.

I WAS rather glad to see this subject discussed again in the pages of the Journal, as I think it of some importance to the well-being of the fancy. I am not at present personally interested in the question either way, utter want of time preventing me from making any attempt to exhibit, except at the few great shows at the close of the year, at which, though we often do not know exactly who will judge our birds, we do know that competent parties are pretty sure to be appointed; but I have had various complaints poured into my ears of late concerning the awards at certain local exhibitions, which show things to be in a far from satisfactory condition. It is not perhaps very easy to take a beating good-temperedly, even when one is forced to acknowledge that the winning birds are really better than one's own; but when anyone who understands his breed knows and feels that his birds have been unjustly displaced in favour of birds which are not superior, it is only natural to expect that his feelings will be bitter indeed. Even then, if the mistake has been made by a sterling good judge, who has the sense to own it as a mistake which—perhaps from want of time, or bad light, or other reason—he could not avoid, and you know he has honestly done his best with the opportunities he had, you can, after the first momentary vexation, put up with the mishap; but when it is felt that such mistakes have been the result of sheer incompetence, directly chargeable to the committee of the show, I do not wonder that heart-burnings and dissatisfaction find open expression, as I know on many occasions lately to have been the case.

I wish, however, chiefly to point out two advantages which it seems to me would follow from the names of the judges being published in the schedule. The differences of opinion of certain judges are well known, and have been remarked upon already; for instance, I could name two who differ considerably as to what is the proper ground colour of a Gold-spangled Hamburg, and another, not deservedly respected, whose partiality to an almost bare leg in Asiatics, rather than to what most breeders now like—viz., a nice, full, but soft curling hack, is also notorious. I am not, be it remembered, finding fault with these gentlemen; my object is not at all personal, and they have as good a right to their own opinions as I have to mine, and to judge consistently with them. What I wish to point out is the obvious inconvenience and injustice to themselves which arises from the present system. Supposing, for instance, Mr. A has been winning at almost every show with his Cochins, so that it is well known he has about the best birds of the season, and such a judge as I have hinted at, dishing the "feather" of these birds, throws them out; the consequence is that the judge is branded as incompetent by men who know nothing of his breed, but only see that he passes by birds the usual judges consider standards. But most breeders of Asiatics have various kinds of leg feather in their yards, and had it been known that such and such a judge would be appointed, they could have selected a pen of birds, first-class in quality, of such a leg feather as would have suited him. The advantage would be not so much to Mr. A, but that the violent shock to public opinion would be avoided, and confidence in the judge maintained.

I cannot see that selecting pens to suit the views of judges is at all illegitimate. So long as they judge at all consistently, they have a right to do so by what they think correct standards, and also by discouraging measures to check any strong tendency they may think they perceive towards a given fault. There can be no harm in such consistent opinions becoming known, if only they are known alike and openly to all; and it is far worse as happens now, for a very few only to know who is going to judge, and thus have an advantage over the rest.

But what in my judgment would be a still greater benefit would follow. Committees, having to engage judges in time to put in their schedules, would be compelled to make early arrangements for judging; and even if disappointed of the man they first applied to, would still have ample time to engage some other competent person. As it is, they perhaps leave it till only a week or two before the show, and then write off in a hurry to, say, Mr. Hewitt. He is engaged. Then they apply to Mr. Teebay. He is engaged too. They try someone else; and at last are obliged to be content with someone who would never have been even thought of, had it not been left till too late to get anyone else. And not only so, but many clashing dates would thus be prevented. For suppose a committee write to a well-known judge and ask him if they may count upon him to judge at A—, on the 15th November. He writes back, perhaps, "I would gladly come, but I am engaged to judge at B— on the same day." The question at once arises (the schedule not being yet issued), whether the A— committee had not better alter their date to avoid clashing with B—, and thus they very likely would avoid an injurious competition, and get their wished-for judge after all.

I have never seen one good argument against such a course. If a judge is at all accessible to private letters, supposing him known beforehand, he lacks the very first element of the judicial office—integrity, and the sooner he is disposed the better. Should he be troubled with any kind of letters, he may justifiably leave them unanswered if he chooses. In simple fact, there are dozens of shows yearly, which it is well understood will be judged by the same parties yearly if nothing absolutely prevents; and I am quite sure these shows and the judges who officiate there stand at least as far above suspicion as any others whose judges are not known.

I hope the correspondence will draw out a few more opinions upon the subject. I do not mean necessarily all on one side. If there are any good reasons why the names should not be published, I am sure we should all like to hear them, and that exhibitors as a body are open to conviction.—L. WRIGHT.

EXHIBITION FRAUDS.

TWO letters have recently appeared in your Journal strongly condemning the practice of persons exhibiting what they have "bought," and Mr. Paul in effect states that no one should be allowed to exhibit plants, flowers, or such-like unless they were actually "cultivated," and brought to their true state of excellence by the "skill and industry" of the exhibitor; but if this rule were made law it would practically put a stop to all shows of whatever sort or kind. A rule that applied to an exhibition of the vegetable kingdom must, by a party of reasoning, apply to an exhibition of the animal kingdom; and therefore if a person who exhibits flowers he has bought is to be considered as wanting in morality, and guilty of a fraud, and to be held up to general execration, so also must be he who buys "a pretaking animal" at one show and exhibits it afterwards at others as his own, and yet this is the rule rather than the exception. The great majority of the horses, dogs, poultry, &c., exhibited at our present shows, were never bred nor reared by the exhibitors, but simply purchased, or perhaps even only borrowed for the occasion. "Skill and industry" have had nothing to do with the matter; it has been merely a question of pounds, shillings, and pence; and therefore if an exhibitor is considered perfectly justified by all rules and precedents in exhibiting and taking a prize at a show with some animal which he has just purchased, why should an exhibitor be so severely condemned for doing exactly the same thing with plants, flowers, &c.? If the prize were for "the best roses to be grown by the exhibitor," "bought roses" would be of course disqualified, and in a country show everybody would know whether they were bought or not; but if simply for "the best roses," no one could be considered guilty of fraud because he himself had not grown what he exhibited.—L. C. C.

POULTRY ON AMERICAN FARMS.

THE careful manager of a full stock of all the varieties comprised in a respectable establishment, will be particular to place the Turkeys so that they cannot worry the common hens; the Geese so that they will not tyrannise over the Ducks, and so on with the rest, at the same time preventing the breeding portion from being annoyed by their own species; for the young broods do best when away from the regular haunts of the old fowls.

At the present moment I know of two places where poultry

have been raised and are being raised. They are within sight of each other. The first started with eighty common hens, six Turkey hens, six Guinea hens, six Muscovy Ducks, and forty pairs of old Pigeons. The management at this place was about as follows:—The women walked around every morning and evening calling "Biddy! Biddy! chick! chick!" throwing first corn and then wetted meal, never looking to the right or left to see whether old hens, Turkeys, or Guinea fowls ate up the food; and the broods of young chickens got next to none. The eggs were looked up two or three times a week, and sometimes not so often; every species laid, and were set in hay-mows, mangers, &c., and commenced sitting on about thirteen eggs; but others would be laid to them till twenty would be there, and some would be put under other hens. The result of this has been about three dozen eggs per week, besides what have been broken and spoiled by the general casualties attending the situation; about eighty chickens from at least fifty sitting hens, two or three hatchlings making up a brood; eight young Turkeys from the six old hens, and Guinea birds, &c., in proportion. The Pigeons do the best, yet the eighty old Pigeons have only about twenty nests, and those and the floor of their room is 3 inches or more thick with dried dung; and the floor of the room has as many nests as the Pigeons can agree upon. In other buildings, those not likely to fight for a place in the crowded cote, find corners, &c., and bring forth young, giving a better return than the other feathered creatures.

The second place alluded to is a long way from being perfect, as the premises are not so convenient, there being no farm buildings, and consequently no shelter beyond where the fowls roost. This place had nearly as many common fowls, three Turkey hens, and twelve Ducks. These had nests made chiefly by placing old flour barrels about, and the young chickens were fed every two or three hours, from sunrise till they went to rest; eggs looked up every day; sitting hens' eggs all marked, and every one looked under each day; fowls never called, but old ones fed morning and evening, always at one time. Results not so good as might have been, as a fox took over forty, vermin and hawks more than that number, and a heavy thunderstorm drowned several Turkeys, &c. However, 320 chickens survive, or have been used for the table; thirty-seven young Turkeys and 102 Ducks; the eggs having averaged over ten dozen per week—fifteen dozen some weeks; the chickens sold made \$5 and \$6 per dozen, and the eggs twenty cents and upwards per dozen (forty cents at the start). The food consumed has been about the same at both places, the Pigeons being great eaters—from one and a half to two bushels of corn per week at each place. The range is unlimited at either place.—A WORKING FARMER.—(Rural New-Yorker.)

WHITBY POULTRY SHOW.

The fortieth annual gathering of the Whitby Agricultural Society was held on the 27th of August, and the day being fine the number of visitors was very large. The poultry pens were placed in single tier along two sides of the field.

Adult *Dorkings* were first on the list, and they were good, but the chickens of that variety were even better, the whole of both lots being of the Dark Grey variety. *Spanish* were a fair lot, but somewhat low in condition. Both adult and young *Cochins* were extremely good. Among the former a grand pair of Whites was first, closely pressed by a very large pen of Buffs. Buffs also won in the chickens. In adult *Brahmas* the winners were Dark, but a pen of Light birds fairly left all the Dark ones in the next class. *Game* do not require special notice. *Hamburghs* had six classes devoted to them, but the entries were few, though the winners in most cases left little to be desired. In the Gold-spangled class the competition was very close, the second losing only by a slight loss of colour on the bottom of the tail. The cup for the best pen in the Show was awarded to a pen of Silver-pencilled in the adult class, and these birds were in splendid bloom and perfect in all particulars. For *Game Bantams* the first prize was gained by Piles, and the second by Black Red chickens; and in the following class Black Rose-combed were first, and White second. In the Any other variety class Gold Polands were first, and Crève-Cœur second.

Aylesbury Ducks were well shown and good in all respects, and some of the birds were claimed at a very low rate. *Rouens* were also good but out of feather, especially in the adult class. The first-prize *Geese* were large White birds in the best possible trim, and the second were Toulouse of good quality.

The *Pigeon* prizes were small, and the birds not numerous, but there were some good birds, the first-prize White Pouters being a fine showy pair. Carriers were poor, but both Fantails and Jacobins contained some good specimens; the only other pair of great merit was of Spangled Ice Pigeons in the Variety class.

- DORRINGS.—1, J. White. 2, R. Smith, jun., Norton, Malton. *he*, Lady D. Woodthorpe, Whitby. *c*, A. Jackson, Great Broughton. *Chickens*—1, J. White, Warburton. 2, E. Barker, Stokesley. *he* and District Cup, J. Carr, Whitby. *he*, J. Watts, Barmotham.
SPANISH.—1, J. Powell, Bradford. 2, H. Beldon, Bingley. *c*, J. Booth, Lythe. *Chickens*—1, H. Beldon.

- COCHINS-CHINA.—1 and *phe*, G. H. Frocter, Darham. 2, H. Beldon. *c*, F. Horseman, Boroughbridge; H. Tomlinson, Birmingham; G. Holmes, Driffield. *Chickens*—1, G. H. Frocter. 2, H. Tomlinson, *he*, H. Beldon; D. & I. Betson, Whitby.
BRAHMA POOTRA.—1, J. F. Smith, Sheffield. 2, H. Beldon. *he*, F. Horseman. *Chickens*—1, H. Beldon. 2, J. Booth. *he*, W. Whiteley, Sheffield.
GAME.—*Black-boned* and *other Reds*—1, H. Beldon. 2, H. M. Julian, Hull. *c*, W. Wharton, Scarborough. *Any other variety*—1, H. M. Julian. *Chickens*—1, J. T. E. Statterthwaite, Castle Howard. 2, T. Pyson, Halifax. *c*, T. Peirson, Rosedale, Pickering.
HAMBURGH.—*Gold-spangled*—1, G. Holmes. 2, J. Rollinson, Lindley. *he*, H. Beldon; J. Rollinson. *Silver-spangled*—1, H. Beldon. 2, J. Rollinson. *he*, W. Dickson, Lythe; T. Tweedy, Thrusk. *Golden-pencilled*—1, H. Beldon. 2, T. H. Readman, Whitby. *he*, G. Holmes. *Silver-pencilled*—1 and Cup, H. Beldon. 2, G. Speedy. *he*, T. H. Readman.
HAMBURGH.—*Gold* or *Silver-spangled*—*Chickens*—1, H. Beldon. 2, G. Speedy. *Gold* or *Silver-pencilled*—*Chickens*—1, H. Beldon. 2, W. E. Clayton, Kettleby. *he*, D. Waller, Stokesley. *c*, J. Webster.
BANTAMS.—*Game*—1, G. Holmes. 2 and *he*, W. C. Dawson. *Any other variety*—1 and 2, H. Beldon. *he*, J. Watts. *c*, R. Henderson, Middlesborough; J. Russell, Whitby.
ANY OTHER VARIETY—1 and *phe*, H. Beldon. 2, T. P. Carver, Langthorpe, Boroughbridge. *he*, Mrs. Cooper. *c*, T. Peirson; W. J. Weverhill, Whitby; R. Ward, Whitby.
FARMYARD CROSS.—1, R. Smith, jun., 2, J. Ireland, Frodingham. *he*, J. Storry, Stokesley; G. Pounder, Kirby Moorside.
SELLING CLASS.—*Cock* and *Hen* or *Drake* and *Duck*—1, G. Urwin, Whitby (Buff Cochins). 2, E. Barker (Dorkings). 3, R. Smith, jun. *he*, T. P. Carver; J. Bassell (Silver-spangled Hamburghs). *c*, T. P. Carver; T. Dobson (Brahmas); Mrs. Stonehouse, Darhulm (Spanish).
DISTRICT CUP.—*Black-boned*, *Spanish*, *Cochins*, *Brakins*, or *French*—*Chickens*. 1, J. Carr. *Game*, *Hamburgh*, or *Bantam*—*Chickens*—1 and Local Cup, G. Speedy, Whitby. 2, J. Webster, Whitby. *he*, T. H. Readman; G. Speedy. *c*, J. Russell.
DUCKS.—*Aylesbury*—1, T. P. Carver. 2, Mrs. Stonehouse. *Ducklings*—1, T. Scar, Tingwick. 2, J. W. Storry. *he*, T. P. Carver. *c*, O. A. Young, Driffield. *Rouen*—1, G. Garbit, Sunnington. 2, T. M. Derry, Gedney, Wisbeach. *he*, Mrs. Welford, Roxby. *Ducklings*—1, Miss Jordan, Driffield. 2, G. Sadler, Boroughbridge. *Any other variety*—1, J. Watts. 2, G. Sadler. *he*, R. P. Clarkson, Farmyard Cross—1, Mrs. Welford.
GESE.—1, J. W. Storry. 2, O. A. Young. *he*, P. Bedlington, Whitby. *c*, W. Thompson, Lealholm. *Swans*—1.—Hudson, Malton. 2, W. Thompson. *c*, R. P. Clarkson.
TURKEYS.—1, T. P. Carver. 2, Mrs. W. Ward. *Poult*s—1 and 2, Mrs. W. Ward. *he*, J. Storry.
EXTRA STOCK.—1, M. Simpson, Whitby (Silver Pheasant).
PIGEONS.
POTTERS.—1, J. Blanchard, Great Driffield. 2, J. E. Crofts, Blyth, Workop. *he*, J. Kilpatrick, Whitby. *c*, T. Booth, Lythe.
TUMBLERS.—1, H. Yardley, Birmingham. 2, G. Pyman, Raithwaite. *c*, J. Acouley, Rosedale Abbey.
CARRIERS.—1, J. E. Crofts. 2, J. Acouley. *he*, G. Sadler.
FANTAILS.—1, J. F. Loversidge, 2, G. Pyman.
JACOBINS.—1, R. G. Sanders, Leven, Beverley. 2, S. & T. Denham, Pickering. *he*, J. Acouley; J. E. Crofts. *c*, H. Yardley.
TRUMPETERS.—1, J. E. Crofts. 2, J. H. Watkins, Hereford.
BARBS.—1, H. Yardley. 2, J. P. Fawcett, Whitby. *c*, J. E. Crofts.
ANY OTHER VARIETY.—1, J. E. Crofts. 2, J. H. Watkins. 3, J. Kilpatrick. *he*, J. Pyman; G. Sadler; J. Acouley (2); H. Yardley; J. Watts; T. Booth. *c*, J. E. Crofts; J. W. Hyde, Norton, Malton.
SELLING CLASS.—1, J. E. Crofts. 2, S. & T. Denham.
The Judge was Mr. E. Hutton, Pudsey.

CIRENCESTER POULTRY SHOW.

This was held in the Abbey Grounds on the 28th of August. The awards were:—

- DORKINGS.—1, Rev. E. Bartram, Berkhamstead. 2, S. Probert, Lostwithiel. *he*, T. C. Burnell, Mitcheliever. *c*, J. Watts, King's Heath.
SPANISH.—1, H. Feast. 2, E. W. Darby, Cirencester.
GAME.—*Black-boned* and *other Reds*—1, E. Winwood, Worcester. 2, G. S. Prentice, Ampney Crucis. *c*, E. S. Goodell, Stroud; J. Smith, Chesterton. *Any other variety*—1, E. Aykroyd, Whitehill. 2, E. Winwood.
BRAHMAS.—*Light*—1, E. Woodworth, Cheltenham. 2, Rev. N. J. Ridley, Newbury. *he*, J. Mitchell, Mosley. *c*, J. Hope, Fairford; T. A. Dean, Malden. *Dark*—1, Cup, and *c*, T. F. Ansdell, St. Helen's. *he*, H. Feast; J. Trinder, Cirencester.
BRAHMAS.—*Light* or *Dark*—*Chickens*—1, T. F. Ansdell. 2, W. Ford, Hamberstone. *he*, A. Gibson, Woodley; O. E. Cresswell, Bagshot; J. Turner, Bath; T. A. Dean, Malden. *c*, H. Feast. 2, E. Knorr, Bristol; W. Morris, Ross.
COCHINS.—*Light*—1, S. Probert. 2, R. S. Woodgate, Pembury. *he*, J. Bloodworth, Cheltenham. *Any other variety*—1, Mrs. Ainsop, Worcester. 2, T. F. Ansdell. *he*, H. Feast. *c*, E. Bloodworth.
HAMBURGH.—*Gold* or *Silver-spangled*—1, Mrs. G. M. Rolfs, The Hendre. 2, H. Feast. *c*, J. S. Maggs, Tetbury. *Gold* or *Silver-pencilled*—1, C. Bloodworth. 2, J. McConnell, Ewyas Harold. *he*, H. Feast.
FRENCH.—1, Rev. N. J. Ridley. 2, H. Feast.
GAME BANTAMS.—*Black* or *Brown Reds*—1, A. Ashley, Worcester. 2, E. Bony, Southampton. *c*, E. Bowly (2); R. Scammell, Hupperton; G. S. Prentice. *Any other variety*—1, J. Mayo, Gloucester. 2, A. Ashley. *he*, R. Smith, Cirencester. *c*, C. Simpson, Ampney Crucis.
SELLING CLASS.—1, Miss J. Milward, Newton St. Loe. 2, J. Croote, Heavittree. 3, H. Feast.
ANY OTHER VARIETY.—1, J. Croote. 2, C. Bloodworth. *c*, H. Feast; S. Probert, Lostwithiel. *Chickens*—1, Rev. R. W. Everett, Monmouth. 2, H. Feast. *he*, E. S. Goodell, Stroud; M. H. Sturt, Pewsey; C. Bloodworth (2); T. T. Cooper, Malwood; Viscountess Abingdon; F. F. Fowler, Plymouth. *c*, J. Watts; J. Turner; M. H. Sturt (2); J. S. Backland, Cradwell.
DUCKS.—*Rouen*—1, E. Ponting, Rodden Down. 2, G. Holloway, jun., Stroud. *he*, G. Key, Coates. *Aylesbury*—1, E. Bowly, Saldington. 2, J. S. Maggs. *he*, J. S. Maggs, Tetbury; H. Feast. *c*, G. Key, Coates; T. A. Dean. *Any other variety*—1 and 2, G. S. Sainsbury, Dizes. *c*, R. S. S. Woodgate, Pembury.
GESE.—1 and 2, A. M. Murphy, Cirencester.
TURKEYS.—1, Rev. N. J. Ridley, Newbury. 2, T. Porter, Baunton. *he* and *c*, W. Slater, Stratton.
FRASANT OR GUINEA FOWL.—1, L. D. Little. *he*, J. Cross, Rendcombe. *c*, D. Blackford, Cirencester. 1, L. D. Little, Driffield; W. Slater.
SWEETSTAKES.
BRAHMA.—*Light* or *Dark*—*Cock*—1 and Extra, T. F. Ansdell. 2, J. Turner. *GAME BANTAM*—*Cock*—1, E. Bowly. 2, A. Ashley, Worcester. 3, J. Habgood, Stratton.
PIGEONS.
CARRIERS.—1, P. B. Spencer, Hereford. 2, H. Yardley, Birmingham.
DRAGONS.—*Blue* or *Silver*—1, H. Yardley. 2, N. Cuss, Ampney Crucis. *c*, W. Lane, Hereford.
FANTAILS.—1, Miss J. Milward, Newton St. Loe. 2, H. Yardley. *c*, F. J. Lovridge, Newark.

ANTWERPS.—1, D. Blackford. 2, H. Yardley. *hc*, F. B. Bulley, Oxford; J. Croule (2).
 JACOBINS.—1, O. E. Cresswell, Bazshot. 2, J. Croule.
 OWLS.—1, E. Lee, Nantwich. 2, G. S. Prentice. *hc*, J. Croule; H. Yardley.
 TUMBLERS.—1, *any variety except Almonds*.—1, J. Croule. 2, H. Yardley.
 ANY OTHER VARIETY.—1, H. Yardley. 2, H. Stanley, Stroud. 1, Essex 2, P. R. Spencer, Hereford. *hc*, K. Barrett, Stroud; O. E. Cresswell; F. B. Bulley, Oxford (2). *c*, G. Holloway, jun.; J. Croule.
 SELLING CLASS.—1, E. F. Woodman, Cirencester. 2, P. R. Spencer. *c*, G. H. Gregory, Taunton; G. Holloway, jun.; J. Croule; T. A. Dean.
 JUDGE.—Mr. W. B. Tegetmeier, of London.

HALIFAX AND CALDER VALE POULTRY SHOW.

The meeting of the Halifax and Calder Vale Association was held on August 30th. This, one of the oldest of the Yorkshire agricultural societies, is very popular in the West Riding and Lancashire, and the day being fine there was an immense gathering of visitors. The management and arrangements were perfect, with the exception that the poultry and Pigeon pens were open both back and front, causing a draught not at all suitable for the birds, but we understand pens of a more modern type will be adopted in future. As is generally the case at the end of the season, the entries in both poultry and Pigeons were not large, but the quality was very high, especially in the case of the Pigeons, of which few birds were shown except by celebrated exhibitors.

We were surprised to find the adult poultry in such good plumage, some of them scarcely showing signs of moult, while, taken as a whole, the young birds were not so forward as we usually find at this time of year.

The class for adult *Spanish* was very good, and the cup for the best pen in the Show was awarded to the first-prize bird. Adult *Dorkings* were few but of fair quality, as were also the chickens. *Cochins* and *Brahmas* were well represented, and the *Game* classes good, which may be explained by the great encouragement offered to that variety. *Polish* were very good in both classes, and *Golden* won the first prize in each case. *Hamburgs* were good in all the classes, although some of them seemed to be rather overshadowed. There were no good *Game Bantams* with the exception of about two pens, but several of the Blacks were of fair quality, and the Variety class contained good birds throughout. The first prize went to Pekins, and the second to Silver Sebrights.

Aquatic birds were well represented in all classes, and the first-prize *Turkeys* were very large.

In the Selling class White *Cochins* were first, and Light *Brahmas* second.

Pigeons, as before stated, were of the highest quality, but in some classes the birds were out of feather and showed signs of fatigue. The whole of the birds in the first three classes were named, the first prize in *Pouter* cocks going to a handsome *Blue* in capital show, though not so long a bird as the second, which was a *White* one extremely neat but not in full blow. In *Hens*, a very large and perfect *White* was first, and this also won the cup for the best pen in the Show; it was in the highest possible show condition. In *Carrier* cocks the first prize went to a *Black*, and the second to a *Dun*; but the gem of the *Carrier* classes was the *Black hen* shown by Mr. Fulton. *Almonds* were a neat lot, and the competition close. The first prize went to the smallest and best-matched pair we have ever seen in the show-pen, the second being very high in head properties, but the cock somewhat dark. In *Tumblers* of any other kind the winners were both *Black Mottles*, *Kites* and *Splashes* being highly commended. The winning *Dragoons* were *Blue* and very good, but most of the others too flat in the skull. *Trumpeters* were all noticed and mostly of the foreign variety, the first prize going to an extraordinary pair of *Black Mottles*, and the second to *Blacks*. *Owls* were all foreign, but some of the best were out of feather, the winners being *Whites*. The winning *Turbits* were *Blue*, but with one exception the rest were not noteworthy. *Jacobins* for the most part were a little soiled, but the birds noticed were very good, the winners being *Red* and the highly commended birds *Yellow* and *Black*. The first-prize *Fantails* were an extraordinary pair, the tails being of immense size. In *Barbs* *Blacks* were first, and *Duns* second, and in head properties they were an extraordinary lot, but very few were in good condition. *Antwerps* were bad, scarcely one really good bird being shown. In the Variety class, Spangled *Swallows* were first and *Nuns* second, while a nice pair of plain-backed *Ice Pigeons* were highly commended.

There was a good display of eggs, the two winning dishes being large but not so sound in shell as some of the smaller lots; the latter point is of the utmost importance for success.

SPANISH.—1 and Cup, J. Leeming, Broughton, Preston. 2, J. Powell, Bradford. *hc*, H. Wilkinson, Early, Skipton; H. Beldon, Goutstock, Bingley. *Chickens*.—1, J. Leeming. 2, H. Beldon.
 DORKINGS.—1, J. Walker, Rochdale. 2, J. Robinson. *Chickens*.—1, T. Statter, Manchester. 2, J. R. Johnson.
 COCHINS.—1, C. W. Brierley, Middleton. 2, H. Beldon. *Chickens*.—1 and *hc*, A. Sedgwick, Keighley. 2, H. Beldon.
 BRAHMA POUCE.—1, B. Bowness, Newchurch. 2, H. Beldon. *hc*, A. H. Haigh, Lindley. *Chickens*.—1, J. H. Pickles, Birkdale, Southport. 2, H. Beldon. *hc*, J. H. Pickles. *c*, Carr, Walsden, Bingley; W. Whiteley.
 GAME.—*Black-headed Red*.—1, J. Fletcher, Stoneclough, Manchester. 2, T.

Bottonley, Shelf. *hc*, H. Beldon. *c*, R. Hemmings, Shelf. *Chickens*.—1, J. Fletcher. 2, Travis & Barton, Thurgoland, Sheffield.
 GAME.—*Brown-breasted and other Reds*.—1, C. W. Brierley. 2, J. Fletcher. *Chickens*.—1 and 2, W. T. Coates, Barnoldswick, Leeds. *hc*, W. Ormerod, Walsden, Burnham, *c*, J. Forth, Keighley.
 GAME.—*Duckwing Grey or Blue*.—1, J. Fletcher. 2, E. Aykroyd, Eccleshall. *Chickens*.—1, Travis & Barton. 2, J. Fletcher.
 GAME.—*Any variety*.—1 and 2, R. Walker, Gomersal. *Chickens*.—1, H. C. and W. J. Mason, Drighlington.
 POLANDS.—1 and 2, H. Beldon. *Chickens*.—1, J. Robinson, Garstang. 2, H. Beldon.
 HAMBURGS.—*Gold or Silver-spangled*.—1, H. Beldon. 2, J. Bowness, Newchurch. *hc*, J. Robinson. *Chickens*.—1, W. & E. Clayton, Rothley. 2, J. Robinson. *hc*, J. Robinson; J. Bowness.
 HAMBURGS.—*Gold or Silver-spangled*.—1, J. Robinson. 2, J. Robinson. *hc*, J. Robinson; H. Beldon. *Chickens*.—1 and *hc*, J. Robinson. 2, J. Robinson.
 HAMBURGS.—*Any other variety*.—1, H. Beldon. 2, J. Bowness. *hc*, J. Robinson. *Chickens*.—1, F. W. Hobbes, Rasheroff, Baildon. 2, J. Robinson. *hc*, J. Bowness.
 ANY OTHER VARIETY EXCEPT BANTAMS.—1, J. Robinson. *Chickens*.—1, C. J. Holloway, Bingley.
 GAME BANTAMS.—1, J. Noble, Staincliffe. 2, W. F. Adhe, Preston. *hc*, W. F. Adhe; F. Steel, Halifax.
 BANTAMS.—*Black*.—1, H. Beldon. 2, E. Walton, Horncliffe. *hc*, J. Walker. *Any other variety*.—1, H. B. Smith, Brooklands, Broughton. 2, E. Walton. *hc*, H. Beldon.
 DUCKS.—*Julesburg*.—1 and 2, J. Walker. *hc*, R. Hutchinson, Littleborough. *hen*.—1, J. Newton, Harwood, Leeds; W. Harvey, Shelfield; K. Fulton; J. Hawley, Gillington, Bradford; J. G. Taylor, Huddersfield. *Hen*.—1 and Cup, W. Harvey. 2, R. Fulton. *c*, R. Holloway, Halifax; T. Rule; E. Horner; W. Harvey; K. Fulton; J. Hawley; J. G. Taylor.
 CARRIER.—*Cock*.—1, J. G. Taylor. 2, E. Horner. *c*, H. Yardley; R. Fulton (2). *Hen*.—1 and 2, R. Fulton. *c*, E. Horner (2).
 TUMBLERS.—*Almond*.—1, R. Fulton. 2, J. G. Taylor. *c*, E. Horner; H. Adams, Bowley; W. Harvey; H. Yardley, Birmingham; R. Fulton; J. Fielding, jun.; Rochdale. *Any other variety*.—1, J. Fielding, jun. 2, R. Fulton. *hc*, J. G. Taylor; E. Horner; H. Yardley. *c*, W. Harvey.
 DRAGOONS.—1, W. Harvey. 2, H. Yardley. *hc*, E. Horner; E. Burnhill, Cleckheaton; R. Fulton (2).
 TRUMPETERS.—1, T. Rule. 2, R. Fulton. *hc*, E. Horner.
 OWLS.—1, J. G. Taylor. 2, H. Yardley. *hc*, E. Horner; J. Fielding, jun. (2).
 TURBITS.—1, R. Fulton. 2, J. Fielding, jun. *hc*, T. Foster (2).
 JACOBINS.—1, R. Fulton. 2, E. Rule. *hc*, J. Hawley; J. G. Taylor.
 FANTAILS.—1, T. Rule. 2, E. Horner.
 BARBS.—1, E. Horner. 2, J. G. Taylor. *hc*, R. Fulton (2); J. Fielding, jun.
 ANTWERPS.—1, T. Foster. 2, J. Hawley. *hc*, E. Horner; H. Yardley.
 ANY OTHER VARIETY.—1, J. G. Taylor. 2, E. Horner. *hc*, J. Thresh; H. Yardley; R. Fulton.
 SELLING CLASS.—1, J. Hawley. 2, E. Horner. *c*, J. F. Loversidge.
 The Judges were—for Poultry, Mr. Teelay, Preston; for Pigeons, Mr. E. Hutton, Pudsey.

BURY POULTRY SHOW.

The third annual Exhibition of the Bury Agricultural Society was held at Fishpool, Bury, on the 25th of August.

In the poultry department, *Spanish* adults headed the list; some good specimens competed, but nearly all were sadly out of condition. *Brahmas*, *Cochins*, and *Dorkings* were all good classes. The *Game* were not numerous, but choice, more particularly the *Brown Reds*. Some of the chickens of the same colour were very promising. *Hamburgs*, as usual in this part of the country, were excellent, the first-prize *Gold-spangled* adults deserving especial mention. All the chicken classes contained capital birds, with a very close competition. *Game Bantams* were not largely shown; all the prize pens, however, made up for this deficiency by their quality. *Black* and *White Bantams* had each a separate class, with a capital entry. In the class for *Any other variety of Bantams*, *Pekins* were first, and *Silver-laced* second. *Creve-Coeurs* took the prizes in adults, *Any other variety*; *Houdans* and *Malays* in chickens.

The *Turkeys*, *Geese*, and *Ducks* were very good, the Rouen *Ducks* being particularly so, almost every pen receiving notice, and all being worthy of a prize. The *Pigeons*, although not numerous, formed a very nice collection, nearly all varieties being fairly represented.

The following is the prize list:—

SPANISH.—1, H. Wilkinson, Early, Skipton. 2, Furness & Snell, Rawton-stall. *hc*, J. Thresh; J. Nash, Walsall. *Chickens*.—1, H. Wilkinson.
 COCHINS.—*Cinnamon or Red*.—1 and 2, W. A. Taylor, Manchester. *Chickens*.—1, W. A. Taylor. 2, C. Sedgwick, Keighley. *hc*, C. Sedgwick; H. Tomlinson, Birmingham.
 COCHINS.—*Any other variety*.—1, C. W. Brierley, Middleton. 2, W. Hey, Rochdale. *hc*, W. A. Taylor. *Chickens*.—1, W. A. Taylor. 2, C. Sedgwick. *hc*, W. A. Taylor; E. S. S. Woodgate, Pembury, Tunbridge Wells.
 BRAHMAS.—*Dark*.—1 and 2, T. F. Ansell, Covey Mount, St. Helens. *Chickens*.—1 and 2, J. H. Pickles, Southport. *hc*, C. Leyland, Warrington; W. A. Taylor.
 BRAHMAS.—*Light*.—1, H. Beldon, Bingley. 2, S. A. Smith, Withington. *Chickens*.—1, H. Beldon. 2, T. A. Dean, Marden, Hereford. *hc*, J. Watts, Birmingham.
 GAME.—*Any colour*.—*Cock*.—1 and 2, C. W. Brierley.
 GAME.—*Black or Brown Red*.—1 and 2, C. W. Brierley. *Chickens*.—1, W. Tiltotson, Coates, Leeds. 2, E. Mann, Wallbild Stand, *hc*, W. Tiltotson. *hc*, J. R. Fletcher; E. Mann; T. P. Lyon, Liverpool; W. Ferrin, Southill.
 GAME.—*Any other variety*.—1, C. W. Brierley. 2, Furness & Snell. *hc*, J. Answorth. *Chickens*.—1, C. W. Brierley. 2, Furness & Snell. *hc*, J. R. Fletcher.
 GAME.—*In bloom and feather*.—*Cock*.—1, J. R. Fletcher, Stoneclough, Manchester. 2, T. Tomlinson, Bury.
 POLARDS.—1 and 2, H. Beldon. *hc*, J. Robinson, Garstang. *Chickens*.—1, J. F. Lawson, Newton-le-Willows. 2, J. Robinson.
 HAMBURGS.—*Golden-spangled*.—1, G. & J. Duckworth, Chelch. 2, J. Bow

ness, Newchurch. *hc*, H. Beldon; J. Robinson. *Chickens*.—1, J. Robinson. 2, J. Hall, Stacksteads. *hc*, G. & J. Duckworth.
HAMBURGHS.—*Silver spangled*.—1 and 2, J. Robinson. *hc*, H. Beldon. *Chickens*.—1, M. Isherwood, Bury. 2, J. Robinson. *hc*, H. Beldon; H. Stauworth, Worsthorpe, Bury.
HAMBURGHS.—*Golden-pencilled*.—1, H. Beldon. 2, J. Bowness. *Chickens*.—1 and 2, W. & E. Clayton, Morton Banks, Keighley. *hc*, G. & J. Duckworth; J. Bowness.
HAMBURGHS.—*Silver-pencilled*.—1, J. Bowness. 2, H. Beldon. *hc*, J. Robinson. *Chickens*.—1, J. Robinson. 2, H. Smith, Keshley. *hc*, H. Beldon.
HAMBURGHS.—*Black*.—1, J. Robinson. 2, H. Beldon. *hc*, N. Marlor, Denton, Manchester; W. A. Taylor; J. Bowness. *Chickens*.—1, N. Marlor. 2, M. Isherwood. *hc*, C. Sidgwick; H. Beldon; W. A. Taylor; J. Bowness.
DORKINGS.—1, J. Robinson. 2, J. Walker, Rochdale. *hc*, A. Darby, jun., Bridworth. *Chickens*.—1 and 2, T. Statter, Stand, Manchester. *hc*, J. Stott, Healey, Rochdale.
ANY OTHER VARIETY EXCEPT BANTAMS.—1, J. Robinson. 2, G. W. Hibbert, Hyde, Manchester. *Chickens*.—1, G. W. Hibbert. 2, J. F. Walton, Horncleafe, Rawtenstall.
BANTAMS.—*Game*.—*Black or Brown*.—1 and 2, W. F. Entwisle, Westfield, Bradford. *hc*, T. Bowker, Hill End, Bury. *Any other variety*.—1, E. Walton. 2 and *hc*, W. F. Entwisle. *Any other variety except Game*.—1, H. B. Smith, Brooklands, Preston. 2, E. Walton.
GAME.—*Cock*.—1 and 2, W. F. Entwisle.
GAME.—*White*.—1, I. Cropper, Beap. 2, H. Beldon. *hc*, T. Cropper, Pickles and Whittaker, Great Hey, Edenfield; E. Walton. *Black*.—1, E. Walton. 2, W. A. Taylor. *hc*, Pickles & Whittaker; H. Beldon; R. H. Ashton, Mottram, Manchester.
DUCKS.—*Aylesbury*.—1 and 2, J. Walker, Spring Mount, Rochdale. *hc*, R. Hatchinson, Shaw Moss, Littleborough; T. Tomlinson, Elton. *Ruon*.—1, T. Wakefield, Gholme, Newton-le-Willough. 2, T. Statter. *hc*, J. Walker, P. Unsworth, Newton-le-Willows; T. Wakefield; T. Statter. *Any other variety*.—1 and *hc*, H. B. Smith, Brooklands, Preston. 2, J. Walker.
GEES.—*White*.—1 and *hc*, J. Walker. 2, T. Statter. *Goslings*.—1, J. Walker. 2, T. Statter. *Grey*.—1, T. Statter. 2, J. Walker. *Goslings*.—1 and 2, J. Walker. *TURKEYS*.—1 and 2, J. Walker. *hc*, Mrs. Milnes, Oaklands, Walmsley. *Chickens*.—1, Mrs. Milnes. 2, J. Walker.

PIGEONS.

POUTERS.—1, T. Rule, Gilesgate, Durham.
CARRIERS.—1, J. Chadwick, Lark View, Bolton.
TUMBLERS.—*Amoud*.—1, J. Fielding, jun., Rochdale. 2, J. J. Stott, Preston. *Bulls or Beards*.—1 and 2, J. Fielding, jun. *hc*, W. Hill, Heaton Moor. *Any other variety*.—1 and 2, J. Fielding.
OWLS.—*Foreign*.—1 and 2, J. Fielding. *English*.—1, J. Chadwick, Bolton. 2, A. Jackson, Chequerbent, Bolton. *hc*, J. Whitworth, Bury; R. Erierley, Fish-pool, Bury.
BARBS.—1, A. Justice, Salford. 2, J. Fielding, jun. *hc*, H. Yardley, Birmingham.
TURBITS.—1 and 2, J. Fielding. *hc*, J. B. Bowden, Blackburn.
NUSS.—1, J. W. G. Birmingham. 2, J. B. Bowden. *hc*, T. A. Dean, Marton.
JACOBS.—1, W. Dugdale, jun., Ennley. 2, T. Rule, Gilesgate, Durham. *hc*, W. Hill, Heaton Moor.
ANTWERPS.—1, A. Justice. 2, W. Gamon, Chester. *hc*, R. Erierley, Bury J. Wright, Manchester.
FANTAILS.—1, H. O. Bowman, Higher Broughton. 2, W. Hill.
DRAGOONS.—1, W. Hill. 2, H. Yardley. *hc*, J. Watts; W. Hill.
MAGPIES.—1 and 2, J. B. Bowden. *hc*, H. Yardley.
ANY VARIETY.—1, T. Rule. 2, H. Yardley.
JUDGES.—*Poultry and Pigeons*: Mr. T. J. Charlton, 23, Blenheim Road, Manningham, Bradford; Mr. S. Fielding, Trentham Park, Stoke-on-Trent.

BINGLEY POLY SHOW.

The seventh annual Show of the Airedale Agricultural Society took place on the 27th of August at Bingley. The following report on the Pigeons has reached us.

(From a Correspondent.)

PIGEONS.—Pouter cocks had four entries. A Blue was first; this bird also won the cup for the best bird in this and the three following classes. A White was second. In the hens Yellow and White were first and second. Of Carrier cocks there were four entries; both the winners were Blacks, and the judging of several previous shows was reversed, and in the opinion of all Mr. Allsop was right. In hens a good Dun and Black were the winners. Amoud Tumblers consisted of five pens, and four of them were birds such as are seldom met with at any show. In Tumblers, Any other variety, a grand Red Whole-feather was first, a Black Mottle second, and Red Agates were highly commended and commended. Barbs were a good class, Blacks were the winners. Foreign Owls were remarkably good; White was first, and Blue second. English Owls were a grand class of twenty-two pens; a good old-fashioned Silver was first, White second. A Silver, very highly commended, was the best-conditioned bird in the class, and with age will be difficult to beat. In Jacobins, Red or Yellow, a good Red hen was first, a Yellow cock second; and in Jacobins, Any other colour, a remarkably good White with perfect pearl eyes was first; this bird obtained the cup for the best bird in this, the preceding, and two following classes. A good Black was second. Of Fantails there were twenty-six pens of such birds as are seldom seen; twenty-four of them were Whites, one Black, and one Blue. The first-prize bird was the largest-tailed and best-carried bird seen for some time. The whole of this class was highly commended. Of Turbitts there were nineteen pens of all colours; Black was first, and Yellow second. In Dragoons, Blue or Silver, Blues were the winners of both prizes. Dragoons, Any other colour, had four entries, Yellow being first; this bird won the cup for the best bird in this, the preceding, and four following classes. A Red was second, Yellow being highly commended and commended. Of Short-faced Antwerps there were twenty-three entries; Red Chequers were the winners. Long-faced Antwerps had the same number of entries as the preceding class; Blue was first, a Dun second. In the class for Any other variety a Trumpeter was first, Blondinette second.

This was a good class. In the Selling class there were fourteen entries; Black Barbs first, Blue Owls second.

The arrangements were good, and the birds well fed and watered. The Show was held under a spacious marquee; and under the management of so good a Committee and enthusiastic and ardent a fancier as the Secretary, Mr. Thompson, all went smoothly and well. This was certainly the best Show of Pigeons we have seen in Yorkshire for some time. The entries reached 2½ pens, affording another proof, if any were wanted, that the single-bird plan is far the best.

GAME.—*Black or Brown Red*.—*Cocker*.—1, J. Forfane, Keighley. 2, W. Tiltson, Coates, Barnoldswick. 3, H. E. Martin, Southorpe, Fakenham. *Any other variety*.—*Cocker*.—1, C. T. Burton, Thurgold, Sheffield. 2, W. F. Entwisle, Westfield, Cleekeaton. 3, H. C. & W. J. Mason, Drighlington.
GAME.—*Black or Brown Red*.—*Pullet*.—1, H. Butler, Bradford. 2, W. Tiltson. 3, J. Mason, Worcester. *Any other variety*.—*Pullet*.—1, J. W. Thornton, Bradford. 2, M. Jowett, Bradford. 3, E. Ayskroyd.
SPANISH.—*Chickens*.—1, J. Leeming, Broughton. 2, J. J. Booth, Silsden. 3, J. Walker, Wolverhampton. *hc*, H. Wilkinson, Earby, Sipton.
DORKINGS.—*Chickens*.—1, T. Braden, Earby, Sipton. 2, T. Statter, Whitefield. 3, J. Robinson, Garstang.
BRAHMAS.—*Chickens*.—1, J. H. Pickles, Birkdale, Southport. 2, W. A. Taylor, Manchester. 3, P. S. Arkerhitt, Sutton Scarsdale.
COCHIN.—*Chickens*.—1 and 3, W. A. Taylor. 2, C. Sedgwick, Keighley.
HAMBURGHS.—*Any variety*.—*Cocker*.—1, H. Robinson, Baildon, Leeds. 2, J. Smith. 3, J. Robinson. *Pullet*.—1, C. Pamberton, Bingley. 2, E. Gill, Fearncliffe, Bingley. 3, J. Sni I.
HAMBURGHS.—*Golden-spangled*.—*Chickens*.—1, T. May, Wolverhampton. 2, J. Robinson. 3, J. Newton, Silsden, Leeds. *Silver spangled*.—1 and 3, J. Rollinson, Lindley. 2, J. Robinson.
HAMBURGHS.—*Golden pencilled*.—*Chickens*.—1 and 2, W. & E. Clayton, Morton Banks. 3, J. Preston, Alerton. *Silver-pencilled*.—1, J. Robinson. 2, H. Smith, Morton Banks. 3, J. Smith.
HAMBURGHS.—*Black*.—*Chickens*.—1, C. Sedgwick. 2, T. W. Holmes, Baildon. 3, J. Moore, Bingley.
GAME BANTAMS.—*Chickens*.—1 and 3, W. F. Entwisle. 2, G. Noble, Staincliffe, Dewsbury.
BANTAMS.—*Any other variety*.—*Chickens*.—1, W. A. Taylor. 2, R. H. Ashton, Mo tram. 3, J. Mitchell, Keighley.
ANY OTHER VARIETY.—*Chickens*.—1, J. Bowker, Keighley. 2, Rev. A. G. Brooke, Shirwardine. 3, C. Holdsworth.
ANY OTHER CLASS.—*Cock*.—1 and 2, J. I. Booth. 3, H. Andrews, Eccleshill. *Hens or Pullets*.—1, C. Carr, Wilsdon. 2 and 3, J. I. Booth.

PIGEONS.

POUTER.—*Cock*.—1, T. Rule, Gilesgate, Durham. 2, R. Fulton, London. *Hen*.—1 and 2, R. Fulton.
CARRIERS.—*Cock*.—1, R. Fulton. 2, H. Yardley, Birmingham. *Hen*.—1 and 2, R. Fulton.
TUMBLERS.—*Amoud*.—*Cup*. R. Fulton. 2, H. Adams, Beverley. *Any other variety*.—1, H. Adams. 2, R. Fulton.
BARB.—1, R. Fulton. 2, J. Lister, Keighley.
OWL.—*Foreign*.—1, H. Yardley. 2, R. Fulton. *English*.—1, Ward & Rhodes. 2, J. W. Edge, Erdington.
JACOBS.—*Red or Yellow*.—1, W. Croft, Killinghall, Ripley. 2, R. Fulton. *Any other colour*.—1, A. A. Vander Meersch. 2, R. Fulton.
FANTAIL.—1, O. E. Cresswell, Bagshot. 2, J. Walker, Newark.
TERBIT.—1, R. Fulton. 2, A. A. Vander Meersch.
DRAGOONS.—*Blue or Silver*.—1, W. Gamon, Chester. 2, Ward & Rhodes. *Any other colour*.—1, R. Fulton. 2, J. Watts.
ANTWERP.—*Short-faced*.—1, J. Lister, Keighley. 2, W. R. Wright, Birmingham. *Long-faced*.—1, R. Pritchard, Ludlow, Salop. 2, H. Jennings.
ANY OTHER VARIETY.—1, R. Fulton. 2, H. Yardley.
SELLING CLASS.—1, R. White. 2, J. Mitchell.

JUDGES.—*Poultry*: Mr. Richard Teebay, Fulwood, Preston. *Pigeons*: Mr. H. Allsop, Birmingham.

ALDBOROUGH AND BOROUGHBRIDGE POULTRY SHOW.

This was held on August 22nd. The following is the prize list:—

DORKINGS.—1, T. P. Carver, Langthorpe, Boroughbridge. 2, H. R. Farrer, Greenhammerton Hall. 3, H. S. Thompson, Kirby Hall. *Chickens*.—1, J. Newhall, Clifton, York. 2 and *hc*, T. P. Carver, Langthorpe, Boroughbridge. 3, H. J. Parish, Boroughbridge Hall.
SPANISH.—1, Palmer & Hawkins, Topcliffe. 2, H. R. Farrer. *Chickens*.—1, Pallister & Hawkins.
GAME.—1 and 2, J. Watson, Knaresborough. *Chickens*.—1, J. Robshaw, Whinley.
COCHIN-CHINA.—1, F. Horsman, Boroughbridge. 2, J. Sherwin, Ripon. *Chickens*.—1, Croft, Lendal, York. 2, F. Horsman.
BRAHMA POOTHA.—1, Mrs. G. Mangles, Givendale, Ripon. 2, H. S. Thompson. *Chickens*.—1, T. P. Carver. 2, Mrs. G. Mangles.
HAMBURGHS.—*Golden-spangled*.—1, E. Barnett, Thermanby. 2, T. Tweedy, Thirk. *Golden-pencilled*.—1, J. Sherwin. 2, J. Newhall. *Chickens*.—1, J. Watson. 2, P. Gill, Boroughbridge.
HAMBURGHS.—*Silver-spangled*.—1, A. Umpleby, Boroughbridge. 2, T. Tweedy. *Chickens*.—1, J. Walker, Ouseburn. *Silver-pencilled*.—*Chickens*.—1, J. Clayton, Thirk.
POLANDS.—1, C. Walker, Boroughbridge. 2, Mrs. Croft. *Chickens*.—1 and 2, C. Walker.
BANTAMS.—*Game*.—1, T. P. Carver. 2, H. S. Thompson. *hc*, J. Watson, jun. *Any other variety*.—1 and 2, T. P. Carver. *hc*, J. Sherwin. 3, J. Waddington, Gilsely.
FARMYARD CROSS.—1, W. Woodward, Munkip, Boroughbridge. 2, H. S. Thompson. *Chickens*.—1 and 2, T. P. Carver. *hc*, W. Woodward. 3, H. S. Thompson.
ANY OTHER VARIETY.—1, T. P. Carver. 2, J. Watson. *hc*, G. Rutherford, Thirk. 3, G. Slator, Ripon.
TURKEYS.—1, Mrs. Leck, Tholthorpe, York. 2, Mrs. G. Mangles. *Poultis*.—1, Mrs. G. Mangles. 2 and 3, W. Bekeridge. *hc*, Mrs. Kirk, Givendale, Ripon.
GEES.—1, Mrs. G. Mangles. 2, J. T. Renton, Ripon. *Goslings*.—1, Mrs. G. Mangles. 2, I. Moorey, Malwath, Ripon. *hc*, Mrs. Smith, Humbarton.
CHICKENS.—*Adelourey*.—1 and 3, T. P. Carver. *hc*, W. Woodward. 2, H. S. Thompson. *Ducklings*.—1 and 2, T. P. Carver. *houn*.—1, C. Graham, Aldborough. 2, G. Sadler, Boroughbridge. *Ducklings*.—1, G. Sadler. 2, Mrs. G. Mangles. *Any other variety*.—1, G. Sadler. 2, E. Thudry, Dalton, Thirk.
GUINEA FOWLS.—1, J. T. Renton. 2, Miss Kirk.
SELLING CLASS.—1 and 2, T. P. Carver. 3, H. R. Farrer.

PIGEONS.—*Pouters*.—1, G. Sadler. 2, F. Umpleby. *Carriers*.—1 and 2, G. Sadler. *Trumpeters*.—1, W. Kitchen, Fescovale. 2, C. Auton, Pettergate, York. *Jacobins*.—1, C. Auton. 2, G. Annald, Bishop Monkton. *Fantails*.—1, C. Auton. 2, W. Kitchen. *Tumblers*.—1 and 2, C. Auton. 3, W. Kitchen.

Darbs.—1, C. Anton. 2, J. Smith, Allhallowgate, Ripon. *Turbits*.—1 and 2, W. Kitchen. *Antwerp*.—1, T. Horsman, Ripon. 2, G. Sadler. *Owls*.—1, A. Umpleby. 2, G. Sadler. *Any other variety*.—1, W. Kitchen. 2, C. J. Garnett. *See also* C. Anton. *Selling Class*.—1, W. Scott, Boroughbridge. 2, A. Wells, Ripon. *See also* C. Anton.

FABRICS.—*Any Dress*.—1, A. Robson, Merton-on-Swale. 2, C. Anton. 3, J. A. Powell. *Do.*.—1, A. Robson. 2, C. Anton.

EXTRA STOCK.—1, W. Wilson, Boroughbridge (Guinea Pigs). Equal 1, J. N. Warnick, Langthorpe (Fantails).

JUDGE.—Mr. S. Burn, Whitby.

POLYGAMY IN PIGEONS.

PERMIT me to refer to the article under this title which appeared in "our Journal" of August 21st. The writer must excuse me if I am a little incredulous. I was once attending at a petty sessions, when some case or other came on, I forget what, but the question was asked (the people were quite in a humble rank), "My good man, are you married, now?" A little woman in a shawl immediately called out, "Yes, sir, he is, and here's the baby," at the same time holding up as high as she could an infant of a very few weeks old. The laugh can well be imagined, and the marriage was believed in. Now, to believe fully in this account of the polygamy of Pigeons I want to see the babies, not one, but four. The case given by "R. W." is so contrary to all my thirty-five years' experience as a Pigeon-fancier—indeed, I have never known or heard of anything of the kind. I do not for one moment impute the least atom of untruthfulness to "R. W.," but I think by reading his account some links in the chain of evidence are wanting. That Pigeons may change-over partners, this I believe. Was this case more than simply such an exchange?

"R. W." says, "I believe that the Blue cock regularly took his turn on each nest." Am I to understand that the "I believe" means "I surmise or think," or that it means "I know for certain?" Then how could one cock take his turn on each nest? for Pigeons, cock and hen, sit a regular time. Unless "R. W." not only believes but knows, I must doubt the statement. One cock was evidently the master cock and a great tyrant, as occasionally they are. I knew a cock Dragoon that was such a tyrant no one would keep him, and he was the source of a little income to the dealer who owned him, and sold him over and over again.

Next as to the hatching. One pair of eggs were broken, and though each contained a bird, the evidence as to variety is at an end. Those that were hatched I should like to have been seen when older, for three weeks is scarcely time to decide between such near colours as Black and Blue, for many Blues are very dark at first. Of the second hatching "R. W." states nothing as to colour, and the shifting to the care of nurses was unfortunate. Knowing how very easily mistakes are made with the best intentions, especially with respect to the habits, &c., of birds, I take the liberty to doubt at present that Pigeons are polygamous.

I will now briefly notice what I believe is not unusual, the strong preference which some cock Pigeons feel for one certain hen—I mean that one hen has many admirers. Mr. Darwin, I believe, thinks that the brilliant colours of the male birds are intended to attract the females; on the principle, I suppose, that young ladies at a garrison town are said to have frequent attacks of *scarlet fever*. Probably he is correct; fine feathers not only make fine birds but also attractive birds. In Pigeons, I think sometimes the male birds are attracted by any special beauty of a female. I had for some years an unusually pretty Buff Baldhead hen, always clean, always trim, and so pretty in colour and shape that strangers were wont to say, even though not Pigeon-fanciers, "What a very pretty bird that is!" Now this little hen was constantly being followed and cooed round by different cocks both mated and unmated; but to all her admirers she was wholly indifferent, and, like a good moral little lady, went calmly on with her duties as a wife and mother. I have had the case of a cock bird who was also pestered with an admirer of the opposite sex, and who beat her off for a time, and his lawful mate beat her too; but in the end, alas! he yielded, and left his partner to muse on the infidelity of husbands.

I think that when a Pigeon is attractive he or she is unusually good-looking. A regular old frump of a hen is not admired. The cocks who are tempted are lively, spirited, bright plumed birds, always cooing and showing themselves off to perfection—in fact, regular "gay birds." It is unfortunate for romance that the class of Dove known as the domestic Pigeon is neither gentle nor always constant, for they habitually fight, and fight pertinaciously, and they break pair occasionally; while one variety, the Pouter, will forget himself and his mate in a shameless manner with at least any unmated hen in the loft, but the Pouter is the most showy and cooing of all varieties, and hence very attractive.—WILTSHIRE RECTOR.

PROLIFIC TURKEY.—My Turkey hen has laid altogether eighty-seven eggs. She has often remained on the nest for twenty-four

hours at a time, but never properly settled to sit. She has discontinued laying for a few days, and then laid several eggs continuously again.—WALTER BISCOE.

PIGEONS AT HITCHIN AND EXETER SHOWS.

I REGRET I cannot agree with Mr. Fulton, that dealers are the great supporters of shows in the three kingdoms. Let the amateurs all retire, and what would be the use of dealing in birds? I for one, with many others, vote Messrs. Fulton, Yardley, &c., intense nuisances as exhibitors, and what we do is this—we find out if we can where they intend to exhibit, and then keep our birds at home, although not being prize-grabbers we cannot afford to help every committee to pay Mr. Fulton's prizes. If dealers would exhibit less we think it would be more to their advantage, and to the advantage of the birds also, which are now shown by dealers until they die, no use being made of them as stock during the breeding season.

As to the judgment at Exeter and Hitchin being reversed, it is quite possible that the condition of the birds was reversed, but as I was not at either show I cannot offer any remarks upon this; but one thing I do say, that if the judges are to be judged in the way they are at present, and with such intense animus that appears to prevail against at least some of them, I should think their services would be discontinued. As to expecting perfection in them, or anything else in this world, it is simply stuff. If you get them honest that must compensate for their deficiencies in awards, and as in these days the names are always published, if you do not like the judge, stay at home. Having acted more than once in the capacity, I know how pleasant it is to be surrounded by disappointed grumbling exhibitors, who in nine cases out of ten are wrong. The judges in England are pretty well known, so there need not be much difficulty about it. I have no personal feeling against either dealer mentioned; in fact, one I do not know. I believe Mr. Fulton to act as strictly and straightforwardly as a dealer can, but I still think that if dealers exhibited less, but less, they would find amateurs increase as well as their business. At present it stands thus, What is the use of showing? Mr. Fulton is sure to be there.—OBSERVER.

CLEANSING CAGE WATER-BOTTLES.

THERE are, doubtless, many of your readers lovers of pet birds, as I am, who have been puzzled, as I have been for years, to find the easiest and best method of cleaning the fountain bottles used in most bird cages. To begin, I ought to state that I take care of my birds myself, have been very successful in rearing Canaries, and have seldom lost a bird from disease of any kind. Some have flown away, poor, silly, little, short-sighted things; one or two have died of old age, gradually and painlessly; and a favourite hen once died while laying. Then, of course, there have been untoward accidents, such as the attacks of wicked malevolent cats, and twice a cage has fallen down. The first time my poor Dick's leg was broken, and though set with tender care he died. The second time a hen was jolted off her nest with her four young ones, which, as may be supposed, was not good for mother or chicks. Barring these accidents I have been a very successful owner of cage birds. But the fountain-bottles have been one of my life-long difficulties. Of course I like them to be clean and bright, but, in spite of all my pains, the green (some sort of algae) would accumulate on the insides of the bottles, and I found it a long and troublesome business to remove it. At the suggestion of various housemaids I tried eggshells, tea leaves, ashes, paper torn up in small pieces, &c., and at the suggestion of the housemaid's master several kinds of acids. All were effectual in time, but I have often spent an hour in cleaning one bottle. Now, my plan is so easy and so simple, I want to recommend it to all your bird-keeping readers. Put a little common garden soil, say two teaspoonfuls, into the bottle, washing it down with water. Half a dozen good shakes will make the bottle quite clean and bright, and remove all traces of green, and a rinse in clean water will make it fit for the prettiest little pet bird in the loveliest lady's drawing-room in England.—A LOVER OF ALL ANIMATED CREATURES.

SUBSTITUTING A LIGURIAN FOR A COMMON QUEEN.

I HAVE two stocks of bees in Woodbury hives, in one of which the bees had worked across the bars, so that I could not move them. Accordingly, about a fortnight since, I drove the bees into an empty hive, the bars of which were prepared as recommended in your "Bee-keeping for the Many," and I am glad to find they are working their combs straight. I intend to feed them well.

I am desirous of knowing if I could obtain and join to this stock a Ligurian queen, and if this would be a good time for so

doing. Will you also kindly inform me where I can procure a pure fertilised queen, and the proper course to be followed to ensure a successful union?—G. M. F.

[As you do not appear to have utilised the combs already constructed in the first hive, we fear that you will have but a very small amount in the new box at the present time. An enormous quantity of artificial food would be necessary to enable the bees to supply the deficiency in combs, and to lay in sufficient store for the winter. Under these circumstances we should not advise your incurring the expense of a Ligurian queen with the risk of losing the stock during the winter. You could, however, try the experiment with your other live now, or wait until next spring to see if the transferred colony would then be in a sufficiently prosperous condition. There is no objection to the present time, other matters being suitable, for exchanging Ligurian for common queens. If you determine on making the attempt, write either to Messrs. Neighbour, Regent Street, London, or to Mr. W. J. Pettitt, Dover, either of whom will supply you with a reliable queen, and with instructions as to the best mode of proceeding to ensure a favourable result.—Evs.]

HONEY SEASON IN GLOUCESTERSHIRE.

I HAVE received a letter from a bee-keeper in Gloucester giving a very poor report of the season in his vicinity. He states that "Everybody who keeps bees about here is sadly complaining of want of luck this year. I went out yesterday two miles in the country to see a person who had taken two hives, an old stock and a swarm of this summer, and only obtained 12 lbs. of honey from the two. At another place, where there were eight hives, the owner destroyed four, and took but 12 lbs. from the whole. I have taken one super with 17 lbs. and another small cap with 5 lbs. There was a good deal of dark comb and some brood in one of the supers."

This general deficiency of honey, and the prevalence of breeding in supers, continue to be the complaint from all parts of the country. I should be glad to hear at the proper time what bees may have done at the heather this autumn.—S. BEVAN FOX, Exeter.

RAPID PICKLING OF MEAT.—Roll the meat in a mixture of 16oz. salt, 1 oz. saltpetre, and 1 oz. sugar, so that all parts may be completely salted; then wrap closely in a piece of cotton cloth previously well scalded and dried, and place in a porcelain or other vessel. The cloth is essential with small pieces, to contain the brine formed in contact with the meat. After about sixteen hours, however, some brine will drain off into the bottom of the vessel, and it will be necessary then to turn the meat, still wrapped up, daily. A piece of 6lbs., treated in this way for six days, then unwrapped and boiled, will be found quite palatable and sufficiently pickled. For larger quantities the cloth may be dispensed with, since the brine formed will be sufficient to cover the mass, provided the pieces are closely packed, and any unavoidable cavities filled with stones.—(English Mechanic.)

OUR LETTER BOX.

DONKEY AND MEIGLE, POULTRY SHOWS.—These were local shows, not advertised.

BUCKWHEAT FOR FOWLS.—"I read in your number for August 14th, in answer to 'COLNE,' "Buckwheat is not good for fowls." How am I to reconcile this with Wright and other authorities?—ELICEE."

[The authority we consult on subjects connected with poultry-keeping condemns buckwheat as a poultry food; but we know it is used as a pleasant food by gamekeepers, and good authorities speak in its favour for poultry; so, as you have purchased some, you will do wisely to try it and thus test its merits. We do not know where you live, but if near Suffolk or Essex you might readily obtain it if you call it "brank."] "

GAME FOWLS' PLUMAGE (J. Fovial).—We have submitted your letter to Mr. Wright, and his reply is, "I will communicate with him direct if he wishes." Mr. Wright's direction is, "at Messrs. Cassell & Co.'s, Editorial Department, La Belle Sauvage Yard, Ludgate Hill, London, E.C."

NORTHERN COUNTIES COLUMBARIAN SOCIETY.—The gentleman who won the first prizes in the classes for Pouters, Tumblers, and Foreign Owls was Mr. Townson, of Bowdon, not Messrs. Townson, of Ezzemont, who did not exhibit.

KEEPING WOOD PIGEONS IN CONFINEMENT (E. A.).—A single, even a very large one, would be a small place for Wood Pigeons; a room, or shut-in loft, would be better. We say shut-in, as when adult they would be certain to fly away and not return, all attempts to domesticate them and cure their roving propensities having failed. Brought up from the nest and confined to a room they will be fairly tame, and possibly may breed. Give them for food peas, barley, or wheat. If healthy and kept well fed and clean, they will live four years. Mind not give water for drinking and bathing.

UNITING SWARMS (Ignorant).—We think your surmise is correct. The swarm of August 14th doubtless came out of your second hive in the glass case; but as this cannot be moved about without danger of falling to pieces, we should not meddle with it. Why not break it up if it has few bees and no honey? You might smoke the bees out of it, and save all but the drones; but if these are not yet got rid of, and the bees are few in number, we should be inclined to destroy them, as of no probable value. As to the swarm, we should feed it up at whatever cost, seeing that your stock of bees is so

limited. It would pay well another year with a fair honey harvest. (Bee).—You can most easily unite any number of stocks by simply driving the bees of each hive, one after the other, into a common empty hive, and then dashing them all out in a heap in front of the stock you wish to keep. It is not too late to drive bees. If you put this on the ground in an open space, just tilting up one side of it on a bit of wood or a stone, all the bees will march up into it without any fighting whatever. Of course they will settle between themselves who is to be the reigning mother. Blow a little smoke in at the entrance of each hive before you begin to operate.

HONEY DEFICIENT—UNITING SWARMS (An Old Subscriber).—We sympathise with your disappointment, having no honey harvest whatever ourselves this year, but we do not despair. We shall feed largely, and advise you to do the same, beginning towards the middle of September, and feeding mostly by night. It will be good policy also to unite all weak hives to their stronger neighbours. No method of uniting stocks can be simpler or more effective than that recommended in this day's Journal to another inquirer. Drive two or more stocks of neighbouring bees into some common hive or box, and dash them out on the ground in front of the hive you desire to strengthen; but we would drive out the population of this hive as well, and then return the whole united bees to it in the way prescribed. Write again if you want further information. Driven or united bees need not be far removed from each other.

TRANSPORTING HIVES (An Old Subscriber).—You will find your queries fully answered next week. Let us know how you succeed.

REMARKS.

27th.—A fine day, though there was a little rain once or twice.
28th.—Very dark at 7.30 A.M., but fine soon after; heavy rain soon after noon; thunder at 3.25 P.M., with two or three heavy showers, and much strong wind during the day.
29th.—Bright, though raining at 8.30 A.M.; fine at noon and till 6 P.M., from that time showery.
30th.—Fine pleasant day.
31st.—Rain early, but fair by 9 A.M.; cloudy before noon and till 6 P.M., when it rained heavily; wet evening.
Sept. 1st.—Rather dull, but not raining in the middle of the day, but several showers in the evening; fine night.
2nd.—A very showery day, with bright gleams of sunshine between the showers.
Showery week and much lower temperature, in fact (except the minima) lower than for many weeks past.—G. J. SYMONS.

COVENT GARDEN MARKET.—SEPTEMBER 3.

A LARGE supply of fruit comes into the market; a difficulty in clearing it.

From observations taken near London during forty-three years, the average day temperature of the week is 68.3; and its night temperature 45.9. The greatest heat was 88°, on the 13th, 1865; and the lowest cold 25°, on the 12th, 1869. The greatest fall of rain was 0.99 inch.

ORNAMENTAL PLANTING.—No. 8.
AVENUES.

AVENUES for carriage-drives may be classed as of two distinct kinds: in one the trees are sufficiently near for the branches to meet across the drive and form a living arch high overhead; in the other they are kept so far apart and so far from the sides of the road, that each tree has ample space to become a fine specimen by the development of the full proportions and peculiar features of its species. The aspect of an arched avenue is peculiar and striking, and its formal and stately appearance is not displeasing when the situation is well chosen. Due attention is not always given to this important point, for I have seen drives from which fine views have been shut out by the compact but misplaced and unmeaning margin of trees. Instances there are, too, of belts of lofty trees intervening between a lawn and beautiful park scenery; and although the shelter of the trees might be necessary, it could have been obtained almost equally well by a series of groups so arranged as to afford pleasing views of the scenery beyond.

Like every other feature of ornamental planting, an avenue must have expression, or, in other words, there must be an apparent reason for its presence, otherwise it will fail to please, however fine it may appear. The most suitable position, then, for the formation of an avenue, which in time may become a living arcade, is along a drive leading in a straight line from an entrance lodge to the residence, to some important place or object, or, when the drive passes through plantations of under wood. In the first instance a glimpse of the mansion at the further extremity of such a noble gallery seems to welcome the visitor, and imparts a pleasing unity and expression to it: in the second, the sides of the avenue, without altogether concealing the green woods behind them, serve to break the monotony, and impart an importance and interest to a part of the drive that would otherwise appear very tame.

The length of straight avenues should be limited to a furlong, or at most two. A straight line that stretches away till it is lost in the distance is fatiguing to the eye, and is almost devoid of any feature that is graceful or interesting: to my mind it is a symbol of power or force and nothing else; and when a drive is very long a few curves may be introduced, without materially adding to its length, while the ever-valued charm of variety is gained. An avenue for such a drive should be of a wide and open character, with the trees of kinds that are remarkable for size and symmetry. There are few trees equal to the Chestnut for such a purpose, but it, like the Oak or Elm, attains so slowly to the huge proportions which we admire so much, that the planter knows full well that a generation or two of frail humanity must pass away before his work will obtain its full need of admiration, and therefore that he is planting for posterity.

Avenues of such noble old trees are exceedingly rare,
No. 65.—Vol. XXV., NEW SERIES.

yet the sight of one is enough to excite in anyone for whom such things have an interest, a strong wish to be the founder of a scene of such magnificence. In Maresfield Park, nearly opposite the entrance to the by-road leading to Messrs. Wood's nursery, there are three very fine old Chestnuts which are perfect models of what trees for an open avenue should be; the immense boles are crowned with numerous huge spreading branches, which from the freedom of their wide-spread growth clearly show that no other trees have ever grown very near them. Like the Oak, the Chestnut does not form a lofty stem when its branches are exposed to the full play of air and light, but it bestows its full vigour upon the leading branches which spring outwards and upwards from the stem at a few yards from the ground. In striking contrast to the spreading habit which is induced by such an ample breathing space, I may instance the fine Chestnut knoll in Godington Park, near Ashford, in Kent, where the crowded trees are more than twice as high in stem and branch as those at Maresfield, and although so lofty as to be remarkable, they are not individually very picturesque. The longevity of the Chestnut is another important merit: the great age to which it is known to live being very far in excess even of that of the Oak. In an orchard at Norton Court, near Faversham, there is a Chestnut of very similar appearance to the Tortworth Chestnut, and which is said to be several hundred years old.

Next to the Chestnut I would place the Beech, which, from its stately air and the graceful sweep of its branches, has been most aptly termed the "Lordly Beech." Then come the Oak, Elm, Lime, and Horse Chestnut among deciduous trees; and among Conifers the Wellingtonia, Cedrus Libani, C. Deodara, and Araucaria imbricata. Individual taste will doubtless suggest others, but I have intentionally restricted my list to a few very choice kinds that are certain to make a fine appearance wherever they are found to flourish.

For a close-arched avenue the whole of the deciduous trees already named answer admirably, and of Conifers we may take the Scotch Fir; Pinus Cembra, which has such strikingly beautiful bark when it is old; Norway Spruce, with its dense growth and very ornamental pendant branches that droop abruptly downwards from the stem, and yet curve upwards and outwards far from it, with the lateral growth or branchlets suspended from beneath like clusters of long green tassels; and to these may be added Pinus austriaca and P. macrocarpa.

The arrangement of the distance apart of the trees for either kind of avenue is an important but not a difficult matter if the planter remembers that for a tree to grow to a large size its branches must be tolerably exposed to the healthy influence of air and light. For narrow avenues, 30 to 50 feet apart, according to the kind of tree used, would be ample; while for an open avenue, or, to use a more expressive term, an avenue of noble specimens, double that distance, or even more, would be requisite; for in order that a fine tree may display its full beauty it should not stand very close to another, but should have a considerable sweep of turf beyond the

expanse of its branches, so that while the avenue is unbroken, yet each tree may be regarded with pleasure for its own intrinsic merit.—EDWARD LUCKHURST.

THE HORTICULTURAL EXHIBITION AT MANCHESTER.

SEPTEMBER 3RD, 4TH, 5TH, AND 6TH.

ONE of those great efforts at horticultural exhibitions which are made periodically was held last week at Manchester under the title of "The Grand International Horticultural Exhibition of Fruits, Vegetables, Autumnal Flowers, &c." The Show was held in the Botanical Gardens, and though inaugurated and conducted throughout by an independent body, it was under the auspices of the Botanical and Horticultural Society of Manchester. The conception and execution of this was a bold venture, involving, as it did, a prize list of £1100. But if such a venture is to be made at all, Manchester is the place wherein to make it, and where there are so many people, as Lord Derby said, "to whom the parting with £100 note could be an operation so familiar and so customary, that they would hardly know they had done it." Yet these Manchester men are business men, and liberal as they are, they do not give their money without a shrewd idea that it will be spent to some purpose; and the result of the effort that has been made we have no doubt has proved satisfactory to them in the production of an autumnal show, the like of which has never yet been seen in the provinces.

The Show was formally opened by Lord Derby on the 3rd inst., and its leading feature was Grapes and a fine display of vegetables. As concerned fruit generally, it may be said to have been meagre. It was yet too early for our hardy fruits, and if the Show had been postponed to embrace them it would, probably, have been too late for the Grapes. It is evident, therefore, that these were to be the great attractions of the Show, and so they were. In our report, which follows, full particulars will be given of them. Of autumn flowers there was also a good exhibition, especially of Gladiolus, Dahlias, and cut flowers. But in no respect was the Show international, except as between "John Bull, Sandy MacDonald, and Pat Murphy," as old Donald Beaton used to say. Our continental neighbours were conspicuous by their absence, and so the British gardeners had all the competition to themselves.

The arrangements were very good, and admirably carried out; and whatever merit there is in this respect is due to Mr. Bruce Findlay, Curator of the Botanical Gardens, to whom the direction of the whole was entrusted, and with whom and Mr. John Shaw, we are informed, the conception mainly originated. The fruit was shown in the conservatory, a handsome spacious glass structure, 150 feet long by 60 wide, on six tables running longitudinally the whole length of the building, and the flat effect which always attends a fruit show without some accessories was entirely relieved by the permanent climbers that clothed the pillars and rambled in free luxuriance overhead, while the available area of the house was furnished with exhibitions contributed by Mr. B. S. Williams and Mr. William Bull, of London; Messrs. Cole, of Withington; and Messrs. Dixon, of Beverley. These consisted chiefly of fine-foliaged and new and rare plants, and were highly meritorious; the names of the exhibitors being a guarantee for the quality of the plants. The fine fruit was, therefore, well set off, and the eye was not wearied with monotony.

Running at right angles to the western end of the conservatory was a large canvas tent, probably 100 yards long and 20 wide. This was skilfully laid-out in the gardenesque style with centre beds, and raised winding terraces at the sides. To these were devoted the exhibition of plants and autumnal flowers, with groups and settings of fine-foliaged plants interspersed. This great tent was supported by a frame of woodwork, the pillars of which were covered with Ivy, thereby taking off the naked look which they would otherwise have had, and which is so objectionable in all such structures when they are unprotected. One of the best coverings we have ever seen of this sort is of sprays of Scotch Fir and Spruce nailed to the pillars. At one end of this tent there was a bank of Gladiolus exhibited by Messrs. Kelway, of Langport, which could not but rivet the attention of all lovers of this splendid autumn flower. A little lower down was a trophy of vegetables exhibited by Messrs. Dickson, Brown, & Tait, of Manchester, arranged with much skill and taste, and forming a prominent object in this part of the Exhibition. In the furnishing of this portion for effect the

merit is due chiefly to Mr. John Shaw, of Bowden; Messrs. Barron & Son, of Borrowash; and Mr. R. S. Yates, of Sale. Messrs. Jackman & Son, of Woking, had a splendid group of their new popular Clematises, which attracted much attention; while Mr. J. T. Peacock contributed a fine collection of succulents from his fine collection at Hammersmith. Messrs. Lane and Son, of Berkhamstead, had a fine exhibition of Ivies; and Mr. Richard Smith, of Worcester, one of evergreens.

Besides these two departments there were others more detached, one a great tent containing the vegetables, and the other the Potatoes. On the terraces surrounding the conservatory were fine specimens of Conifers in tubs, shown by Messrs. Barron & Son, of Borrowash, and Mr. Maurice Young, of Godalming. Numerous implements and garden structures, boilers, and heating apparatus were also exhibited, which will be alluded to anon.

Such an occasion would not have been complete without a dinner, and this was seized by the President and Council of the Manchester Botanical and Horticultural Society to issue invitations to the leading horticulturists present at the Show. About 150 accepted the invitation, and sat down to a splendid banquet presided over by Lord Derby, in the Hulme Town Hall. It is not usual publicly to criticise the hospitality of one's host, but on such an occasion it is admissible, and especially so when the preparations and arrangements are such as to serve as a pattern to those who are fond of getting-up public dinners and testimonial entertainments. Some of our metropolitan caterers may profitably take counsel with Mr. Bruce Findlay, to put them in the way of knowing how to dine a large assembly, not only sumptuously but in comfort. In concluding these preliminary remarks we have only to add that the whole arrangements were perfect, and we neither saw nor heard of anything occurring to ruffle the susceptibilities of the most sensitive, or to cause pain or disappointment to anyone.

FRUIT.

THE great strength of the fruit display lay in the collections, which were truly grand, and for which valuable prize were offered. Of Grapes, the show was very large, but that of Apples and Pears very weak. The period of the season was, of course, somewhat early for these fruits, and in October a better show of them would, no doubt, have been secured. It seems a pity that the promoters, having had the opportunity of making a grand exhibition of the fruits of this and other countries, did not fix the date later, so that not only Grapes, but what are after all the great standard fruits of the country, Apples and Pears, would have been well represented. The Exhibition would then have been, what it was not in any sense of the word, international.

COLLECTIONS.—For a collection of twenty kinds of fruits, comprising not more than six kinds of Grapes, two kinds of Pine Apples, and two kinds of Melons, prizes of £30, £20, and £12 were offered. Here Mr. G. Johnston, gardener to the Earl of Strathmore, Glamis Castle, Forfar, made a most magnificent display, being a long way ahead of his competitors, and so he was the winner of the premier prize of the Exhibition. His Grapes—Black Hamburgh, Muscat of Alexandria, Buckland Sweetwater, and Black Alicante—were very fine; likewise the Nectarines—Pitnastown Orange, Elruge, &c. Peaches were represented by Sulhamstead (a variety of the Noblesse), Grosse Mignonne, and Red Magdalen; Pines by the Smooth Cayenne and Ripley Queen; with these were Brown Turkey Figs, Melons, &c. In every respect this was a most meritorious display. Mr. Jones, Royal Gardens, Frogmore, and Mr. Grant, gardener to J. B. Glegg, Esq., Chelford, were second and third respectively. In collections of fifteen kinds of fruits three very good lots were staged. The first prize of £20 was awarded to Mr. Simpson, gardener to Lord Wharfedale, Wortley Hall, who had good Grapes—Black Hamburgh, Muscat of Alexandria, &c., and Enville and Smooth Cayenne Pine Apples, Melons, Peaches, Nectarines, Jargonelle Pears. Mr. Upjohn, gardener to the Earl of Ellesmere, Worsley, was awarded the second prize for a lot nearly equally fine. The Grapes were very good, some examples of Gros Colmar especially so, and a dish of Violette Blative Nectarines in this collection were peculiarly pretty. For the collection of ten kinds of fruits, exclusive of Pines, there was also a good competition. Mr. Miles, gardener to Lord Carlington, Wychcombe Abbey, Bucks, was awarded the first prize for very excellent Grapes, Peaches, Nectarines, Figs, Pears, &c. Mr. Bain, gardener to Sir C. R. Broughton, Bart., Ludlow, obtained the second prize for some very large, but rather coarse, examples of Grapes, both black and white; good Peaches, Nectarines, &c. The third prize fell to Mr. T. Bannerman, gardener to Lord Bagot, for a very excellent lot. For the collection of twelve kinds of hardy fruits on a basket or tray, the first prize

was awarded to Mr. Cox, gardener, Madresfield Court. The fruit was all good, but having to be exhibited in a cramped space—in this instance on an old tea-tray—it had a poor appearance.

GRAPES.—So plentifully were these exhibited, and in many cases so extremely fine, that they formed the greatest attraction of the whole Show. The prizes offered for Grapes were large, and they were divided into numerous classes to suit exhibitors of all grades. The general character of the display was good, the most striking feature being, however, perhaps the great size of the bunches rather than the fineness of the quality. We do not know that we have ever seen such large bunches so well finished of many of the varieties, but we have certainly seen an infinitely superior show of Black Hamburgs years ago, and we almost venture to say Muscats. The display at Manchester this year was superior as regards quality, taking it *en masse*, to that at Glasgow last year; many very poor exhibits, however, were staged, and by some of our reputed Grape-growers too, which it would have been well for them to have left at home.

The finest and best dish of Grapes in the Exhibition was the Madresfield Court, exhibited by Mr. Meredith, of Garston, which won for him the first prize for two bunches of Grapes in commerce three years prior to the Exhibition. The second prize was awarded to Mr. Cox, the raiser, for the same variety, and the third prize also was given for Madresfield Court. It is satisfactory to find that this new Grape is proving itself so well. For the best seedling Grape not in commerce, the first prize was nobly won by Mr. Thomson, of the Tweedside Vineyard, Galashiels, with the Duke of Buccleuch, a truly grand Grape in every way. Mr. Hunter, gardener to the Earl of Durham, staged a white variety, named Lambton Castle Seedling, which was simply the White Tokay. For the heaviest bunch of black Grapes, a noble specimen of Black Hamburg, 13 lbs. 2 ozs., the heaviest of this variety on record, we believe, was shown by Mr. Hunter, of Lambton Castle. It was well coloured for its size, but, as usually is the case with large bunches, it is more of a cluster than a bunch. The next heaviest was a Barbarossa, weighing 5 lbs. 14 ozs., from Mr. Dickson, gardener to J. Jardine, Esq., Langholm, which, although not very well coloured, was clearly entitled to the second prize; it was, however, passed over for a better coloured example of Black Hamburg 1 lb. less in weight, from Mr. Coleman; and a still smaller bunch from Mr. Bruce, gardener to James Fildes, Esq., received the third prize. The heaviest bunch of white Grapes was sent by Mr. Dickson, gardener to J. Jardine, Esq., Langholm, N.B., the same exhibitor who at Glasgow last year staged the largest bunch on record of the White Syrian, weighing over 21 lbs.; the example this year was a trifle over 16 lbs.

Coming now to the *pièce de résistance* among the Grape classes. For ten varieties, one bunch of each, there was a grand contest, the examples from Mr. Hunter and from Mr. Johnston being very fine. Mr. Hunter staged 1, Muscat of Alexandria; 2, Mrs. Pince; 3, Raisin de Calabre; 4, Black Hamburg; 5, Golden Champion, 5 lbs. 3 ozs.; 6, Gros Guillaume, 9 lbs. 4 ozs.; 7, Black Alicante; 8, Lambton Castle Seedling (White Tokay); 9, Bowood Muscat (Muscat of Alexandria); 10, Pennington Hall Hamburg (Gros Guillaume), thus making in all only eight distinct varieties. Now, according to strict justice this collection ought to have been disqualified. The Judges, however, may have felt, as we felt, that it would have amounted almost to a cruelty to have done so; the exhibitor, no doubt, having shown them as, and believing them to be, distinct. The first prize of £15 was, therefore awarded to Mr. Hunter, who may be dubbed at present as the champion Grape-grower. The champion, Mr. Johnston, Glamis, made a good second. His examples of Raisin de Calabre, Buckland Sweetwater, Lady Downe's, Mill Hill Hamburg, Black Alicante, White Nice, Bowood Muscat, Aramon, &c. were very fine, the bunches averaging between 5 and 6 lbs. and being well finished. Mr. Hill, Keele Hall, came in third with much smaller but nice examples.

For five varieties of Grapes, one bunch of each, there was a strong competition—over twenty entries. Mr. Hunter was again placed first with very large and truly fine examples of Black Hamburg, 9½ lbs., a fine bunch; Black Alicante, Raisin de Calabre, Gros Guillaume, and Muscat of Alexandria. Mr. Bruce, gardener to J. Fildes, Esq., was placed second with very excellent examples also, but much smaller than Mr. Hunter's. For three bunches of Black Hamburg Grapes there were twenty-eight competitors, many of the bunches being of but ordinary quality. The first prize was most worthily awarded to Mr. Coleman, Ledbury, for three perfect examples, cut from a Vine sixty years old. The next lot in point of merit came from Mr. Hunter; the bunches were large, moderately well coloured, and with fine berries. These were, however, passed over for much smaller examples, a little better finished, from Mr. Temple, gardener to the Duke of Marlborough, Blenheim, and some similar from Mr. Bruce were third.

Colour seemed to be the test with the black Grape; but to be consistent the same rule should have been applied to the

white ones. In the very next class—three bunches of Muscat of Alexandria, the best ripened and the finest coloured lot came from Mr. J. Wakefield, gardener to R. F. Gretton, Esq., Burton-on-Trent, and these received no prize at all. The first prize was awarded to fine examples, large both in bunch and berry, but a little green, from Mr. Hunter. The second prize was awarded to Mr. Roberts, gardener to the Earl of Charleville, Charleville Forest, Ireland, for noble examples very large in berry, and of a peculiar delicate colour, but a little over-thinned. Mr. Meads, gardener to Raikes Currie, Esq., Farborough, was placed third with very pretty examples, having a most lovely tint. Many other excellent exhibits were made in the class.

For three bunches of any black Grape (not Black Hamburg), Mr. Coleman carried off the first prize with fine examples of Lady Downe's, very large in berry. Mr. Bruce was placed second with excellent Gros Guillaume, named Pennington Hall Hamburg. Mr. Meredith was third with Madresfield Court. Some fine examples were also shown of Muscat Hamburg and Alicante. In the corresponding class for white Grapes Mr. Hunter was again first with large and very fine examples of Golden Champion, Mr. Hill being second with Foster's White Seedling, and Mr. Goodacre, gardener, Elvaston, third, with Canon Hall Muscat. For the best collection of such kinds of Grapes as are not included in the other prizes offered, Mr. Hunter was again first with fourteen varieties of very good quality. Messrs. Lane and Son, Berkhamstead, exhibited twenty-one varieties, not so good, however, as in Mr. Hunter's, and received the second prize. For ornamental baskets of Grapes, not less than eight varieties, single baskets were staged, containing a bunch of each. The Grapes were good, but neither the baskets nor the manner of exhibiting was ornamental. Mr. Roberts, Charleville, obtained the first prize, Mr. FAnson second, and Mr. Upjohn third. Messrs. Lane & Son had an extra prize for a large very elaborate stand of eight baskets of distinct varieties, but which was anything but ornamental.

PINES.—Of these the exhibition in point of numbers was meagre, the encouragement given by the small prizes offered being small in comparison with the almost lavish expenditure for Grapes. If poor in number, however, in quality the Pines were extremely good. Mr. C. Sandford, gardener to the Earl of Bective, Kirkby Lonsdale, had the honour of producing the largest Queen Pine in England or anywhere else, so far as we know. We were curious to ascertain carefully the weight of this noble fruit, and found it was just 8 lbs. 4 ozs. It was, of course, awarded the first prize in the class for one Queen Pine Apple. The next surprise here was in the class for two Pine Apples, any other kind. In this Mr. Miles, gardener to Lord Carington, carried off the first prize with truly magnificent fruits of the Enville Queen, weighing respectively 9 lbs. 14 ozs. and 9 lbs. 9 ozs. These were certainly two of the finest fruits of that variety we have seen. Mr. Miller, Workop Manor, was first for the two Queen Pines; Mr. Jones, Frogmore, was first for the Smooth Cayenne; and for any other kind Mr. Miles was first with a fair fruit of Providence.

PEACHES, NECTARINES, AND APRICOTS.—Here Mr. Johnston, of Glamis, came well to the front. In the class for four dishes of Peaches, six in a dish, Mr. Johnston was first with very fine fruits of Noblesse, Grosse Mignonne, Sulhamstead, and Red Magdalen. Mr. J. Louden, gardener to T. Barnes, Esq., was second with two dishes of Noblesse and two of Royal George. In the class for twelve Peaches, three kinds, Mr. Malcolm, gardener to Lord Cholmondeley, Nantwich, was first with good examples of Royal George, Belle Beaunce, and Noblesse. Mrs. W. G. Siddall, Cheltenham, was second with Barrington, Grosse Mignonne, and Noblesse; and Mr. J. Barnes, Gloucester, third. For six Peaches, any kind, the competition was very strong. Mr. J. Park, Railway Cottage, was first with very fine Noblesse. Mr. Hind, gardener to Sir S. E. Moss, Bart., Roly, was second with Grosse Mignonne; and Mr. Beesley, gardener to R. Aders, Esq., Whalley Range, third with Grosse Mignonne.

In Nectarines, three kinds in fours, Mr. Grant, gardener to J. B. Glegg, Esq., was placed first with fine Elruge, Pitmaston Orange, and Balgowan; Mr. Cox second. For twelve Nectarines, three kinds in fours, Mr. Johnston staged some very fine examples, and obtained the first prize; the varieties were Duc du Telliers, Murrey, and Pitmaston Orange, all very fine. It is not a little remarkable that the best Peaches and Nectarines should come from so far north. For the best six Nectarines of any kind, Mr. Hind was first with very fine examples of Violette Hative; Mr. Malcolm second with Fine Apple; and Mr. J. Taylor, Huyton, third with Pitmaston Orange.

Apricots were poorly represented, the Moorpark being the only variety exhibited. Mr. Hill was first, Mr. E. Rooker second, and Mr. J. Larking third. For the best six fruits Mr. Malcolm was first, Mr. Jennings second, and Mr. Larking, Chipping Norton, third.

MELONS.—Of these a goodly number was staged as usual, but judging by appearances, the greater portion were very inferior. In the green-fleshed class Mr. D. T. Fish was the winner with a fruit named Queen Emma, but which was very distinct from

that variety. It was stated to be of very excellent quality, but its appearance was not at all prepossessing. Mr. Miller, Work-sop, was second with a variety named Lord Napier. Mr. Temple, Bienenheim, was first in the scarlet-fleshed class.

PLUMS.—Of these there was a fair supply, but they were not well displayed. In the class for twenty Plums, five kinds, Mr. Jones, Frogmore, was first with Magnum Bonum, Green Gage, Washington, Goliath, and Victoria, all very excellent examples. In the class for twelve Plums, Rivers's Early Favourite from Mr. J. Morris, Braintree, was placed first, Victoria (Denyer's) being second.

PEARS AND APPLES.—Pears, if we except the Jargonelle, were not well exhibited. Mr. C. Rylance, Ormskirk, was placed first with these for very good examples. In the collection of Pears, twelve kinds, two of each, the best lot came from Mr. Jones, Frogmore; they were, however, passed over. Mr. G. Miles obtained the first prize with Beurré Diel, Louise Bonne of Jersey, Gansel's Bergamot, Duchesse d'Angoulême, Pitmaston Duchess, Glou Morceau, Catillac, Brown Beurré, Knight's Monarch, and Williams's Bon Chrétien. This, as well as all the other collections, was placed on a small dish and huddled-up, having a very hilly appearance. The tickets, in many collections, were badly placed, and in some horrible mis-spelling occurred. The same remark applies to the Apples, the exhibition of which was very poor. Creditable examples stood forth here and there, but the great mass was miserable for an important show like this. Mr. Webb, of Calcut, was placed first for baking Apples, and Mr. Jones Frogmore, first for dessert in the collection classes. For the single dish of dessert Apples Mr. Webb was first with very fine examples of Red Astrachan.

Figs were not largely shown, the principal variety being Brown Turkey.

GOOSEBERRIES, considering the lateness of the season, were well shown, the chief variety being Red Warrington; the best coming from Mr. J. Hodder, Prestbury, Cheltenham.

CURRENTS, RED AND WHITE, made also a good display, the examples being very large and fine.

TOMATOES were here included amongst the fruit classes; whether intended for dessert or kitchen we were not informed. For four distinct kinds, three of each, the first prize was awarded to Mr. Hunter for four dishes which were decidedly all the same kind; at all events it was impossible for the Judges to observe any distinction.

FRUIT TREES IN POTS.—For two Vines in pots Messrs. Lane and Son had very large plants in large pots bearing an abundant crop of fair fruit. Peaches in pots were very poor, and the same remark applies to Figs. For two Pine Apples in pots in fruit Mr. Hunter, Lambton Castle, staged some good examples of a seedling variety which promises well. They were, however, quite green and unripe.

FRUITERS' COLLECTIONS.—Among the collections of fruit open to fruiters only some good exhibitions were made, the fruit in many instances being very fine and in great quantity. For the largest collection the first prize of £20 was awarded to Mr. Mason, Dolton. Mr. W. Copeland, Manchester, who was second, had a collection nearly equally good. In his stand we observed two large and fine baskets of Duke of Buccleuch Grape. In the class for collections of fifteen kinds of fruits the first prize was awarded to Mr. Robert Jennings, Manchester; in his exhibition, however, there were only fourteen kinds, so that he ought clearly to have been disqualified. Mr. F. Stevenson, Altrincham, was placed second. It is greatly to be regretted that the collections of fruit which were entered for competition in these classes by Mr. Thomas, Jersey, did not arrive in time. We believe they were detained on the railway and only reached the show-ground late on the morning of the opening day, and were refused admittance without the knowledge of the Curator. Instead of being exhibited, therefore, they were sold in Manchester market.

VEGETABLES.

Not the least interesting, though perhaps not the most attractive, part of this great Show at Manchester, was the collections of vegetables sent from nearly all parts of England. These vegetables were exhibited in a large tent on the north side of the conservatory, extending nearly its whole length. There was also a supplementary tent in another part of the grounds adjoining the promenade or open space in front of the range of booths, which was set apart for the exhibition of Potatoes, of which there was a large and most interesting collection, and to which we shall refer again.

In the large tent adjoining the conservatory, the first thing that struck us on entering was a remarkably fine collection of vegetables shown by Mr. John Holder, of Cheltenham, to which the first prize was awarded. The wording of the schedule, "For the largest and most meritorious miscellaneous collection of vegetables, including all kinds" (open), left much to the individual judgment of the exhibitors, and we are glad the Judges did not give the prize to a merely overcrowded collection, but to one very meritorious, and having quite quantity and diversity enough to bring it within the true meaning of the schedule.

The vegetables which we remarked as particularly good were the Cauliflowers, Red Cabbages, Garlic, Celery, Cucumber (Holder's Dreadnought, a fine seedling of Mr. Holder's, which looks very promising, somewhat of the type of Blue Gown, but rougher in the spine, apparently a quick grower), Beet, Parsnips, Tomatoes, Mushrooms, Vegetable Marrows, and Custard ditto. The Potatoes were not remarkably good, at least we thought both the Early Rose and Red-skinned Flourball coarse though large. Paterson's Victoria was good. Amongst other vegetables in this collection we saw that useless introduction, the *Raphanus caudatus*, or Rat-tailed Radish: we had sincerely hoped we had seen the last of it, but we suppose in a collection for miscellaneous varieties some persons might be found to admire it. The second prize went to Mr. John Turk, Railway Cottage. In this collection the Onions were especially fine. We could have wished for better nomenclature; in fact, this was a desideratum in many cases both in fruit and vegetables, the names often carelessly written and badly spelt, on small torn pieces of paper. In this collection Nonpareil Cabbages were labelled as Non-perial, Capsicums as Capsicums, &c. Amongst the fruit, especially among the Apples, we noticed not merely bad spelling, but many dishes altogether incorrectly named. This, no doubt, is to a certain degree unavoidable, but correct nomenclature adds very much to the value of an exhibition, as many persons like to correct the names of their own fruits and vegetables by those exhibited at large shows, and we think it would be a good thing if competent judges were, after the awards are given, to correct any undoubted mistakes. The third prize in collections of miscellaneous vegetables went to Mr. R. Gilbert, of Burghley, from the Marquis of Exeter's garden. This collection was very nicely staged, the different kinds of vegetables being separated by the longer-growing kinds, such as Cucumbers, Celery, &c. Onions, Nuneham and Giant Rocca, very fine; Potatoes, Beaconsfield and Premier, good; Carrots, James's Intermediate, very good; Custard and Moore's Cream Marrow, Canadian Wonder Bean, and Veitch's Giant Cauliflower, all good. There were seventeen entries for the large collections of vegetables, but there were several absentees—so much so, that a large collection of French Gladioli was staged in the empty space, and though not to be compared with the English-grown Gladioli shown by Mr. Kelway, yet considering the season is nearly over for French Gladioli, there were many very interesting flowers sent.

The collections of fifteen kinds of vegetables followed next. Here the premier prize was very easily taken by a remarkably fine assortment of vegetables exhibited by Mr. G. Miles, gardener to Lord Carington, showing that Mr. Miles not only excels in forced fruit, as the reports of the South Kensington fruit shows so often remind us, but that he equally excels in that important department, vegetables. His collection comprised some wonderful specimens of Student Parsnip and Altrincham Carrot; also very fine Early White Naples Onion; Peas, Laxton's Superlative, no doubt a fine exhibition sort, and which, we are informed, is also good for the table, though in our opinion many of the larger-podded Peas are somewhat deficient in flavour: Celery, Leicester Red; Cauliflower, Veitch's; Cucumber, Blue Gown, were also good. The only fault we were inclined to find was with the Prince of Wales Potatoes, which seemed too coarse for the table. We may remark that this seemed to us too general a fault with the Potatoes in the collections of vegetables; with some few exceptions size seemed to have been sought for at the expense of quality. The other vegetables shown to complete Mr. Miles's number were Tomato Trophy, Artichokes, Vegetable Marrows, Brussels Sprouts, Yellow Malta Turnip, and Broad Beans, which were not over-good. The second and third prizes were taken respectively by Mr. John Holder, of Cheltenham, and Messrs. Copeland & Doran, Stretford. Out of nineteen entries there were thirteen that came forward.

In Class 77, for ten varieties of vegetables, there were thirty-one entries, and nearly all who made them came forward. The first prize was awarded to Messrs. Snowden & Son, Thirsk, and we hardly ever remember to have seen a more uniformly good assortment. We give the names. Carrot Long Surrey, Cucumber Marquis of Lorne, two of the best of the kind we ever saw; Cauliflower Veitch's Giant, Celery Wright's Grove, Tomatoes Trophy, Onions Nuneham, Beans Newington Wonder, very good; Peas Snowden's Nonsuch, a good variety; Marrows, Vegetable Cream; and last, but not least, Potatoes, Lapstone, the best dish of Potatoes in this tent. The second and third prizes again fell, as in the last class, to Mr. John Holder and Messrs. Copeland; but we need not enter into details of the varieties shown.

In Class 78, for six varieties of vegetables, there were again thirty-one entries, with very few absentees. Mr. Miles was again first, as he was in the fifteens; Sir P. Duncombe second; W. Skinner, Esq., Cheltenham, third. Mr. Miles showed nearly the same selection of vegetables as to sorts as in his fifteen, with the exception of the Potatoes, which, to our mind, were better than those in the fifteen, being fine samples of Ashleaf.

We pass over for the present Classes 79 and 80 for twenty-four and twelve varieties of Potatoes, as they were, as before said, in a separate tent. In the next, Class 81, for two Cauliflowers, there was a large entry, but the prize was easily won by Mr. Hunter, gardener to the Earl of Durham—another instance of a gardener successful both in fruit and vegetables.

In Cabbages, white, the prize was won by two huge specimens, which would have required nothing much less than a twenty-gallon copper to have boiled them in, and two cooks to have taken them out when boiled. The competition for Savoys was close, and the Judges must have had some difficulty in coming to their awards. The same may be said, too, with regard both to spring-sown Onions, for which there were nearly fifty entries, and for Tripoli, in which Mr. W. Skinner, of Cheltenham, gardener to H. Askall, Esq., carried off the prize with Large Red. For Turnips, six white and six yellow, there was a very pretty dish shown by Mr. A. Fallows, of Stretford, very small and very clean, to which was awarded the first prize, the second falling to Mr. J. Rylands, Warrington.

There was a remarkably good collection of Carrots shown, the first prize being adjudged to Mr. E. Smith, Cheltenham, for a short but even Carrot, very clean in the skin, called Nantes; the second to Mr. J. Turk for Long Red. The whole class was good. We cannot say the same for the next class, the Peas, for though there were about sixty entries, yet there were none of any particular merit; still it is somewhat late for good Peas.

The Dwarf Kidney Beans were good, the first prize being carried off by Mr. Lumsden, gardener to Lady M. Nesbit Hamilton, Sleaford. In twenty-four pods of Scarlet Runners there was also a large competition.

The Vegetable Marrows comprised, as usual, every size and quality from the huge Pumpkin Squash to the Vegetable Cream. This is always a difficult class to adjudge, and the Judges, wisely in our opinion, gave the prize to some medium-sized evenly-grown Marrows fit for present use.

For the brace of Cucumbers we may almost repeat our remarks. These were shown in every size and every quality—long and short, rough and smooth, dark green and light green: there were Cucumbers out of the fifty-three entries which would suit every taste. The first prize was won by a very smooth and round, and evenly-grown pair, shown by Mr. Fallows, of Stretford. Mr. John Heywood, of Stretford, was second; and Messrs. Copeland & Doran, of Stretford, fourth, and, oddly enough, these were the only exhibitors from Stretford, and each won a prize. Are the good people of Stretford particularly fond of salmon?

Classes 91 and 95, for Lettuces, were not good. In Class 96, for Celery, Red; and 97, for Celery, White, the exhibits were good and the competition close. The other exhibits of Gourds, Beet, and Leeks do not require much notice.

We will now turn to the Potato tent, which to our mind was the most interesting feature in the vegetable exhibition. Lovers of the æsthetic art might say there was not much to please the eye in a large tent about 100 feet by 50, devoted entirely to Potatoes in dishes, there being no less than 861 dishes in competition, and one hundred varieties shown by Mr. Harrison, of Leicester, not for competition; but unless all the dishes were cooked, there is no better way of judging the merits of Potatoes than by comparing the different qualities of sorts as shown from different localities. In Class 79, for twenty-four varieties of Potatoes, eight in a dish, there were thirty-two entries, but nine of them did not exhibit. The first prize was carried off by Lady Mary Hamilton, of Sleaford, gardener Mr. Lumsden. Second by Mr. Peter MacKinlay, Beckenham. Third by Mr. Richard Dean, of Ealing. The winning collection comprised the following:—Harrison's Red-skinned Flourball, coarse; Early Rose, Bresee's Prolific and Peerless, both coarse; Callao, a deep red variety; King of the Earlies, The Bloomer; Lapstone, good; Climax; Ashtop Fluke, very fine and good; Dunbar Regent, a fine-looking Potato; Carter's Maincrop, a fine-looking red variety, but we are informed of questionable quality; Victoria Paterson's, good; Prizetaker, fine; Paxton's Wonder, Prince Teek, Milky White, Willard, a very coarse-looking red; Jackson's Seedling, promising; Sandringham Kidney, Veitch's Improved Ashleaf, Dorrington Hero, the three last much of the same class of Potato. The above lot of Potatoes were on the whole fine, but seemed deficient in quality, especially the Americans, which were very full of eyes. In the second-prize lot, by Mr. Peter MacKinlay, of Beckenham, were Prince of Wales, fine; Late Rose, coarse; Hayes Kidney; Early Rose, rough; Bresee's Peerless, fine-looking; Salmon Kidney, good; Hundredfold, Climax, Bresee's Prolific, Ashtop Fluke, Duncan Seedling, red and coarse; Pioneer, a white Kidney; Early Emperor, red; Headley Nonpareil, showing signs of disease; King of the Flukes, and King, these were in our opinion quite identical, neither of them being King of the Flukes; Lady Parrot, Royal Albert, Lapstone, good; Wheeler's Milky White, Sextus, a very good-looking Potato, Parkes' Seedling, Reston Pippin, diseased; and Champion. The third prize was won by Mr. R. Dean, of Ealing, with a very interesting collection, comprising some of Mr. Fenn's seedlings, and some very high-quality Potatoes,

decidedly better in point of quality than the first two collections, though not so large. Among the best, Woodstock Kidney, Seedling of 1871, Fenn, English Rose, Rector of Woodstock, Onwards, all seedlings of Mr. Fenn's, with remarkably fine skins and small eyes. There was also a promising seedling of Mr. Dean's called Cottager's Red. Waterloo, Lapstone, and Yorkshire Hero were also very fine, though we are inclined to think Yorkshire Hero only an improved Lapstone, and doubt if it is really a variety, but only a selection. The worst two Potatoes in this collection were Scotch Blue and Surprise. Amongst others, King of the Flukes was the best we have ever seen of this sort, and a kind called Belgian Kidney seemed nearly identical with Salmon Kidney. Are they synonymous?

In the class for twelve varieties there were forty entries, of which there were twenty-six exhibited. Here the first prize was easily carried off by Mr. Dean, and we never remember to have seen a better quality of Potatoes exhibited. The varieties were a selection from those shown in the twenty-four, and we need not particularise, except to notice the very fine examples of Rector of Woodstock, Onwards, and Yorkshire Hero. The second prize was again adjudged to Mr. Peter MacKinlay for a collection which we liked better than his twenty-four, as some of the coarser ones were eliminated.

The collection of a hundred varieties of Potatoes shown by Messrs. Harrison & Sons, Leicester, was very interesting, but our space will not permit us to particularise further. Of one thing we were convinced, that Hundredfold is only an old variety, called Gleeson's Late, come up again under a new name. The two were shown near together in this collection, and we could not find any difference whatever. This Exhibition has more than ever confirmed us in our opinion that we need not go to America for new sorts of Potatoes, nearly every kind of American Potato exhibited being coarse, with deep-set eyes, or with a great number of protuberant eyes on the flat part of the Potato. They may be great croppers, but unless they are far better than they look we are gaining in quantity at the expense of quality; and if immunity from disease is aimed at, owing to stronger and more vigorous growth, we can only say that almost the first specimens of thoroughly diseased Potatoes we have seen this year were Red-skinned Flourball, which were pronounced proof against disease, and we do not believe any Potato has ever or will ever achieve the hoped-for pedestal of fame of being able to resist the insidious attacks of the "Peronospora infestans," and at all events we seem at present to be stepping in the wrong direction when the exhibition tables are filled with such sorts as Early and Late Rose, &c.

We must not omit honourable mention of a very large and fine assortment of vegetables shown by the Loughborough Horticultural Society in one of Mr. Perry, of Banbury's, greenhouses. We especially noticed the Cauliflowers, Veitch's Antuan Giant being very fine. The Onions were also very good, likewise the Potatoes. We append the following particulars furnished to us by Mr. Pickworth:—"There were thirty-nine different kinds of vegetables, all grown within a radius of three miles of Loughborough, and almost exclusively the productions of amateurs and artisans. As nearly as could be ascertained, the weight exceeded a ton. They were staged by Messrs. Smith, Hickling, and Mountney, of Loughborough; Mr. McLean, gardener to Col. Packe, of Prestwold Hall; and Mr. Lane, gardener to W. P. Herrick, Esq., of Beau Manor Park, President of the Loughborough Horticultural Society. Regret was felt at the small competition in this class, as the Loughborough Society sent their collection more to measure their strength than for pecuniary compensation. The expense incurred exceeded £20, all of which was met by the contributors, the Society's funds not being interfered with."

CUT FLOWERS.

Although fruit and vegetables formed the main feature of this grand autumnal Exhibition, the finest that has ever been held, yet with that wisdom which has for years marked the proceedings of the Manchester Botanical Society, flowers and plants formed by no means a contemptible portion of it. Liberal prizes were offered, and the result was the gathering together a fine collection of autumn flowers. Foremost amongst them, as acknowledged on all hands, was my favourite the Gladiolus. Mr. Kelway has many a time exhibited collections of his fine seedlings, but he never had such an opportunity of setting forth their excellencies as on this occasion. At one end of the avenue there was a mound, and the front of this formed a crescent; into this Mr. Kelway had inserted several hundreds of his seedlings at about a foot apart, and covered the whole surface with lawn mowings, and nothing could possibly be more effective, as tier above tier they rose, each standing separate, not one hiding the other, and many of them of singular beauty and excellence; while on the stands for competition he had placed some of his very finest. In the class for twenty-four he was, of course, first with Meyerbeer, Virgile, and the remainder his own seedlings, foremost amongst them being Xerxes, Helioid, Dunbar, Protherus, Helle, Lady Bridport, J. Thompson, International,

Una, Rosa, Zeta, and Canova. Mr. Witherspoon, Chester-le-Street, was a very creditable second, and I would draw especial attention to his collection for several reasons. In the first place, his garden is 2½ yards square, and yet he managed to show in a collection, and in twenty-fours, besides showing at Bishop Auckland last week; in the second place, with the exception of three flowers, his twenty-four were all Mr. Banks's seedlings bought at 20s. per 100; and in the third place, he had introduced the innovation of putting in Asparagus foliage to hide the naked stems, and I am free to confess the effect was good. I think he deserves immense credit for the zeal he has displayed in Gladiolus culture, and Mr. Banks will be surprised at the position his rejected seedlings have taken in Mr. Witherspoon's hands. In the class for twelves, Mr. Kewley put forth his strength, and exhibited some magnificent flowers, all, with the exception of one, his own seedlings. He had Orange Boven with sixteen flowers open, Orvil, Amarus, Mrs. Reynolds, and others, seven of them being awarded certificates. Lord Hawke was second with some grandly finished flowers—Le Titien, Lacépède, Horace Vernet (magnificent), Marie Stuart, Legouvé, Le Phare, Norma, Madame Furtado, Eloise, Margarita, and Eugene Scribe.

Next in grandeur to the Gladiolus—probably preferred by some—were the Hollyhocks, and here Lord Hawke was *facile princeps*. Probably twelve such spikes were never before exhibited, and with one or two exceptions they were all his own seedlings. Midnight and Leviathan were the exceptions. The seedlings were Vanguard, Golden Eagle, Excelsior, Mauve King, Oridamme, Eleanor, Isabel, Blanche, Talisman, and Lilae Rival. The second prize was taken by Mr. Harrison, of Darlington; and the third by Mr. H. Minchin, Hook Norton. In twenty-four cut blooms the same exhibitors occupied the same position. Lord Hawke's flowers were Red Cross Knight, Phryne, Harold, Walden Queen, Golden Eagle, Mr. Oates, Conquest, Goldfinder, Walden Princess, Seedling Blush, Talisman, Blanche, Majestic, Exhibitor, Formosa, Vanguard, &c. In six spikes Lord Hawke was again first, and Mr. Harrison second.

Dahlias were well exhibited by Messrs. Clark, Walker, &c. The best thirty-six comprised Sir Greville Smythe, Acme of Perfection, Guardian, S. Naylor, Thomas Hobbs, Ne Plus Ultra, In Memoriam, J. N. Keynes, Mrs. Boston, Chairman, Thomas Goodwin, Mrs. Dodds, Fanny Wyatt, Hebe, Vice-President, Criterion, Toison d'Or, Pearl of Beauty, John Standish, James Bennett, Chancellor, Annie Neville, Favourite, Lady Gladys Herbert, Baron Taunton, Yellow Boy, Delicata, Peri, James Cocker, and W. P. Laird. These were exhibited by Mr. Clark, of Leeds; and Mr. Walker, of Thame, was a good second. The two great competitors of late years, having retired—Mr. Keynes, of Salisbury, and Mr. May, of Bedale, the field is now open for other competitors.

It was not to be expected that Roses would be very good, nevertheless Mr. Prince, of Oxford, had a very fine box from his cultivated Briar stock, which were exceedingly good for the season. They were Mons. Laurent, Dr. André, La France, Sénateur Vaisse, Madame Lefebvre Bernard, Charles Lefebvre, Paul Neron, Madame de Ligneris, Comtesse d'Oxford, Annie Wood, Clémence Raoux, Madame Victor Verdier, John Hopper, Louis Van Houtte, Baron Haussman, Alfred Colomb, Emilie Haushburg, and François Michelon. He had also a most wonderful box of Paul Neron.

Asters were also well exhibited, and Messrs. Cole's collection of cut flowers was exceedingly fine, comprising fine bunches of *Masa coccinea*, *Allamanda cathartica*, *Odonoglossum grande*, *Erica austriana*, *Miltonia spectabilis*, *Isora Williamsii*, *Stephanotis floribunda*, *Statice profusa*, *Erica amula*, *Stanhopea grandiflora*, *Lapageria rosea*, *Aërides suavisimum*, *Erica Jackmannii*, &c.

BOUQUETS, &c.

There was in these classes a very good competition, and exceedingly well arranged were some of those which obtained the prizes. The first prize for wedding bouquets was taken by Mr. F. Perkins, Leamington, for one a little too large, perhaps, but very beautiful, in which *Pancretium illyricum* had been admirably utilised, with white *Camellias*, &c. Mr. Turner, of Liverpool, was second, and Mr. Yates, of Sale, third. The latter, however, was first for three ball bouquets, the most exquisitely tasteful I have, I think, ever seen; there was such delicate harmonising of colour, such absence of vulgarity or lumpiness, that they were really deserving of all praise. The same gentleman took first for three stands for the dinner-table, faulty in some respects—hiding the guests from one another—but yet arranged with so much elegance that it was necessary to overlook these defects. Mr. Cypher was second with three of the stands he generally uses; they were, of course, well arranged, but there was somewhat of heaviness at the base, and the flowers had been a little too long cut. Mr. Turner was third. Mr. Yates was the only exhibitor of a stand for the drawing-room; it was, however, marked by his usual good taste. In the plant cases for drawing-rooms, Mr. Pforsdorff, from Paris, took first with a case containing a collection of dwarf succulents, very lively and very effective. I have, I fear, outrun my space,

but I cannot conclude without bearing my humble testimony to the excellence of the arrangements, or without tendering my thanks to Mr. Findlay for the courtesy with which we were treated, and the manner in which all our wants were so admirably provided for.—D., Deal.

THE DINNER.

As already stated in our introductory remarks, the dinner was held on the evening of the opening day in the Hulme Town Hall. The Earl of Derby presided, supported by the Mayors of Manchester and Salford. After the customary loyal toasts

The CHAIRMAN (Lord Derby), remarked: I need not tell you that ours is not a political gathering [hear]. I need hardly add that it is not a gathering of a very formal or ceremonial kind [hear, hear], and I hope that fact will plead my excuse when, in compliance with the suggestions of those who are responsible for the arrangements of this evening, I pass over various toasts which, on a more solemn occasion, it is usual and might have been desirable to propose [hear, hear]. I do not think the members of the House of Lords and the House of Commons, of the army and navy, and of the clergy [hear, hear], will feel themselves particularly aggrieved because they are not called upon severally and collectively to answer for their healths [hear, hear]. If they are I beg to say in anticipation that the omission does not imply any disrespect to them [hear, hear]. I come, therefore, at once to that which, upon these occasions, is called the toast of the evening; and before I sit down I shall ask you to drink "Prosperity to the Manchester Botanical and Horticultural Society" [hear, hear]. I can propose that toast the more briefly because that prosperity which I wish for the Society is not now, as it might have been years ago, a thing to be wished and hoped for, but hardly to be expected. It has in a very great degree become, and it is becoming in a still greater degree, an accomplished fact [applause]. The Society has passed through many troubles, and undergone many difficulties—as most of us, whether individuals or institutions, do in the course of our days [laughter]; but I think that we see land at last, and that there is now before us a reasonable security that we shall not come to failure in the long run [hear, hear]. I dare say there may be many people to whom the idea of establishing a botanical society or holding a horticultural exhibition in the very heart of the Manchester district may seem—of course I am speaking of people a long way off—like an attempt to grow Grapes in Norway, or set up a cotton mill in a West India sugar island [laughter], for of course we must allow that the presence within a few miles of us of something like a million of population, nearly all of whom are engaged in trading or manufacturing pursuits, with an accompaniment of more machinery and probably more smoke than is to be found elsewhere in the same compass anywhere in these islands—that these are not circumstances which would promise well for the success of botanical or horticultural displays. But there are not many things impossible to human energy [hear, hear]. That is a doctrine which is pretty thoroughly impressed upon us in Lancashire, and just in proportion as the display and as the preservation of rare and beautiful specimens of horticultural skill is rendered difficult for us by the local circumstances of our position, just in the same proportion those who live in this neighbourhood are the better prepared to enjoy sights which contrast in so striking and marked a manner with those which are habitually before our eyes [applause]. I once heard a friend of mine say that there was one advantage of living in a great town, and that was that you thoroughly appreciated the country [laughter], which, he contended, rural residents never did or could do, because, being used to it, they took all the beauty and all the enjoyment of what was around them as simply a matter of course. Now, I do not go so far as that; but I think we may see in this case the operation of that universal law of nature which tends, as far as it goes, to lessen the differences of human conditions—the law, I mean, by which all advantages and all sources of enjoyment are keenly appreciated, just in the degree in which they are obtained with difficulty, and in which they are rarely available. Well, now, gentlemen, you will not expect me to argue about or to explain the general advantage which arises from exhibitions such as that which we have witnessed this morning. There are some things which are too plain for argument, and which illustration can only serve to make less clear. I suppose we may all take it for granted that the English people, in these days, are coming more and more to be inhabitants of great towns. That is, as I suppose, a necessary condition of our present industrial existence. Under the system of machinery now only beginning to be introduced, rural labour will be performed with fewer hands; the rural population, if it does not diminish, will probably, at any rate, not increase; and co-incidental with that state of things you will have the continual expansion of our great towns with a perpetual increase of manufactures and of trade; and you have, in addition, the creation of new urban communities, such as that of Barrow, in the north of this county—a process which is proceeding with a rapidity which seems rather to belong to a new

than to a very old country. It is, of course, open to us all to have an opinion on the subject whether that change is or is not an unmixed gain. For my own part I think that it involves some disadvantages of a very obvious kind both in a social and in a sanitary point of view; but whether we like it or not, that change is inevitable; and we have only to accept it, and to make the best of it we can [hear, hear]. If, for the majority of us, life within a town has become inevitable, what we have to do is to try to meet by artificial means the requirements of a more artificial existence [applause]. If we are shut out from the wild scenes of nature, or at least if we are compelled to go to longer and longer distances in order to find them, we may in some degree compensate ourselves by assembling, in a place like this, natural creations more choice, more beautiful, and more varied than nature unaided will ever show you within the limits of any country [applause]. We can make our selection out of all countries and all climates, and we can show to the natives of India and to the natives of tropical America, in what they would probably consider—I do not call it so—a damp and smoky suburb of a Lancashire town, a larger number of their own most exquisite products than any of them would probably have seen in their own countries in the whole course of their lives [hear, hear]; and to do this as far as we are able to do it is not, as I look at the matter, a mere *tour de force*; it is not a mere display of man's power over nature; it is a real, although it may be a comparatively humble contribution to the cause of general refinement and civilisation [applause]. A man need not be a fanatical worshipper of art in any one of its forms to believe, as I do believe, that no one could have a thorough appreciation of natural or artistic beauty, without being better for the existence of that feeling in his mind [applause]. And I take it that of all forms in which that feeling exhibits itself, there is none which comes so home to an average Englishman as that of a garden [hear, hear]. We are by habit, by tradition, and by temperament, an out-door people [hear, hear]. We like museums and picture galleries very well; but if we are to tell the truth we like our gardens, our forests, our commons, our parks, and our moors a great deal better [applause]. Even in crowded lodgings and in dirty streets you will see the evidence of that feeling. Where nothing better can be got at, you will see a few flower pots outside a window [hear, hear]; and the same instinct which puts these unfortunate flowers in that situation produces also an exhibition such as that which we have seen to-day [hear, hear]. I think, and I hope, that the time is not far off when every large town, and almost every small town also, will have its public garden, and will consider that having a public garden is simply a recognised institution and almost a necessity [hear, hear].

Foreigners—Frenchmen and Germans—are before us in that respect. Now I have often noticed that it is a way we have to be a little behindhand in matters of social improvement, and then we come up all of a sudden, and with a rush make up for lost time in a very few years [applause and laughter]. Well, I won't dwell here, because I am talking about what you know better than I do ["go on"] upon the mere utilitarian consideration of its being a desirable object to obtain an abundant and cheap supply both of vegetables and fruit. I am told by those who are more able to speak authoritatively than I can, that both might be much more abundant and cheaper than they are if horticulture were more generally studied than it is [hear, hear]. And obviously the art which aims to extract the very most out of a limited quantity of land by the application of scientific skill and of human and mechanical labour, is an art peculiarly suited to our conditions; labour, scientific knowledge, and mechanical skill being abundant, and land, as we know, being rather limited [hear, hear]. Of course I shall not speak of the increase in the supply of fruit as an important object, if you look at it merely as a contribution to the comfort and luxury of those who have many comforts and luxuries at their command; but there is another side to that question also. Go to any hospital and ask any doctor, and he will tell you how much relief of suffering might be obtained, and how much real good might be done, if, for instance, a cheap and abundant supply of Grapes were at his command [hear, hear]. So much for the general subject. You will expect me, probably, to say a word or two as to the position of the Society, in whose interest and by whose agency the exhibition of this day has been got up. The Manchester Botanical and Horticultural Society has reached a very respectable time of life. It was born in 1824. For many years it had a prosperous existence, I am told. In 1857 it began to find itself in that position in which many enterprising and energetic individuals have had the misfortune to be placed. The funds ran rather short, and some attempts at holding exhibitions on a large scale were not so successful as they deserved to be; and I believe between the date of 1857 and 1862 there were serious doubts whether it would be possible to continue the Society permanently. Then came a crisis; various efforts were made, I need not trouble you with the details, especially as I knew nothing about them a week ago, and shall probably remember nothing about them a week hence [laughter]; but the turn, as I am instructed, came in the year 1867. At that time it was

determined to adopt a bolder policy, and to hold a general exhibition, intended for the whole country, and not merely for a limited locality. That bold experiment having been tried, it completely verified the old popular saying that there is nothing so expensive as being poor, and that nothing succeeds like success [applause]. I am instructed that in these exhibitions the Society invested a great deal of capital, when perhaps it had not too much to spare. The result was triumphant. Their money came back to them with ample interest. The first large exhibition which was held produced a profit of something like £500; and in the last six years the result of following that policy has been that the debt, which at its maximum stood at £9000, has been reduced to £6500 [applause]. Well, contemporaneously with that, very great improvements have been made in the gardens, and especially in the increase and improvement of those houses which are intended for delicate tropical plants. Last year, as my brief has it, the receipts of the Society were £4000, and the expenditure was about £3500, leaving £500 to the good. The present exhibition is the first which has been held in the autumn, and I think it differs in various respects from its predecessors. I am told that the entries amount to 2400, a number which has never been reached before. I am assured by those who ought to know, that from a horticultural point of view this will be quite the most important exhibition which has ever been held in the northern parts of England [applause]. I suppose I ought to add, what I mentioned this forenoon, that about £5000 has been given in prizes in the course of the last six years. That, I need not say, is very great encouragement and a great stimulus to horticultural art in all its branches, and not only has it been a great encouragement to horticulture generally, but that large and liberal expenditure has resulted in great benefit to the Society itself [applause]. Now, I have only one word to add in conclusion. Everybody has got his crotchet, and I suppose I have mine. I have no great faith in any thing or any body, individual or institution, really getting on as he or it ought to do while he or it is burdened with a millstone of debt. I told you that the burden of debt upon this institution had been diminished, but it is still considerable. I have not spoken to any member of the Society upon the subject; and, therefore, in what I say I alone am responsible for what may be a misplaced suggestion. I don't at all know what the Council or the members of this Society would say if it were proposed to them that an appeal should be made to those who are interested in this matter to put them upon a thoroughly sound financial footing. I can only say, expressing my own opinion, that I think—considering their public character—considering that no member of the Society desires the slightest financial advantage from anything that is done in that way—and considering the useful nature of the work that they do, they might fairly and honourably accept any help that is offered to them in that way for the interest of the public and for the cause in which they are working. Now, I should not have thought it was a difficult thing to find twenty or thirty people in Manchester to each of whom the parting with £100 note would be an operation so familiar and so customary that they would hardly know they had done it [laughter]. I even venture to think that we have a few such in this room, and the practical conclusion to which I am leading is this—that if we are really interested, as I for one am, in the future and in the work of this Society, I think it is quite worth our while to consider whether we may not do something more effectual and more substantial in that line than merely making speeches about it or cheering the speeches which are made. I won't presume to pursue that subject further. I propose to you "Prosperity to the Manchester Botanical and Horticultural Society" [applause].

Dr. J. WATTS (Chairman of the Council) returned thanks.

The CHAIRMAN said, before proceeding to other business, he wished to intimate that the hint which he had ventured to throw out had so far borne fruit that six gentlemen had offered 100 guineas each if the debt of £6500 was paid off, and, in humble imitation of them, he offered himself as the seventh [applause]. He then proposed the toast of "The Exhibitors."

After the health of the Judges and other toasts, the meeting terminated.

CRYSTAL PALACE FRUIT AND GLADIOLUS SHOW.

THIS was held on the 6th and 8th inst., and although not so extensive as the autumn shows of years gone by, it was, nevertheless, an excellent and effective display, and welcome as supplying the long-felt want of a metropolitan autumn fruit show. Had the date been further on in the season, no doubt the entries would have been much more numerous; and another drawback was that the Show commenced on the last day of the Manchester Exhibition, so that it was impossible for exhibitors at the latter to place their productions in competition at the Crystal Palace. The setting-up of the fruit and flowers was very good, and the arrangements made by Mr. Wilson, the courteous Superintendent of Shows, were admirably carried out.

The best collection of fruit came from Mr. W. Coleman, gardener to Earl Somers, Eastnor Castle, Leebury, and consisted of magnificent Black Hamburg Grapes, very large in bunch, handsome in shape, not large in berry, but very even; and beautiful in colour and bloom; fine Muscat of Alexandria, a Queen Pine, Golden Gem Melon, Royal George Peaches, Pitmaston Orange Nectarines, Brown Turkey Figs, and Jefferson Plums. Mr. F. Deuxberry, gardener to the Earl of Darnley, Cobham Hall, was second.

In Pine Apples, the best three fruits of any variety came from Mr. H. Plummer, gardener to R. Thornton, Esq., Cannon Hill Park, Merton, the variety being Smooth-leaved Cayenne. Three fine Queens, not quite ripe, from Mr. C. Harris, gardener to C. Bailey, Esq., Llanfoist, Abergavenny, were second; and Mr. Eveleigh, gardener to R. W. Thornton, Esq., Frenowle, Sidmouth, was third with Black Prince not quite ripe, Antigua, and Smooth-leaved Cayenne. For a single fruit of any variety, Mr. C. Harris was first with an excellent Queen; Mr. M. Rochford, Page Green, being second; and Mr. T. Page, gardener to W. Leaf, Esq., Streatham Common, third.

In the class for three bunches of black Grapes, Mr. Coleman was first with splendid Black Hamburgs; Mr. Holliday, gardener to J. Norris, Esq., Bletchingley, second with good Muscat Hamburgs; and Mr. W. Gammon, gardener to C. Boosey, Esq., Bickley Park, third with Alicante.

For three bunches of white Grapes, Mr. Coleman was again first with large, well-ripened Muscat of Alexandria; Messrs. Lane & Son, Berkhamstead, second with the same kind, but not so ripe; and Mr. Cole, gardener to J. S. Budgett, Esq., Ealing Park, third. Mr. Gammon also sent good bunches.

For the largest bunch of any variety, Mr. Bones, gardener to D. McIntosh, Esq., Havering Park, Romford, was first with Black Hamburg, weighing 6½ lbs., large in berry, but red. Mr. Coleman was second with Black Hamburg, finely coloured, weighing 4 lbs. 10 ozs.; and Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, third with Mrs. Pince's Black Muscat, very meritorious, of the same weight, large in berry.

Of Peaches and Nectarines, there was a good display. Of the former the principal varieties shown were Royal George, Noblesse, Barrington, Walburton Admirable, and Late Admirable; of the latter *Violette Hâtive*, Pitmaston Pine Apple, Pitmaston Orange, and Downton. The first prize for Peaches was taken by Mr. Jones, of the Royal Gardens, Frogmore, with Barrington, very large and fine; the second by Mr. King, gardener to R. Loder, Esq., Slangham, Sussex, with Royal George, large and finely coloured; and the third by Mr. Joseph Smith, gardener to J. Swift, Esq., Eastbourne, with Late Admirable, very fine. Mr. Tillery, gardener to the Duke of Portland, Welbeck, sent large fruit of Walburton Admirable, and there were several good dishes of Royal George. For Nectarines, Mr. King, gardener to R. Loder, Esq., was first with fine examples of *Violette Hâtive*; the second place was taken by Mr. T. Frost, Bower Nursery, Maidstone, with richly-coloured fruit of Pitmaston Pine Apple; Mr. J. Smith, gardener to J. Swift, Esq., Eastbourne, being third with Stanwick.

Of Melons there was a good show. The best Green-fleshed was Hybrid Cashmere, from Mr. Burnett, gardener to Mrs. Hope, The Deepdene, Dorking; the second best, Beechwood, from Mr. Dedman, Bromley; and Mr. Holliday came in third. The other kinds shown in this class were chiefly Heckfield Hybrid, Cox's Golden Gem, Golden Queen, and Colston Bassett. For Scarlet-fleshed, Mr. Shaw, gardener to H. R. Price, Esq., Epsom, was first; Mr. Richbell, Tadworth, second; and Mr. Cole third.

Figs were few. Mr. Chisholm, Boughton Place, Maidstone, was first with Brunswick, large; Mr. J. Smith, gardener to J. Swift, Esq., second with Brown Ichia; and Mr. G. Munn, gardener to Mrs. Mecking, Richings Park, Slough, third with Brunswick.

Of Cherries about a dozen dishes were shown, and these, almost without exception, Morellos, and very fine. Mr. Sage, gardener to Earl Brownlow, Ashridge, was first, Mr. Deuxberry second, and Mr. Holder, gardener to W. Balston, Esq., third.

Plums were neither so numerous nor so fine as we have seen them at the autumn shows of former years. The best three dishes consisted of fine fruit of Victoria, Transparent Gage, and Jefferson from Mr. Douglas. Mr. Sage was an excellent second with Kirke's, Jefferson, and Goliath; Mr. J. Bolton, gardener to W. Spottiswoode, Esq., Sevenoaks, third, and Mr. Holder fourth.

The Dessert Apples made a fair show, but generally they were rather small. Mr. Holder was first for four dishes with Kerry Pippin, Cox's Orange Pippin, Devonshire Quarrenden, and Jefferson, a pretty red-streaked variety. The second position was taken by Mr. Jones, gardener to E. Purser, Esq., Wallington, with Ribston Pippin, Devonshire Quarrenden, Cox's Orange Pippin, and Nonesuch. Third came Mr. Jones, Frogmore, with Red Astrachan, Early Nonesuch, Peach, and Fair Maid of Windsor, a seedling, the fruit of a pyramidal shape, pale greenish yellow, flushed and marked with crimson next the sun, and with firm flesh. Mr. Frost, Maidstone, occupied the fourth place. R. Webb, Esq., Calcot, sent, among others, splen-

didly coloured fruit of the Red Astrachan, also a highly-coloured seedling called The Shah.

Kitchen Apples were fairly represented both as regards size and numbers. The best four dishes were shown by Mr. Holder, and consisted of Lord Suffield, Lord Derby, Blenheim Pippin, and Nelson's Glory, all of large size. Second came Mr. H. Prexler, 58, Effra Parade, Brixton, with Blenheim Pippin fine, Alexander, Manks Codlin, and Yorkshire Greening. The third and fourth prizes went to Mr. Jones, Frogmore, and Mr. Webb. Pears were few and generally not fine. Mr. C. Tivey, gardener to P. Gossett, Esq., St. Saviour's, Jersey, was first for three dishes with excellent examples of White Doyenné, Beurré d'Amanlis, and Louise Bonne. Mr. Holder was second, and Mr. Douglas third with Williams's Bon Chrétien and Beurré d'Amanlis, very good. A fourth prize went to Mr. Frost.

For the heaviest dish of twelve Mr. Tivey was again first with Beurré d'Amanlis, weighing 8½ lbs.; Mr. Whitaker, gardener to S. Williams, Esq., Putney, being second with Williams's Bon Chrétien, weighing 6 lbs. Mr. O. Goldsmith, gardener to Sir W. Farquhar, Bart., Polesden Lacey, was third with Catillac. Neither the last nor the other dishes were remarkable for weight.

Williams's Bon Chrétien, Jargonelle, and Louise Bonne of Jersey were almost the only kinds shown for flavour, except the first-prize dish, which was Beurré d'Amanlis from Mr. Tivey. Mr. Holder and Mr. Frost took the remaining honours with Williams's Bon Chrétien.

Of Vines in pots only two collections of four were shown; the best came from Messrs. Lane, and consisted of Alicante and Black Hamburg bearing freely. The second prize was awarded to Mr. Foreman, gardener to E. C. Nicholson, Esq., Herne Hill.

Among miscellaneous fruit, first we must notice a seedling black Grape, called The Artist, shown by Harrison Weir, Esq., Weirleigh, Brenchley, grown in a ground viney, and which is said to be very thin-skinned and good. Being unripe the Judges could not take notice of it, but as it is seedless, though occasionally having one stone, it promises to be valuable. Extra prizes were awarded to R. Webb, Esq., for a collection of Cob Nuts and Filberts; also to Mr. Jackson, gardener to G. Leveson Gower, Esq., Titsey, Limpsfield, for a collection of fruit. Mr. W. Paul, of Waltham Cross, exhibited Waltham Cross Grape, also his Winter Muscadine; whilst from Messrs. Rivers, of Sawbridgeworth, came a collection of Apples, Pears, Peaches, and Nectarines in pots, bearing profusely.

We next come to the Gladiolus Show, and though it is now late in the season for this fine autumn flower, Messrs. Kelway, of Langport, bring out fine spikes from their large collection, whether it is late or early. In the class for thirty-six spikes, distinct, they were awarded the first prize for a stand of grand spikes, mostly seedlings of their own raising—Victoria, Phenius, brilliant crimson, maroon-purple flame; Orceus, crimson purplish flame; Scrapis reddish, with a fine crimson feather; Robert Fortune; Meyerbeer, Schimène, Theodocus, &c. Mr. J. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, was a very good second. His stand was composed mostly of seedlings and good spikes of Orphée, Virgile, Meyerbeer, Horace Vernet, one of the finest Gladioli in cultivation, Phœbus, &c. In the class for twenty-four distinct Messrs. Kelway were the only exhibitors, and had the first prize for a fine stand. Here their own seedlings were again prominent. The best of these were Pithys (first class certificate), orange scarlet with clear white throat, a grand flower; Hecamède, a fine yellow, far superior to Schiller; Valgins, a fine broadly-opened flower, rose, with distinct purple feather. Eugène Scribe was the only French flower in this stand.

In the amateurs' class for twelve spikes, distinct, Mr. J. Douglas was first with a good stand. Coral Caves, orange-scarlet feather and distinct maroon-purple throat, had a first class certificate. Orphée, Horace Vernet, Meyerbeer, Virgile, and Lacépède were fine. The Rev. H. H. Donbrain, Westwell Vicarage, Ashford, was second with a good stand; Harrison Weir, Esq., Weirleigh, Brenchley, Kent, was third.

The class for new sorts not in commerce was an interesting one. Messrs. Kelway were again first with six fine spikes. Rev. H. H. Donbrain, a noble flower, soft red with white throat pencilled reddish purple; Harrison Weir, salmon, with purplish crimson mark on the lip, and long spike; Mrs. Reynolds Hole, a fine white flower, with rosy purple throat and markings on the segments, had first-class certificates. Lord Hawke, Rev. R. Hole, and Lord Derby were also fine. Mr. J. Douglas was second. In this stand was Mabel Glass, a fine flower, ground colour bluish, heavily flamed and feathered purple, lower petals marked at the base with purple—this was also awarded a first-class certificate. Mr. W. Tillery, Welbeck Abbey, Worksop, Notts, had the third prize.

There was also a show of table decorations, in which fruit and flowers were combined. In the open as well as in the amateurs' class Mr. Hudson, Champion Hill, Camberwell, was first; Mr. Burley, Brentwood, and Mr. W. L. Duster, St. Mary's Cray, being second in the two classes respectively. For a centre-piece of Grapes and foliage the principal prize was taken by Mr. Bones.

For miscellaneous floral subjects Mr. W. Paul took the leading place with a fine collection of cut Roses, Geraniums, Gladioli, and baskets of *Euonymus flavescens* and *Remus Pelargonium*, one of the salmon-eyed section. Messrs. Carter made a great display of Gladioli; Mr. Turner had splendid stands of Dahlias, of which Ovid, noticed last week, had again a first-class certificate; and Messrs. Downie, Laird, & Laing sent a fine collection of Palms, *Dracenas*, cut *Phloxes*, Bicolor and other Geraniums, &c. Mr. Ley, Croydon, likewise contributed a collection. From Messrs. Dick Radclyffe & Co. came an effective display of Fern cases and similar adjuncts; and we may add here, though not belonging to the floral department, that Messrs. Criscuolo, Kay, and Co. exhibited very large Onions of the Tripoli varieties.

ROSE ISSUING FROM A ROSE.

I thought the enclosed would be interesting to you. It is William Griffith; the dark part in the stem was where there

was a bloom some six or eight weeks ago. The stem, as you will see, came out of the centre of the flower, and, as you will observe, produced the present flower. There were small leaves just above the dark part, the smallest next above the dark part, with another like it with three leaflets, one red like a Rose petal, the other two green; another leaf was all green. In June I had a flower on *Fulgens*, which produced a bud from

the centre of it that came out about a month after the first, but the stem from the centre of the first flower was only about 2 inches long; the second flower was quite perfect as a bloom, as was also the first.—GEORGE LEE, *Cleveland*.

[The leaves just above the dark part of the stem were very small, pinnate, and two or three of the leaflets partly rose-coloured. The stem, Rose, and leaves represented in our engraving issued from the centre of another Rose, which was borne where the letter A is placed.—Eps.]

THE CARNATION (*DIANTHUS CARYOPHYLLUS*).

The early history of this flower is shrouded in mystery, there being really no authentic record extant whereby we may be enlightened as to when or by whom the improved species was first introduced into Britain. While one recorder credits Germany, another Italy, as being its native country, it is likewise chronicled that Gerrard received it from Poland in 1597.

The species from which the present improved varieties in cultivation originated is said to be indigenous to England, where it has been found a habitant of rocks and old walls. Whatever its native country is of minor importance, sufficient that we know that it has been cultivated in Europe from time immemorial, and that its appreciable qualities have not degenerated, but continue yearly to improve. In early times, when the Carnation had comparatively few rivals with attractions to commend them to share the sovereignty of the garden, she was the recognised queen of summer and autumn, her insignia for this exalted rank being the brilliancy and diversity of colour, stately habit of growth, handsome symmetrical form of flower, united to refreshing sweetness of perfume. But of late years the Carnation, along with other hardy plants, has in a measure been in the shady side of popular esteem, and we now join the unanimous voice which recalls her to a place of honour in every garden.

Classification.—There are several distinguishable features which separate the Carnation into groups, by which we have what are designated Bizarres, Flakes, Picotees, and Sells or Cloves. Bizarres exhibit in their white petals, irregular stripes, and spots of two different shades of colour. Flakes are distinguished by being composed of two colours—the ground colour, and flakes of rose, scarlet, or purple. Picotees are determined by having a margin or lacing around the petals. Sells or Cloves have only one colour, either white, crimson, scarlet, purple, or other intermediate shades. Each division furnishes endless varieties, which are subdivided into the following:—Scarlet flake, pink flake, yellow flake, &c. The same rule is applied to describe Bizarres and Picotees, but applies to the lacing of the latter. In addition to the foregoing, we have the much-valued Tree Carnation in grand array. These are almost exclusively cultivated in pots, and will be treated of separately.

Propagation.—This is effected by layers and pipings when the object is to multiply approved varieties, and by seed for procuring new sorts. *By Layers*: The time to propagate by this means is just when the early flowers have expanded; and the method of procedure is first to have sifted through a fine sieve a mixture composed of river sand two parts, loam one part, and leaf mould one part. With this form a little mound around each plant to be operated upon; slope the mound down until it joins the base of the plant, so that the layers conveniently bend and lie to it without disjoining them. When completed, proceed further by taking the shoots intended to form layers, and cutting away the lower leaves. Then insert the knife about half an inch below the third joint, and make an incision into the centre of the joint, directing the knife up the centre of the stem. Cut away the extreme end of the tongue thus formed by the insertion of the knife. The layer is next bent down to the ground and fixed in position by means of a hooked peg, being careful that the incision is left open when fixed. When all the layers on the same plant have been operated upon, finish by putting a covering of the compost over them, and water well with a pot furnished with a finely-perforated rose. Their subsequent demands are only a watering occasionally, should the weather prove dry.

The afternoon of a hot day is perhaps the best time to perform layering, when the plants are rendered less or more flaccid by the heat of the earlier part of the day, and therefore more pliable than would be the case in the morning when they are glutted with the sap accumulated overnight. By the end of September the layers ought to be sufficiently rooted to have

them severed from the mother plant. Detach them by cutting close to the part where they are layered, retaining as much of the soil as will adhere to the roots, and allot each a pot according to the size of its roots. The soil for this purpose should be two parts rich loam, one of sharp sand, and one of leaf mould. Plunge the pots in a cold frame in coal ashes, and supply water enough to saturate the soil in the pots. Keep the sashes entirely up to admit air, but shade gently for the succeeding ten days in strong sunshine.

The commencement of November is quite soon enough to afford the protection of glass, and this only in sharp frost. Continue to supply unlimited ventilation—unless in frost—day and night all through the winter, remembering also that every blink of sun is acceptable, causing a quiet flow of sap in circulation, by which the health of the plants is improved. Under this winter treatment there is little to be feared from damping-off, or mildew, or any other malady, if the roots have made a proper move before frost sets in.

Insects.—When Carnations are exposed to a closely-confined atmosphere, it invariably follows that they are attacked by green fly. The first appearance of these should be the signal to effectually destroy them by a smart application of tobacco smoke, or by syringing overhead for a few days together with a weak infusion of tobacco water. There are other safe expedients—namely, puffing with Pooley's tobacco powder, or even dry snuff. Wireworm at the roots is assuredly the most destructive enemy to which this plant is subject, therefore it should be the cultivator's careful look-out first to ascertain that none exist in the compost before using it. Sometimes it is a difficulty to get loam quite clear of wireworm, as whole districts are often infested; but where they must be contended with, an effectual cure may be obtained by spreading the soil into a body of a foot deep some weeks prior to using it. Into every few feet of surface insert a piece of Carrot or Turnip, and after a few days, so that the worms have been attracted to the feast, look over the traps, and treat those caught to an exceedingly "warm bath." Continue daily to give the creatures your attention until the entertainment thus provided them is wholly forsaken, when it may be concluded that the last has been killed.

General Culture out of Doors.—That the Carnation may grow luxuriantly it must have an aspect sheltered from cold winds, free exposure to sunlight, a rich and perfectly-drained bed, that has been previously enriched with well-rotted cow manure, and the soil trenched at least 15 inches deep. The bed should contain a good per-centage of rich fresh loam taken from old pasture, which has been rotted in a heap and frequently turned before being mixed with the bed. The ground should be trenched in the autumn, and allowed to lie rough until early the following March, when it ought to be forked and levelled down, and the plants put-in in rows, 1 foot apart in the rows, and 14 inches between rows. Should severe frost set in after planting, the plants must be protected by means of hoops extended across the bed, and a covering of mats securely put over them. When the flower-stems have advanced in growth a bit, have them all secured to neatly-dressed stakes, tying them at intervals as they require, to prevent the wind breaking them; and should the weather prove dry and hot, an occasional watering of weak liquid manure will aid in improving the quality of the flowers. Stir the surface now and then, and keep the ground free of weeds.

As the blossoms approach opening, it will be found that a number of the more double kinds show a tendency to rend their calyx by being too severely distended. To obviate this it is necessary to tie a thread of matting securely around the calyx, which will be quite hid when the flower expands, and the character of the flower preserved.

Propagation by Pipings.—The general fault and reason for failure by this mode is the season being too far advanced before the pipings are put in; and it will be found that propagating by this mode can be turned into a success if the pipings are put into gentle heat at the time when the plant shows a disposition to grow, instead of waiting until the usual time for layering. In preparing the pipings they ought to have the lower leaves cleanly cut away close to the stem, and the shoot cut across below the second or third joint; and without allowing them to flag in any degree, have them inserted into a rather firmly-prepared bed of sand and leaf mould, with a thin covering of sand over the surface. A gentle bottom heat is essential, and the bed previously watered, but the superfluous water drained off. The house or frame must be kept both close and shaded, and moderately moist until the pipings are

rooted, which will, in all probability, be in three weeks or a month.

By Seed.—Sow the seed in October in well-drained pans in, light porous soil, and place in greenhouse temperature over winter; put the seedlings into small pots when they have reached a size making them capable of being handled; and, if necessary, in the spring, and plant out at the latter end of April, and the most of them will flower before September.

Tree Carnations.—These are best multiplied early in the spring, when they root with speed, and with few failures. The plants should be potted without delay, into sizes of from 4 to 6 inches diameter, according to the extension of the ball of soil adhering to them when taken out of the cutting-bed. Allow them generous diet, but the prevailing material in the compost must be fresh fibry loam; second to loam in importance is a sufficiency of properly-reduced cow dung; drain extra, and pot firmly without ramming. Repot as soon as the roots net the exterior of the ball, repeating the same again and again, to whatever size of pot the roots require to contain them. Have no thought of limiting the size of pot to induce the plant to flower; flowers will come by-and-by, and the bigger the plant the greater the success both in size of blossoms and in numbers.

SELECTIONS FROM THE BEST COLLECTIONS.

Scarlet Bizarres.—Admiral Curzon (Easom), Coriolanus (May), Dreadnought (Daniels), Duke of Wellington (Bragg), Lord Derby (Heap), Oliver Goldsmith (Turner), Splendid (Martin), William Pitt (Puxley).

Crimson Bizarres.—Black Diamond (Haines), Eccentric Jack (Wood), a magnificent flower of large size, finely marked; Graceless Tom (Wood), Hope (Puxley), pretty; Lord Raglan (Bowers), fine; Phidias (Wood), Rifleman (Wood), in crimson bizarres one of the most beautifully marked; The Lamplighter, another splendid flower, by the same raiser as Rifleman (Wood).

Pink and Purple Bizarres.—John of Gaunt (May), Master-piece (Schofield), Purity (Wood), Shakespeare (Puxley).

Purple Flakes.—Dr. Foster (Foster), Earl Stamford (Elliott), Florence Nightingale (Sealey), Mayor of Nottingham (Taylor), True Blue (Taylor).

Scarlet Flakes.—Annihilator (Jackson), Christopher Sly (May), Illuminator (Puxley), first-rate; Marshal St. Arnaud (Puxley), Mr. Battersby (Gibbons), one of the best; William Cowper (Wood), a clear and beautifully-marked flower.

Rose Flakes.—James Merryweather (Wood), Lord Belper (Turner), Mr. Martin (Elkington), Nymph (Puxley), Rosabelle (Schofield), Rose of Castille (Headly), Samuel Moreton (Addis).

Cloves.—Bride (Hodges), pure white, splendid flower, robust grower; Ghost (Turner), a lovely white; Hindoo (Turner), deep crimson, extra; Pioneer (Turner), salmon and scarlet; Purple Prince, extra; Scotch Clove, dark, neat habit; Napoleon III., brilliant scarlet, &c.; Old Crimson, rich maroon-crimson.—A. KERR.—(The Gardener.)

THE KENTISH FRUIT CROP OF 1873.

In a district like that which surrounds Maidstone the importance of a good fruit season is greater, perhaps, than that of a good crop of Hops, for although the money value of the latter may be larger, the community benefit more by the former in the increased labour the ingathering involves, as well as the advantages which large towns and remote and less favoured districts obtain by fruit being plentiful. As the present season has, on the whole, furnished us so far with better crops than either of the last two, a brief allusion to the causes which seem to have led to this result may not be out of place, especially as the spring was certainly not favourable to the fruit crop in general.

With the exception of Plums and Pears most fruits seem to be plentiful. To some it may appear strange that a season that has proved favourable to the Apple should not also have been so to the Pear and Plum, but such has not been the case. These fruits bloom earlier than the Apple and the Plum in particular, but severe weather may have told on them before the Apple was far enough advanced to suffer; for I find we had a succession of frosty nights following the 22nd of April, with occasional showers of snow, hail, and rain, also ice one-third of an inch in thickness on the morning of the 26th of that month. This, followed by a bright sun on the same morning, proved fatal to the Pear and Plum blossom, likewise doing much damage to other crops. The wonder was that anything escaped. Certainly grass and other herbage suffered as well as the fruit crop, and at the end of April everything might be pronounced late. Matters did not mend much in May. True, there were no severe frosts like that on April 26th, nor yet so disastrous

as that of May 12th, 1872, which destroyed Gooseberries even fit to gather; but a succession of dull ungenial days with slight frosts in places culminated in a sharp frost on the 11th, which would have been more serious in its consequences had the morning afterwards not been dull. As it was, doubtless it did a certain amount of harm, and it is very possible the scarcity of Apples in certain places or on certain trees may be traced to this source; but ungenial weather continued throughout the whole of May and up to June 20th, when by degrees it became somewhat warmer. Up to that date, and even later, everything presented a backward appearance. Wheat did not fairly come into ear until several days beyond the average time, and only two days earlier than in 1860; while grass and other crops were almost stationary until the middle of June, when rapid growth set in amongst all kinds of hardy vegetation which the dryness of May had kept back, and a tolerably good though late hay crop was the result. Most of the small fruits benefited in a like manner by the change of temperature.

Strawberries looked well throughout, thus proving that if that fruit can be protected from frost while in bloom it does not require so much sun for its growth as other fruits; in fact, it would appear that the Strawberry is better suited to a cool moist climate than to a dry warm one, and possibly will exist farther north than other fruits. This season has been one of the best I have ever known for Strawberries. Gooseberries have also been plentiful and good, but unusually late, some being scarcely ripe in the first week of August, when the birds began to carry them away; the crop has likewise been good. Red Currants have also in most places been good, and the foliage has escaped the attacks of insects, which is a good augury for next year. In some places, however, failures are spoken of. In some cases Black Currants have been bad, the fruit being covered with a sort of brown rust; it was also small; but I believe that generally a full average crop may be reported. Raspberries have, I think, been better in some previous seasons, yet the crop cannot be complained of; only the quantity grown round here is small as compared with that of other fruits, although equaling that of Strawberries, but both these fruits reach the market in better condition when grown near to it, hence their paucity around Maidstone.

We now come to the larger fruits; and omitting Cherries, of which I can only speak from the observations made by others, and which are very conflicting, I need only say that if 1873 has not been a Cherry year it has not been without them, the late kinds being tolerably plentiful, and I believe that a fair average crop of Cobs and Filberts may be reported; not so heavy as in 1870, but on the whole good. As to this, however, I speak with some diffidence, as there is a difference of opinion about them; but there is only one opinion about the crop of Pears, and that is, it is all but a total failure, both early and late kinds suffering alike from the severity of the season, so that there are in reality very few Pears, although there was no lack of bloom, and that, too, of a promising kind. Plums are also a thin crop, or rather irregular, for in a few orchards we hear of fair and even good crops, and in others there are none at all. In our own case we had too many last year to expect much this season, but we find others who had a failure last season have had one this year as well. The same remark holds good with regard to Damsons, there being a few in some places, a good crop in a few others, while the bulk of the orchards will not be worth looking over. In fact, Damsons seem more scarce than early Plums, both being irregular.

In addition to the above remarks it is pleasing to have to record the general good appearance of the trees, so that if all go well there may be hopes for another year. Reference to this matter reminds me that last autumn, or rather the latter part of last summer, was a favourable one for ripening the bloom buds, which I cannot but think has helped the Apple and the other fruits which survived the cold ungenial spring we had, for a well-developed flower, perfect and vigorous in all its parts, is not so likely to succumb to a moderate frost as a weakly imperfect one would be.

One more observation may be here made with regard to the fruit crop, and that is the increased breadth of plantations of Apples, Plums, Damsons, and small fruits to be found everywhere. Certainly new plantations of these fruits are more plentiful than those of Pears and Filberts. No doubt the planters have duly weighed the chances of a fluctuating market operating in their favour or otherwise. Damsons, especially, have been very extensively planted of late years, and would become a drug were it not for the increased demand for fruit. How far the foreign producer can compete with the home

grower it is difficult to foresee. Certainly in all early fruits he has the advantage, and when there is a failure supplies will doubtless be sent in from abroad whenever the price allows a margin of profit.

Another circumstance affecting fruit culture at the present day is that immense quantities are now boiled down for jam, or undergo some preparation for use. The jam trade has within a few years attained a position never dreamed of years ago, when that article was considered one of the luxuries which only the wealthy could indulge in. Now it is sold at a price less than half that of butter, with which it successfully competes, and jam-preserving houses exist in most fruit-growing districts. Ten after ten of jam is prepared, and a neighbour of mine alone supplied several tons of Strawberries during the past season for this purpose. So great has this trade become, that small fruits, Plums, and Damsons, are not likely hereafter to go to waste for want of buyers.—J. ROBSON.

THE BEAUTIFUL AND USEFUL INSECTS OF OUR GARDENS.—No. 9.

Many insects of the Hymenopterous order are very puzzling to the naturalist who has not time or taste to dip deeply into entomological lore; not that it follows, indeed, that he would be much the gainer, for our nomenclature at present seems inclined to go, as the printers say, "all to pie;" but ignorance is generally confident, and the man who knows nothing about distinctive characters calls an insect a bee, a wasp, or a fly, without being troubled with doubts as to the correctness of the name. On the other hand, the naturalist knows that there are, as in the order cited, hosts of species looking exceedingly like each other, yet widely separated in structure and habit. We have many species of bees and wasps, and some of these are not at the first or second glance recognised, while other Hymenoptera, and even some Diptera, resemble these insects superficially. Gardeners are, I find, mostly quite awake to the fact that there are various species of wild bees of different sizes, but some of them have yet to learn that there are numerous wasps besides the wasp better known than loved, so frequent a visitant in ordinary years, and whose portrait (in print) has certainly been drawn with too deep colours, mischievous though it is. We have bees of diverse habit, popularly called, as the reader is aware, Upholsterer-bees, Carpenter-bees, Tunnel-makers, &c.; and thus among the wasp tribes are there many species which, so far from being hurtful or annoying to the cultivator of flowers or fruit, are decidedly of service to him.

It may be noted in passing, that the stinging Hymenoptera will very seldom use their weapons from wantonness; still, in pursuing investigations among those species of insects we are not sure about, it is needful to be a little cautious. "O! here's a curious fly," said a friend of ours, seizing a flower lastly with an insect resting thereon, said insect being no fly, but a bee, and taking its departure abruptly after leaving the handler a token of remembrance. I was reminded of the Irishman who, in some tropical country, caught, with an exclamation of delight, what he took for a humming-bird, in reality, however, a stinging insect, and his next remark was, "Bless me, how hot his little fat is!" The warmth of skin caused by being stung, however, is often accompanied by a swelling which is not agreeable; the application of an alkali, or a fomentation, so as to dilute the virus, being usually a speedy cure.

The Mason-wasps visit gardens, not solely for the purpose of obtaining honey, though they have a *penchant* for that product, especially as yielded by cultivated flowers. They also seek larvae, not for their own benefit, but to supply their young with food, since, from their structure and the position in which they are placed, it is impossible that they can forage for themselves. The illustrious Ray is believed to have been the first who observed, or, at least, the first who recorded, this peculiarity; and the worthy naturalist Romie, whose rather crude and disconnected observations on various departments of insect life have been so freely made use of by his successors in the field, enters at some length into a description of the economy of some Mason-wasps as noticed by him at Lee and in its neighbourhood. Several species of the genus *Ammodia* are common enough in the counties of Kent and Surrey, delighting in the sandy soil, and no doubt frequenting similar ground in other English counties. It is usual to speak of the "nests" made by these insects, though possibly the designation is not quite appropriate, as in each burrow or excavation only one egg is deposited: hence the insect labours on day

after day until her stock of eggs is exhausted or her strength fails, and she herself becomes, perhaps, the prey of some larger animal. I write in the feminine, as it is only the female wasp that works thus for the next year's brood, the male insect being distinguished for no good quality that I am aware of, and, like other idlers of the insect races, it enjoys but a short life. Both sexes are rather fly-like than wasp-like in their appearance, the abdomen being lanky and the legs long and slim.

The boring operation is performed chiefly by the jaws of the insect, the legs not having sufficient power to dig, though they aid in scratching out the material that has been loosened. In compact sandy soil it is often hard work, and yet such ground suits the wasp's purpose better than that where the sand is too loose and liable to fall in. Réaumur, in his observations upon this or an allied species, ascertained that the wasps soften the part of the bank on which they are engaged by letting drop upon it some fluid from the mouth, and thus render the stuff more workable. The chamber and passage having been completed, and the walls smoothed-off, the wasp deposits its egg, and then darts away to obtain the first instalment of food. This is a caterpillar, most usually of some moth or saw-fly, though Rennie states that in the chambers he opened he found larvæ without visible feet, possibly of some fly or beetle. The first deposit having been made, a second journey must be undertaken, and with admirable precaution the wasp blocks the door of the cell with pebbles or fragments; it may be to prevent the escape of the captive, and also to keep out intruders, such as the Cuckoo-fly, which might seek a rearing-place for its own progeny in an abode it had not constructed. Also Réaumur thinks she does this to prevent the heat of the sun hatching her egg too suddenly. At all events, the opening and closing of the hole is done again and again until the needful complement of larvæ is obtained—sometimes as many as a dozen, occasionally only half that number. These unfortunate individuals are immured much in the fashion of human wretches in the hold of a slave ship of other days, and thus "cabin'd, cribb'd, confin'd," they wait in darkness their turn to be eaten! With what has been called "crud instinct" the wasp almost always selects larvæ that are full grown, and therefore so far plumped-up as not to be likely to die of inanition. Of course, with regard to those particular larvæ, as they are full-fed, it might seem that the horticulturist was not much advantaged by their removal, and yet he is, in another aspect of it, since they would many of them, if not removed by the wasp, appear as moths the following spring. The young wasp-grub or larva emerging from the eggshell soon begins to reduce the dimensions of the conveniently-placed coil of larvæ, and being duly fattened (unless some sly parasite has eaten out its vitals, which does occur now and then), spins a cocoon, and by-and-by comes out as a Sand-wasp in its turn.

An amusing account has been published from the pen of Mr. W. Hewitt concerning the doings of the Hairy Sand-wasp (*Ammophila viatica*), a species that stores up spiders and not caterpillars. Therefore it can hardly be reckoned as a "friend" to the gardener, inasmuch as spiders, with very slight exception, are not among his foes—indeed, rather helpful to him. In liveliness this wasp exceeds its relative, for we are told that "these insects seem all velocity and fire. The spiders lie under the leaves of plants and in dens under the dry little clods. Into all these places the Sand-wasp pops his head. He bustles along here and there, flitting his wings and his whole body. Ever and anon he crouches close among the little clods, as a tiger would crouch for his prey. He seems to be listening or smelling down into the earth, as if to discover his prey by every sense which he possesses. When he finds the spider he dispatches him in a moment, and seizing him by the chest, commences dragging him off backwards." This narrative has a tinge of the imaginative, yet it may be accepted as true in the main. *Tripoxylon figulus*, a smaller wasp, of dark hue, and clad in silky down, is also a spider-hunter, and this insect has been seen to seize with singular dexterity a spider that was resting upon a web, and bear it off without entangling its own wings.

Carpenter-wasps there are also of the genus *Tripoxylon*, which form their nests in the stems of rosaceous plants (see *figs. 1, 2, 3, and 4*); they may be detected on the Bramble and wild or cultivated Rose. *Tripoxylon (Odynerus) alter-*

natum is almost sure to manifest itself by the round hole left at the end of the stem or branch. In this instance we have several cells, not a solitary one, and for each small grub there is due provision made by the mother insect. As flies are

Pupa of *Tripoxylon*.

selected, especially certain of those that are troublesome in the orchard, we are gainers by the labours of this wasp. The nest, or series of cells, is so planned that the new brood emerges in the reverse order to that in which the eggs were laid, so that the later-hatched are not interfered with by those that are mere forward. Other Carpenter-wasps perforate dry posts, and, under an arrangement very similar, also kill and lay-up flies.

The Hornet (*Vespa Crabro*) is regarded with terror which is almost ludicrous, and the statement is frequently repeated that "three hornets can kill a horse." If such a thing could be true, it is certain that the hornet is not accustomed to attack the equine race, nor man, unless provoked thereto; and, what is rather comical, people sometimes rush off in a fright from a supposed hornet, when, in reality, the object they see is most harmless, belonging to the *Sphix* family, of which some members have a close resemblance to bees and hornets. Nearly related to the wasp, it is yet one of the most determined foes of that insect, though it will not disdain to touch ripe fruit. The lesser species, agile, and provided with a sting as it is, has no chance of making a successful resistance, and is crunched up by the hornet much as a lion would seize a kid—at least, not precisely so, since the hornet only sucks the juices of wasps, and casts the carcasses away. The nest of the hornet (*fig. 5*), is rarely or never placed beneath the ground,

Fig. 5.—Hanging Hornet's nest.

the insect preferring to resort to rotten trees, which supply material for the structure. This is generally coarse, and swung from some secure point of suspension; Réaumur exhibits a figure of one looking like a pear in shape, with a raised dome. That our information about the habits of the hornet is but scanty is quite explainable by the character of the insect, which does not invite intimacy. The old ladies of

the community live through the winter, and some four or five in concert start the colony of the next season. An ordinary hornet's nest is seldom found to contain more than about 150 individuals, size making up for numbers.—T. R. S. C.

FLOWERS FOR OUR BORDERS.—No. 16.

LARDIZABALA BITERNATA.—BITERNATE-LEAVED LARDIZABALA.

Of deciduous climbers, whether hardy or half-hardy, there is, happily, no deficiency in our gardens; but the number of evergreen climbing plants hitherto available for general cultivation is so limited, that when we have named the common Ivy we have exhausted the list. To this valuable climber, which, although possessing few claims to beauty, is deservedly esteemed for its utility in covering walls and concealing other objects offensive to the eye of taste, the *Lardizabala biternata* will prove a formidable rival; for it appears to be equally hardy, produces its beautiful dark green glossy foliage in great abundance, and has, moreover, the additional recommendation of bearing flowers of a singularly interesting character, which in the case of the fertile blossoms, are succeeded by an edible fruit.

It is a native of Chili, growing as far south as Concepcion, whence it was sent by George Thomas Davey, Esq., of Valparaiso, to Messrs. Veitch, of Exeter.

The specific term, *biternata*, does not appear to be very happily chosen; for, although some of the leaves are biternate, they are more generally simply ternate, especially in the flowering branches, and occasionally they are tri-ternate. The leaflets are often quite entire at the edge, but sometimes spinosely-toothed, of a dark green colour above, but paler and veined on the under surface.

The *Lardizabala biternata* is an illustration of the dioecious class of plants; it is, in fact, both dioecious and polygamous; for, although the flowers of the plant represented in our figure produce stamens only, those of the fertile plant, which has not, we believe, been yet introduced to this country, yield both stamens and pistils; it differs also from the sterile plant in its one-flowered peduncles. These solitary flowers are succeeded by a many-seeded berry, which is sold in the markets of Peru and Chili. The pulp is said to be sweet and grateful to the taste. Its stems yield a very strong fibre, which is made into cordage.

The blossoms of the male plant are borne in drooping racemes, hanging from the axil of a leaf, the peduncle or flower-stalk bearing at its base two large heart-shaped bracts; and it is remarkable that these occur at the axil of the leaf, even where there is no flower-stalk. The calyx is formed of six fleshy sepals, arranged in two series, three of the segments being external to the others when in the bud. The calyx is the most highly-coloured portion of the flower, the petals being comparatively inconspicuous, and of a thin membranaceous mealy texture. The six stamens are united by their filaments into a column (monadelphous), and bear six oblong, incurved, pointed, two-celled anthers, which open at the back.

With regard to the propagation of the plant, it may be effected both by cuttings and layers, in any ordinary soil. It will flourish in any situation not too much exposed to the sun,

but appears to prefer shady places; and as it grows rapidly, when well established its merits as a substitute for the Ivy will, doubtless, soon be universally recognised.

In Peru, where it occurs as well as in Chili, it is called by the Indians *Aguilboguil* and *Guilbogui*; in Chili, its native designation is *Coquil-vochi*. Two other species are described by botanists, *L. tri-ternata* and *L. tri-foliata*, which appear to differ from the *L. biternata* in not producing an edible fruit.

The plants of the order *Lardizabalaceae*, although few in number, are all of interest; they were formerly included with the *Menispermaceae* or *Cocculus* tribe, to which the narcotic berry known as *Cocculus indicus* belongs, but are now classed apart, their many-seeded berries distinguishing them from the plants just referred to.

The order *Lardizabalaceae* commemorates the services to Natural History of Michael Lardizala, of Uribe.—(*Thompson's English Flower Garden, Revised by the Author*).

FLOWER SHOW AT ALTON TOWERS.

Few places in the county of Stafford have done so much to cultivate and encourage a practical love of plants and flowers as the Alton Floral and Horticultural Society, and fewer still whose labours have been rewarded by so great a merd of genuine success. Its autumn exhibition on the 28th ult. was characterised by all the elements requisite for a consummation of its cherished desires—an increase in the number of exhibits, an improvement in the quality thereof, and a larger assemblage of those desirous of seeing what scientific knowledge and industrious patience could achieve than could have been expected while Jupiter Pluvius dispenses his meteorological favours so freely.

Especially prominent in the all-England class was the fruit, and, as is always the case at this Exhibition, it stood far above everything else for attractiveness. There was a wealth of Black Hamburgh and Muscat Grapes, the chief prizes for which were won by Mr. Silcock, gardener to Sir C. Shakerley, Somerford Park, Cheshire; while the Peaches of Mr. J. Turner, gardener to Basil Fitzherbert, Esq.; the Nectarines of Mr. Bannerman, gardener to

Lardizabala biternata.

Lord Bagot; and the Pine Apples of Mr. Miles, gardener to Lord Carrington, sorely tempted the visitors. Florally the Dahlias took the palm, those shown by Mr. Painter, of Smallwood, Cheshire, and Mr. J. Sheldon, Derby, well deserving the first prizes awarded for twenty-four and twelve respectively; though relatively the Roses were scarcely inferior, the thirty-six of Messrs. Paul & Son, Cheshunt, the twenty-four of Messrs. Perkins & Sons, Coventry, and the twelve of Mr. Samuel Eyre, Leek, being much superior to the collections shown by their opponents. The plants were most effectively arranged on a pyramidal circular stage in the centre of the show-tent, the Roses being placed round the base; the collection of ten exhibited by Mr. T. Rabone, gardener to the Earl of Shrewsbury, which took the premier prize, included magnificent specimens of *Bougainvillea glabra*, *Saccolabium guttatum*, *Caladium bicolor*, *Corypha australis*, and *Peristeria elata*, the first-named Orchid being especially well-grown. For the Fuchsias, Mr. Chitty, Uttoxeter, took the first prize, as did Mr. Walker, gardener to Capt. Dawson, Barrow Hill, for *Geraniums*, *Ferns*, and *Petunias*.

The Judges were Mr. George R. Tillyard, gardener to the Earl of Yarborough, Brookley Park, Lincolnshire; Mr. Temple,

gardener to the Earl of Aylesford, Paekington Hall; Mr. Brown, gardener to Earl Howe, Gopsall Hall; and Mr. Wilson, nurseryman, Warwick, their awards giving general satisfaction. About four thousand visitors were present, from Birmingham, Northampton, Derby, Leicester, Sheffield, Barton, and the Staffordshire Potteries.

MESSRS. BACKHOUSE & SON'S, YORK.—No. 2.

In resuming my notice of my visit I feel more than ever, on reading what I have already written, how very inadequately I have described my impressions, and how little it can give people an idea of the beauties of the Alpine Garden; still I may do something in noting some of the beauties that I saw, as there are, I believe, many who value these flowers and would be glad to introduce them into their gardens. It is not essential that they should be in an alpine garden, as many of them are suitable for herbaceous borders. Fragrance is not wanting in some of these flowers; nor are curious forms wanting, for suitable places have been made for hardy Orchids. Here, for instance, is the grand *Cypripedium spectabile*, the great American Lady's-slipper, with stems 2 feet high and showy white flowers, and our native one *C. Calceolus*, and *C. pubescens*, another American species. *Orchis latifolia* Traunsteineri with brilliant purple flowers was also to be seen, and *Opuntia Rafinesquiana* was flourishing. *Senecio argenteus* is well known for its pretty silvery foliage; but a fine orange-flowered one, *abrotanifolius*, was also very conspicuous. Of course the graceful forms of Ferns were not wanting, and many which we are in the habit of considering as only fit for the greenhouse were here flourishing in the open air. I shall hope to give a list of the best Alpines I know.

But deeply interesting as the Alpine Garden is with its gems and beauties of all descriptions, and wonderful as is the collection of alpine plants in pots, perhaps the most unique spot about the place is the Fern Valley, in which are cultivated about seventy or eighty kinds of *Hymenophyllum*, *Trichomanes*, and other Filix Ferns. I do not know the exact measurement of this charming fernery, but I believe that 120 tons of rough sandstone were used in its construction. The entrance to it is through the private grounds, for reasons which will be clear to everybody who knows the nature of this lovely tribe, and who can appreciate the tender care with which they are nurtured. It is about 9 or 10 feet deep, and narrow. The roof is of thick glass and iron; and the fernery is in two divisions, one for those belonging to tropical climates, and the other for hardier species. But the division is not absolute. There is simply a stone arch without any door to it. The far end, which is reserved for the tropical species, is heated by a warm tank. The heated air rises from this and reaches the stone arch; here it is met by a cool current from the other portion of the house, which passes underneath the heated current, and the result is that a condensation of vapour is produced, which results in a continued dripping and a most beautiful deposition of the finest dew, which no sprinkling or syringing with a rose however fine could effect, and the plants live in the very atmosphere most suited to them. Here were flourishing in the greatest luxuriance from ninety to a hundred species of *Trichomanes*, *Hymenophyllum*, &c. Here, for instance, one sees a lovely mass of the beautiful *H. tumbridgensis*, and there another of *Trichomanes radicans*, one of the lovely native species, which thrive here as well as in their native habitats. Amongst the more beautiful and curious of the *Hymenophyllums* were *scabrum*, with fronds 10 or 12 inches long and very finely divided; *puleherrimum*, well deserving its name; *demissum*, with bipinnate fronds, very finely divided; *caudiculatum*, with broad fronds, with the ends lengthened-out into fish-like points, like some of the native Ferns; *dilatatum*, with broad bright green fronds; *cruciatum*, most beautiful—so beautifully transparent are the fronds of this species, that I could see to read the smallest newspaper print through it!—*fusiforme*, a native of Chili, which Mr. Backhouse thinks one of the finest yet advertised. Then amongst the *Trichomanes* were, besides *radicans*, the very curious reniforme with its large kidney-shaped fronds of a bright green colour, the sori standing all round the edge of the frond, giving it a remarkable and handsome appearance; *Insepnatium*, a dark green climbing species with sessile fronds; and probably nowhere can the species be seen in such perfection as here, for, while rejoicing in moisture, it does not like syringing; *alatum*, very handsome, the fronds growing from 9 to 10 inches high; *anceps*, very large and fine; *membranaceum*, a dwarf climbing species from the West Indies, and very handsome.

But I must stop, for what is the use of adding a number of names, which will only be travestising some first-rate catalogue? All I can say is that I had no conception of the extreme beauty of these plants when grown in the state of perfection here seen, and that a more pleasing sight it would be impossible for a Fern-lover to have his or her eyes gratified with: and that, as far as I myself am concerned, it is in very deed *diverta notanda*. And what shall I say of the *genius loci*? Those who know aught of James Backhouse know him to be a man of science as well as a thoroughly good gardener. He, with his late father, were amongst the favoured few who had the opportunity of seeing the grand solar eclipse of 1851 from the top of one of the highest points of the Fille Fjeld in Norway; and in a short paper he has recorded his feelings on the occasion, while in his dining-room hangs a strange weird-looking picture, in which he has placed on canvas his record of a sight which so few can witness. Need I say that he loves his plants? What stories I might tell of his clever tracking of rare native plants, and of the enjoyment of seeing his perseverance crowned with success! But he has other and higher qualities than these, and pleasant was the interview we had on greater matters. Gentle and loving as he is, he is well fitted to preside over scenes such as I have faintly attempted to portray, where some of the loveliest plants, minute though many of them be, experience his tender care—plants which show that not merely the grandest but the smallest of Nature's productions have been perfected by the same Almighty Hand. Meetings such as these are helpful to all who want rightly to fight the battle of life, and who would desire to cherish friendship on its highest and worthiest ground. And so farewell, good friend! Long may you preside over spots so congenial to you, and may your efforts be crowned now and ever with success.—D., *Deal*.

PRESERVING GRASSES, FERNS, AND FLOWERS.

GRASSES should be gathered early in July, if we desire them to retain their bright hues without the aid of art. Gathered then, tied up in large bunches, and hung away in a dark closet, they come forth at our bidding, fresh and green as when plucked. Now, by brook-sides or in shady places, we can find graceful Grasses, which will prove additions to our winter bouquets, but they will lose their colouring, and require a dip into "Judson's green dye." Dye them again, and they will last for years. Wild Oats, Feather Grass, and all their various species are very ornamental in winter, and mingled with the Everlasting Flowers—*Aeroclinium*, *Xeranthemum*, and the white, yellow, and crimson *Helichrysms*—they vie with their more perishable sisters, whose glories are on the wane. We have just arranged two small vases for the coming winter. The brilliant pink and white *Aerocliniums* add much to their beauty. The white *Helichrysms* can be dyed a brilliant purple or scarlet with Judson's dyes, and exquisite bouquets can easily be manufactured. These "everlasting" flowers should be gathered as soon as the outer leaves open. Tie them up in bundles as you pick them, and hang them up, flowers downwards, to dry. Treated in this way, the stems are straight and more easily used. They can be hung to dry in one's chamber, not requiring a darkened place. Most of these flowers are allowed to remain too long upon the bushes, and their beauty is spoiled. As they become dusty under the frequent sweepings of carpets, we dip them in cold water; their petals close entirely. We dip the Grasses also, to cleanse them, else they will acquire a dingy hue.

Many persons like crystallised Grasses. These are easily made by dissolving 1 lb. of alum in one quart of boiling water, suspending the Grasses just over the steam—not to touch the water—and as it cools, the crystals gather. Grasses need not be dried before they are crystallised. A few of them mingled with the green Grasses and brilliant-hued flowers light up well.

Ferns are much sought after for floral decorations. Their feathery plumes, pinnated leaves, and graceful forms are very beautiful. They differ from the Grasses, for those gathered late in the autumn retain their colours better than the fresh Ferns of June. The sap has hardened in their leaves. We have gathered them late in November, when they were surrounded by snow, and they have kept green all winter. The running Fern is a lovely decoration for walls and pictures. Its flowers add much to its grace and beauty, but it fades quickly, and by Christmas but a faint green remains. Dip them in Judson's dye (following the directions given on the bottle for dyeing ribbons), and you will keep their lovely colour. After they have been thoroughly pressed in heavy books, then

dye them, spread on paper to dry in the shade, and then press again. Thus treated, they will last for years. Maidenhair, the most graceful of our Ferns, soon loses its colour; but dyed, it is an addition to every collection of Grasses or Ferns.

Parsley Fern is very beautiful; its soft, feathery leaves are always sought after. These, if gathered late in the autumn, will retain their colour much better. The Male Fern, with its stiff stems, if well pressed, looks beautiful. We mingle it with the many-coloured leaves of autumn, or we pin it to the wall paper, around pictures, or over lace or muslin curtains, and its effects are charming.

The branches of the Sumach, gathered soon after the frost has appeared, or even before, press perfectly, and keep their colours finely. If varnished with map varnish they never fade. Branches of this tree interspersed with the Ferns are very ornamental. We have made exceedingly pretty crosses from its leaves, sewing each one separately over the other on a pasteboard cross. Anchors and stars can also be made of its lance-shaped leaves. Thus suspended over engravings or curtains, they are very ornamental, and are easily dusted—an essential in the eyes of a good housewife.

Bunches of dyed Mosses are to be purchased of all seedsmen in the cities; we dwellers in villages cannot avail ourselves of them if we would; but we can make them even prettier than those exposed for sale. Gather the Mosses, pick out all the *débris*, cleanse from dirt, and dry in the sun; then dip into Judson's dye, spread on papers to dry by fire or sunlight. We gathered last year a very finely-fibred Moss, dyed it a lovely green, and saved some of the original colour to mingle its brown hues with it. Then we took the "hoops" from an old skirt, tied them together, and on the circle tied wreaths, which city friends said "surpassed those displayed at the shops."—(*Farmers*.)

REPOTTING ORCHARD-HOUSE TREES.

I OBSERVE that Mr. Douglas, who is a most successful cultivator, says (page 180) that he repots as soon as the fruit is off. I wish he would state how far he disturbs the roots in repotting. Where a larger shift is required, the earlier a plant is shifted the better; but most of your readers will understand repotting to mean the operation as described in Rivers's book, which, if carried out to the extent recommended by him, would probably injure the plant permanently, if not kill it. Such mutilation of roots and removal of soil seem safe only when the plants are preparing for rest. Of course, much may be done by syringing and shading.—G. S.

PYRAMID AND BUSH FRUIT TREES.

THE Apple, Pear, Plum, and Cherry alike, in these forms in the past two seasons as well as the present year, have not come up to the expectations which I, and no doubt others, had formed in consequence of former years' experience. Lately it cannot be said that they have been prolific in anything but wood. Those trees which I have seen have made more wood in the last three seasons than I have before noticed in double the time. Even with summer pruning or pinching it has been hard work to keep the strong growths in check. No sooner are the shoots stopped than they start again with redoubled vigour. Reports which we have from various parts tell no better tale. Nature, as it seems, in the matter of fruit trees is given up to growth, and when we look at this state of things how can we expect it to be otherwise? Let us go back a little. Were not 1868, 1869, and 1870, hot dry seasons, the climax being reached in 1870, when the crop of fruit was remarkable, especially in the case of trees grown in the forms now under notice? The whole tendency of those seasons was to induce fruitfulness; and did we not allow the trees to bear so fully and so well in 1870, that the effects are not yet effaced from them in 1873? I particularly noticed in 1870 that the trees had little beyond fruit-bearing shoots or spurs, and had so few spurs to develop into fruit-buds another year as to give but faint hopes of continued fruitfulness. The spurs, from the heat and dryness of former seasons, had become fruit-buds, and the result was their extinction on blossoming. A tree which bears a heavy crop one year gives but a small one or none at all the next. It is considered due to the heavy crop, but I am inclined to think it is rather the consequence of the majority of the spurs in the previous year forming fruit-buds. Were we to thin the fruit we should have it finer, but after we have allowed the blossom to expand, and the fruit to set, what

good is the thinning as regards next year's fruiting? It may at first thought appear to be of but small utility. The tree has no spurs, or but few, to mature as fruit-buds; but the fact is that in every spur from which we remove the fruit we set free the means of forming spurs which, if they do not turn into fruit-buds the season in which they are called into existence, they will not if fruit be allowed to be borne thereon, and these in the next or some future season will produce blossom and fruit. By allowing a tree to bear as much as it will we cut off its means of forming spurs not only for the next but also future years' bearing, but by judicious and continued thinning of the fruit, never allowing the tree to overbear itself, we provide for a number of spurs being formed in each season, and it is on those we have to depend for the fruitfulness of the tree from year to year.

The past two springs have not been favourable to the blossoming and setting of fruit trees, but though this in itself is sufficient to account for the indifferent out-door fruit crops, it is, nevertheless, not so easy to explain that whilst our bush and pyramid trees are unfruitful, the standard trees are bearing good crops. This applies, however, to standards of some age. How is it that the more aged of the standard trees are bearing, whilst those that are young are on a par with the pyramid and bushes, not having borne fruit in the two last seasons? I conclude, therefore, that these years have been exceptional; they have been seasons conducive to growth, and when such occur our prospect of fruit is not great, for no matter how often and well we may pinch or stop, the trees seem bent on growth, and summer pruning will not check it, and induce the formation of fruit-buds; or if they do form, they are not well developed, so that the blossoms do not set. It is known that with strong wood, though the trees may produce blossoms, these do not set, or drop off at an early stage. All kinds of reasons are given for the trees not bearing, but I find that when Nature smiles we have fruit abundantly, when she frowns man's art is useless to stay her ways.

It has been contended that working on dwarf stocks also dwarfs the graft or scion, and conduces to early fruitfulness. In some instances we have abundant evidence that trees on dwarf stocks are prolific of fruit at an early stage or age; but whether we use a free or a dwarfing stock, the effect is to give to the trees a prolificacy, which in some kinds soon ceases, whilst in others it is permanent. Every tree placed on a foreign stock is temporarily more prolific, and because we have fruit at an early age we are apt to attribute the result to the working on a dwarfing stock. This, however, coupled with the frequent transplanting to which young fruit trees are subjected, though it contributes to early fruiting, is not permanent in some, and, I may safely say, a majority of kinds. They soon overcome the influence of the stock and the early transplantings, and are given up to growth or to fruitfulness just as Nature dictates.

I have made these observations apart from root-pruning or biennial or triennial lifting. I believe the fertility of the trees to be dependent more on that than on any influence of the stock on the graft. Root-pruning or lifting tends to check growth and to age the tree, and so does grafting or budding, but the effect in either case is, as I have observed, but temporary; yet as we cannot always be grafting, if we mean our trees to continue bearing we must have recourse to root-pruning and lifting if we wish to keep them fruitful and of a reasonable size. After all, then, there is not much difference between trees on a free and those on a dwarf stock, the ultimate result is in what we make the trees by the culture pursued. Root-prune or lift a standard tree every alternate year, and we find it fruits as well and as regularly as the same kinds on a dwarfing stock, as a bush or pyramid. Take Lord Suffield Apple as an example. It bears early and regularly whether it is on the dwarf stock in the pyramid or bush form, or on the free stock as a standard. On either it is prolific—a regular bearer. It needs no lifting nor root-pruning on either stock or in either form. But this is a solitary instance. Cox's Pomona, Hawthornden, and others could be named in proof of the early and constant fruiting not being due to the influence of the stock. It is the nature of the variety. Another example, but to the contrary, may be found in the Hlenheim Orange or Pippin. What is the good of the dwarf stock to it? The tree will not bear on it unless the roots are hacked every second or third autumn, but grow it does, and it refuses to fruit until it has a head quite as large as the standard on the free stock. Summer-pruning does not mend matters. It is the nature of the subject to attain some goodly proportions ere

it produces fruit of note. Root-pruning will afford us fruit on either stock whilst the tree is young. Why, then, attribute an influence to the stock which it does not possess?—G. ABBEY.

STONES IN POTS.—I agree with the writer (page 175) that stones are beneficial, and impede the soddening to which fine soil not filled with roots is subject. But I think pieces of broken brick are better still, because their porous nature gives more hold to the roots, and they also act as a reservoir of moisture.—G. S.

NOTES AND GLEANINGS.

In addition to the exhibitors mentioned last week, Messrs. Dick Radclyffe, & Co., of High Holborn, London, obtained a medal of merit at the VIENNA UNIVERSAL EXHIBITION for seeds and horticultural tools.

— A HANDSOME specimen of the CAMBERWELL BEAUTY (*Vanessa Antiopa*), was caught in the grounds of J. S. Oxley, Esq., on August 28th, by Mr. G. Hodder, gardener, Spring Well, Clapham Common.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE weather still continues favourable to the growth of the autumn crops, the whole of which, when necessary, should now be kept well earthed-up. Young weeds will now be making their appearance in abundance where seeds have been allowed to ripen and fall during the summer. The whole of the garden, when it is possible to do so, should be gone over and scuffled with a Dutch hoe on a fine warm day, so that the young seedlings may die. Prepare ground for the main spring crop of *Cabbage*; it should be highly enriched with manure, as the plants will remain in the ground sixteen or eighteen months. A quarter on which Onions have been grown is very suitable for this purpose. Prick-out the young *Cauliflower* plants as soon as they are sufficiently large to fix in the ground. Some may be pricked into a sheltered border and some into frames. The *Cucumber* plants in the forcing house must now be carefully attended to; every means must be used to keep them free from insects and in a healthy vigorous state. When the plants get firmly rooted give them a little manure water every alternate time with clear water. Prick some of the *Cabbage* varieties of *Lettuce* into a frame to come-in for winter use; also continue to plant-out strong plants of the *Brown Cos* for autumn use. Pull-up those *Onions* that have done growing, and house them in a dry state. They should be sorted before being laid away in the root-cellar, and the thick-necked ones used first. Thin the plants of *Spinach* to about 9 inches apart. If obliged to step in among them, loosen-up the soil after the thinning is completed. Take the opportunity of thinning the *Turnips* as soon as they have made a rough leaf or two. Should slugs attack them, which is not unfrequently the case at this season, sprinkle two or three times a-week, about nine in the morning, with soot or lime.

FRUIT GARDEN.

Peaches and Nectarines should be looked over every day and the fruit gathered before it is dead ripe; if placed on shelves in the fruit-room with soft tissue or silk paper underneath them, the flavour will be better than if allowed to hang too long on the trees. After gathering what fruit is ripe, the trees may be sprinkled with clean water in the afternoon of a fine day, but unless in extreme cases it would not be advisable to water now any more at the roots, as the sooner the growing tendency can be stopped and the maturing process completed the better. If the heavy autumn rains, which we may expect before long, could be thrown off the borders by tiles puddled with clay, or by boarding, &c., we should suffer less from severe winters than if the borders, allowed to get dry in July and August, have been deluged with rain at the end of September and in October. Unless the borders are particularly well drained, a second growth will take place, the vessels of the wood will be charged with a superabundance of watery fluid, and if a severe winter ensues, black and brown-spotted, cankered, gummy, and dead wood in the spring will be the consequence. Some Apricot trees are having their leaves slightly dotted with mildew, but instead of watering at the roots the leaves might be syringed with sulphur and water.

FLOWER GARDEN.

Carnation-layers which are rooted may now be potted. Pinks should also be bedded-out when well rooted. Keep *Chrysanthemums* neatly tied-up, and at all times prevent their rooting through the bottom of the pot. China Roses may now be propagated by cuttings with facility. Gather ripe seeds, and pull-up those plants in the borders which have done flowering, and of which seed is not required. The lawn, which has lately been but little trouble, will now require to be frequently mown. Turf

may now be laid down. Keep *Dahlia*s securely tied to strong stakes.

GREENHOUSE AND CONSERVATORY.

From this time to the end of October there will be a good deal of potting for furnishing gaities for the conservatory. *Tropeolum tricolorum* and others should now be potted to come in in April. *Lilium longilorum* and *eximium*, the latter only a slight variety of the other, to flower early in June should now be potted; also the beautiful varieties of *Lilium lancifolium*, to flower next July, should now be in pots, but October is time enough to pot all these if they are not wanted before their usual time. By way of experiment all these and others should be kept back as long as possible, in order to have fine flowers. The spring-flowering *Cyclamens* are very desirable plants. They should now be potted, and in the summer be gradually allowed to get dry, in order to be stored away for the winter. Plants of this genus should always be marked with their names, as they are apt to be confused; and as some of them are at rest while the others are in full growth, it may happen that they might receive wrong treatment. The earliest crop of *Hyacinthus*, *Narcissus*, *Tulips*, &c., should now be making root freely in the new pots, and very soon the whole host of *Iridaceæ* must be looked over and arranged for potting. There are few in this order that will do for forcing, but by potting some of them early in September, others late in the autumn, their flowering season may be prolonged, and so with *Oxalis versicolor* and *cernua*; kept near the glass in a stove or forcing pit, they would be in bloom by the middle of March. The *Oxalis cernua* has flowers of as fine a yellow as those of the *Allamanda cathartica*. Violets must soon be potted and placed in frames for forcing.

STOVE.

Many useful plants in that section which flowers in winter and early spring in the stove may be brought sooner into flower by checking their growth about this time. This is done by diminishing the usual quantity of water and by keeping the house drier; others of the same sort may be encouraged to grow as late as they will, in order to succeed these. Every pot plant should be looked over, one by one, at any time when the weather is bad during this or the next month. It is not enough, however, that the outside of the pots and the surface of the soil are cleaned over; the soil must also be turned out of the pots, worms looked after, the drainage relieved from the sediments which the summer waterings have washed down among the crocks; and if the pot is at all covered with green slime, do not use it, but take a dry clean pot of the same size, then add to the surface a little fresh soil of the same nature as that already in the pot.

PITS AND FRAMES.

Continue to propagate plants as fast as possible, and if those that are already rooted can be hardened-off, so as to have a fortnight or three weeks' exposure before they are housed for the winter, it will be all the better for them. Stocks sown at the beginning of August will now be of a fine size for potting. Fill the pots with good open compost, not too rich, and put two plants in a large 60, or three into a large 48-sized pot. They should afterwards be placed in a frame, and shaded until they are established. Auriculas and some of the more delicate Alpine plants should be placed in the frame, so that they may be protected from wet, which is far more injurious to them than cold. Rooted slips of *Verbenas* may now be taken off the plants in the open ground and potted into small pots; this will save the trouble of striking.—W. KEANE.

DOINGS OF THE LAST WEEK.

In last week's Doings it was stated that the weather was favourable to the spread of the Potato disease, and it has now appeared on the tubers on the farm at Loxford. They dig about an acre or more every day, and sort and weigh the crop, so that there is ample opportunity of knowing exactly how many tons are grown on each acre. Within the last two or three days two tons of diseased tubers have been dug from an acre.

FRUIT AND KITCHEN GARDEN.

There are some exceedingly fine *Coe's Golden Drop Plums* approaching to ripeness on an east wall, but as fast as the fruit gets to a certain stage it is attacked by *wasps and flies*. Several nests of the former were found in the immediate neighbourhood, and no time was lost in having them destroyed. The bluebottle flies are also very numerous. We find the best way to preserve the fruit is to cover the trees entirely with close netting, nailing the material closely along the top of the wall, and likewise making it secure at the bottom. Some oblique cordon Pear trees on a low wall are bearing an excellent crop of very fine fruit; the young wood had been cut or pinched-back twice during the season, and having again grown out, it was cut-back for the last time this year. This constant stopping of the young wood will cause the production of fruitful buds, and is on some soils preferable to root-pruning.

On the 5th inst. we made a sowing of *Onions*, *Lettuce*, and *Cauliflower*. As regards the Onions, in many gardens they are

so much attacked by the maggot that it is not possible to obtain a crop of sound bulbs. Where this is the case, sow in the first week of September. The varieties we prefer are Deptford, White Spanish, and James' Keeping. As regards Lettuce, we confine ourselves principally to one variety, Hicks's Hardy White; it has not failed to stand well over the winter with us during the last three or four years. It is a valuable Cos Lettuce, resembling in many respects the Paris White, but harder and of larger growth. We have not yet determined which are the best sorts of Cauliflower for our light soil. We have sown Early London, Walcheren, Lenormand's and Erfurt Dwarf Mammoth. Excellent heads are obtained from this sowing about the end of May and up to the middle of June. Later than June it is waste of ground to plant Cauliflowers in our garden—that is, it is useless to try to obtain heads after June. The present sowing will be planted in hand-lights in October, on ground trenched 2 feet deep. We have harvested the Onion crop; that from the autumn sowing was taken-up about the second week of August. We pull the bulbs up and lay them on the ground to ripen for a few days; they are then tied-up in large handfuls, and in wet weather the best are tied to ropes and hung-up in a dark close shed, where they keep well. Where there is a loft to spread them out it is a good plan to do so, and labour is saved.

We are gathering nice dishes of Peas from Alpha, though it is badly mildewed now. We tried Blue Peter in comparison with Little Gem, and thought the first-named superior in every respect to the last. Blue Peter is the best dwarf Pea, and can be confidently recommended. It so highly pleased my employer that he desired me to save all of it we had sown for seed, as he wished to grow it in the fields.

FRUIT AND FORCING HOUSES.

Until this week we have not had any fires in the *Cucumber house*, but the temperature has fallen to 50, and it is no longer safe to be without. We fancy that a low night temperature predisposes the plants to disease—at any rate, we cannot obtain well-shaped fruit unless a minimum of 60 be maintained in the house. Thrips is very troublesome to us, but we get rid of it on its first appearance by fumigating with tobacco; several smokings are necessary to destroy this pest. We recommend Telegraph as the best and most useful winter Cucumber which is yet in the trade.

CONSERVATORY AND PLANT STOVE.

We have been charmed with the *Lilies* in the conservatory this year; they are now in full beauty, and will continue so some time longer (we do not have them under glass except for a few weeks in the spring when they are starting into growth; they have the shelter of a cold frame until the shoots come in contact with the glass); as the flowers fade we either place them in a vinery or place the pots on their sides out of doors until the leaves turn yellow and fall off, when we shake the roots out of the soil and repot them. *L. auratum* requires to be carefully handled, and the bulbs should not be disturbed more than is necessary. It is more tender than any of the other sorts, and will not do well if the pots are saturated with water in the autumn. Of course we do not mean by this that it is not hardy, as it stands out all the winter in the Rhododendron beds, and flowers well every year if left undisturbed.

We were rather late this year in putting in the cuttings of *Phlox decussata*, the autumn-flowering herbaceous species. Many of the plants in 5-inch pots are now flowering, and are also useful in the conservatory. *Double Zonal Pelargoniums* are doing good service. The plants we have are now adorned with the finest trusses we have yet seen. The cuttings were put in late in the autumn last year in boxes, turned out of the boxes in the following March into 4½-inch pots, and shifted at midsummer into others 7 inches in diameter. Victor and Marie Lemoine are the best two; the former is scarlet, and the latter a soft clear rose. What about the double white sent out in the spring at a high price? We attend as many flower shows as most people, but have not yet seen it exhibited. We looked over the plants and removed all decaying leaves and flowers. In the case of the double varieties the trusses soon become unsightly if decaying flowers are not immediately removed from the centres.

In the stove a night temperature as near as possible to 65° is maintained. A lower minimum would suit some plants, but would not be beneficial to *Nepenthes* and some of the *Orchids*. We have looked over the *Orchids*, washed those requiring it with soft soap and water to remove insects; and in the case of such genera as *Vanda*, *Saccolabium*, &c., have surfaced the pots and baskets with fresh sphagnum. Our cool *Orchids* have been in a cold frame under a north wall until now; they were placed there early in June. They have now been removed to the house, where they will remain all the winter. Amateurs and others only having a small extent of glass should know how easily these fine plants can be grown. *Odontoclossum crispum* (Alexandre), *Mastodia Harryana*, and many of the finest species are as easily grown as *Pelargoniums*. Plenty of moisture in the atmosphere and at the roots is all they require.

FLOWER GARDEN.

Owing to the heavy downpours of rain and chilly nights the plants in the flower beds are not looking so well as they did a few weeks ago; we are careful, however, to make the best of them, as if the flower beds are allowed to become untidy through the accumulation of decaying leaves and flowers, it is a continual reminder that summer is over. The wet weather has caused *Verbenas* to make young growths, so that we shall be able to obtain cuttings suitable for striking in a week or two. At the same time all the other bedding plants will be put in, such as *Cuphea platycentra*, which is seldom grown now, but is a very distinct and pretty plant for the flower border. *Salvias*, *Heliotropes*, *Alyssums*, and other subjects of a like nature are put into a dung-frame from which the heat is almost gone. *Fansies* sown early in August have been planted out in boxes, the plants about 3 inches apart; they are now strong, and will be planted out in permanent beds as soon as the ground is ready for them. *Roses* have given a very good second bloom this year, but mildew has been prevalent, and has caused it to be not so good as it would otherwise have been.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

T. Bunyard & Sons, Maidstone, Kent.—*Select List of Dutch Flower Roots.*

Milligan & Kerr, Dumfries.—*Select Catalogue of Dutch Flower Roots, Fruit Trees, Roses, &c.*

Hooper & Co., Covent Garden Market, W.C.—*Catalogue of Autumn Bulbs, &c.*

W. Rollisson & Sons, Tooting, London, S.W.—*Catalogue of Cape, Dutch, and other Bulbs, Roses, &c.*

R. Parker, Exotic Nursery, Tooting, Surrey, S.W.—*Catalogue of Hyacinths and other Bulbous Roots, Alpine and Herbaceous Plants, Fruit Trees, &c.*

Ant. Roozen & Son, Overveen, near Haarlem, Holland.—*Catalogue of Hyacinths, Tulips, Crocus, and other Dutch and Cape Bulbs.*

Barr & Sugden, 12, King Street, Covent Garden, London, W.C.—*Autumnal Descriptive Catalogue of Bulbs and Plants for Winter, Spring, and Summer Flowering.*

Dowrie, Laird, & Laing, Stanstead Park, Forest Hill, London, S.E., and 17, South Frederick Street, Edinburgh.—*Descriptive Catalogue of Dutch Flower Roots.*

Dick Radclyffe & Co., 129, High Holborn, London.—*Autumn Catalogue.*

Sontag & Co., 1772, Folsom Street, San Francisco, California.—*Wholesale Catalogue of Californian Tree and Shrub Seeds.*

TO CORRESPONDENTS.

* * We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

AMERICAN BRAMBLES (*J. G. B.*).—The kind to which you refer must be the New Rochelle or Lawton. Apply to some of our leading nurserymen, who could, no doubt, procure it.

BRIDAL DOUQUETS (*Constant Reader*).—You may obtain them at any price, from half a guinea to five guineas and upwards.

BACK WALL FOR LEAN-TO VINERY (*J. C. H.*).—The best and cheapest substitute for brickwork for the back wall of a lean-to vinery, is a strong framework of deal scantling, faced inside with match-boarding, and outside either with weather-boarding or slates, filling the hollow space with dry sawdust.

HEATING A PIT (*Puzzled*).—A pit in three divisions for Melons, Cucumbers, and other plants cannot be heated with efficiency by a single furnace and flue. Cut through the old flue at the partition of 1 and 2, continuing the part in No. 1 around that division, or else causing it to return upon itself to a suitable shaft near the furnace, which should, of course, be outside the pit. Deal with the flue in the other divisions in a similar manner, making another furnace for it, and you will not only be able to apply heat to your Melons and Cucumbers without affecting the plants in No. 1, but you will avoid the great waste of heat, and therefore of fuel, that is quite unavoidable with your present faulty apparatus.

WHITE SCALE ON ACACIA ARMATA (*F. M. M.*).—The branch you enclosed to us is attacked by the white scale, which is not easy of destruction. We have found placing the plants out of doors after the growth is complete, and allowing them to remain exposed as long in autumn as is safe, a good mode of freeing the plants of this pest. Another method is to syringe them with water at a temperature of 110°, the surface of the pot being covered with moss about 3 inches thick, and over this some canvas large enough to

cover the pot, which canvas must be slit up the centre to the stem of the plant and secured to it, and also around the rim of the pot, the object being to keep the hot water from reaching the roots. Laying the plant on its side, syringe it well with water at the temperature above named, turning the plant over and over again, so as to reach all the parts with the hot water. This repeated a few times will soon rid the plants of the pest. It must not be dipped in the water, but have it syringed on.

PRIMULA JAPONICA LEAVES INJURED (G. C.).—The leaves are eaten or perforated by some caterpillar or weevil, which you may probably find at work if you examine the plants after dark with a lantern: or dust the plants with snuff or tobacco powder both on the under and upper sides of the leaves. We should remove the plants to a cold frame, plunging the pots in ashes to the rim, and give air freely in mild weather.

PEA CULTURE AND SELECTION (Amateur, Dublin).—The average duration of the Pea season is about four months, or from June to September. Occasionally they may be had at a somewhat earlier or later period, but not with any degree of certainty. The following selection may be depended upon for a good succession, sowing them in the order in which they are named. Laxton's Alpha, Kingealer, William L., Champion of England, Ne Plus Ultra, British Queen, Premier. Monthly sowings to be made in January, February, and March, and fortnightly sowings in the next three months. Two or three later sowings of Alpha and Kingealer may be made with good results in a favourable season.

APPLES AND PLUMS FOR SUCCESSION (Orchardist).—*Dessert Apples.*—Red Joannette, Irish Peach, Early Harvest, Reineette Jaune Hative, Devonshire Quarrenden, Kerry Pippin, Ross Nonpareil, Pitmaston Pine Apple, Margil, Pine Golden Pippin, Wyken Pippin, King of Pippins, Golden Reineette, Cox's Orange Pippin, Old Nonpareil, Scarlet Nonpareil, Golden Pippin, Boston Russet, Ashmead's Kernel, Cornish Gilliflower, Reineette Van Mons, Court of Wick, Calville Blanche, Pitmaston Russet, Melon Apple, Hubbard's Pearmain, Mannington's Pearmain, Keddleston Pippin, Reineette du Canada, Lord Burghley, Sturmer Pippin, Golden Pippin, Lodge-more Nonpareil. *Kitchen Apples.*—Manks Codlin, Hawthornden, Duchess of Oldenburgh, Cox's Pomona, Beauty of Kent, Cellini, Gloria Mundi, Lord Suffield, New Hawthornden, Mere de Menage, Adam's Pearmain, Afrifrust, Striped Keefing, Bedfordshire Foundling, Brabant Bellefleur, Northern Greening, Bess Pool, Gooseberry. *Dessert Plums.*—Royale Hative, Green Gage, Demiston's Superb, McLaughlin's, Kirke's, Purple Gage, Bryanston Gage, Cox's Golden Drop, Late Rivers. *Kitchen Plums.*—Victoria, Mitchellson's, Prince Englebert, Gisborne's, White Magnun Bonum, Cox's Late Reil, Shropshire Damsel. The whole of the foregoing kinds of fruit are arranged in the order of ripening.

GERANEACEOUS PLANTS (G. Yvatan).—We know of no work devoted to the description. "The Cottage Gardeners' Dictionary" includes them, detailing the description, management, &c.

SHRIVELLED GRAPES (G. A.).—They indicate deficient root-action; the roots are too dry, probably. We cannot give a decided opinion without more particulars.

GRAPES DISEASED (M. F. W.).—Your Grapes are shrank. Encourage more foliage by allowing the leaders and laterals of the Vine to lengthen, and apply fresh soil to the roots.

GRAPES MOLDY (B. M. of Co.).—They are destroyed by the well-known parasitical fungus, *Oidium Tuckeri*. The Vine should have been thoroughly and repeatedly dusted with flowers of sulphur as soon as the fungus was observed. Apply the sulphur now, and as soon as the leaves are off burn them, and lime-wash the whole house and Vine with flowers of sulphur in the wash. Then prune the Vine; again dust it with the sulphur, and next year look out in time for the *Oidium*.

STOVE IN GREENHOUSE (A Garden Novice).—If the gases arising from the mineral oil burnt in the stove you name can by a tube be conveyed into the open air, no injury will be caused to the plants, otherwise the gases will injure all, and kill some of them. Over so small a structure you might apply a cover at night, which would greatly aid in excluding cold.

CUTTING BOX EDGINGS (South Hants).—If cut or clipped every year it is best done during moist weather in June, and if much of the Box is to be removed it should be cut during moist mild weather in April or early in May.

LAKE GOOSEBERRIES, STRAWBERRIES, AND RASPBERRIES (Thos. Thomas).—On your light soil you will need to manure heavily, and mix it well with the soil in trenching, or it may be placed between the top and bottom spit, and the surface should be enriched by surface-dressings. *Gooseberries:* red—London and Clayton; yellow—Catherine and Lovell; green—Shiner and Stockwell; white—Autographist and Queen of Tramps. *Strawberries:* Dr. Hogg and Cockscumb. *Raspberries:* Carter's Prolific and Yellow Antwerp.

PROPAGATING BEDDING PLANTS, GOLDEN FEATHER PYRETHRUM (J. F. C.).—The propagation of bedding stock may be deferred till the first week in October, provided you can then afford a lively temperature, and guard carefully against the effects of damp. We would, however, remind you that severe frosts occasionally prevail before that period. Do not hastily discard the Golden Pyrethrum, we have no substitute for it of equal excellence. As you wish for variety, we recommend *Mesembryanthemum cordifolium variegatum* and *Polemoniumeruleum variegatum*, both distinct and excellent plants. *Stellaria graminea aurea* is of very dwarf habit, and has golden-coloured leaves. There are some good circles of it in Hyde Park.

MOSSY GROWTH ON A DOG ROSE (M. C.).—It is caused by Cynips rose, also called *C. Belegaris*, and *Rhodites rose*, one of the Gall-forming insects. It deposits its eggs in a bud of the young shoots of the Dog Rose and Sweet Briar. The grubs or larvae hatched from these eggs produce those galls, or lumps, covered with green and reddish fibres looking like moss, so frequently found.

ROYAL VINEYARD GRAPE NOT SETTING (L. Lonsdale).—If you examine the small berries you will find no stones in them, but in the large berries you will. When the flowers are expanding you should shake each bunch gently every morning about ten o'clock. It sets well with us treated in this way. Occasionally we draw our hand gently down the bunches, as a small globe of moisture gathers on the stigma of this sort, and unless removed fertilisation cannot take place.

GRAPES CRACKING (Novice).—Two correspondents complain of this. It is caused by too much water being applied to the roots either naturally or artificially at the wrong time. If the Vines are moderately dry at the roots when the Grapes are swelling for the last time, and they are well watered, in numerous instances, though not always, many of the berries will crack.

SELECTING SEED POTATOES (Idem).—It is not a good plan to select the small Potatoes for seed. Medium-sized well-shaped tubers should be selected.

We spread ours out on the floor of a loft to dry them, and if convenient leave them there until planting time.

FIRE AND WINDOW IN FRUIT ROOM (A Constant Subscriber).—We would certainly have a window in the fruit room, and a fire is necessary to keep out the frost. We use a small stove in our fruit room, and have not yet seen one better adapted for the purpose. It is in the form of a cylinder, is made of strong sheet iron, and is 21 inches deep by 6 wide. Patent fuel is used; it is only charcoal prepared in a special manner. The stove is registered as Joyce's patent, and is made at 255, Oxford Street, London.

TRAINING CORDONS (E. L.).—Train the cordons as you propose.

DWARF ROSES (Idem).—The strong young shoots which are thrown up from the base of Hybrid Perpetual Roses, as a rule should not be pinched back, as the shoots will produce a cluster of flowers. Cut away a portion of the old wood annually to prevent the bush from being crowded. The best time to do this is in February or March.

WINTERING BEDDING GERANIUMS (Idem).—Cuttings struck in August will keep better through the winter than old plants with your limited accommodation. It will require much care to preserve even the young plants in cold frames. We have answered the maximum number of questions; you should not ask more than three. Write again, and say for what purpose you require the plants.

FILBERT (G. A.).—The common Red-skinned Filbert, to be had of any nurseryman.

SEEDLING VARIEGATED GERANIUM (W. W. W.).—There is a variegated *Stella* in commerce very similar to the leaves you have sent.

NAMES OF FRUITES (E. Pond).—*Borovitsky (Centurion).*—The Apple is Duchess of Oldenburgh. (*R. L. E.*)—No. 1 is the White Summer Calville; No. 2, Sugar-loaf Pippin. Dr. Hogg would be obliged by grafts of the former in autumn.

NAMES OF PLANTS.—We again have to state that we cannot undertake to name Ferns without fruit, or from small portions of a frond. (*J. H. B.*)—See above. Your Geranium is a florists' variety. (*M. R.*)—See above. (*T. S.*)—A monstrous form of *Silene Armeria*. (*J. B. M.*)—Ferns shortly. (*C. L.*)—*Maurandya Barclayana*. (*T. u-years Subscriber*)—The white one is a double-flowered variety of *Hibiscus syriacus*, the *Althea frutex* of gardeners; the other is some near ally, which we cannot determine from specimen sent. (*T. P.*)—1, *Solidago Virgaurea*; 2, *Saponaria officinalis*. (*A. D. No. 6.*)—It is the *Potium Sanguisorba*, Lesser Burnet, or Salad Burnet. It is thus noticed in our "British Wild Flowers":—"The name is Gaelic, and refers to the brown colour that so markedly tinges the superior parts of the plant. Jamieson in his Scottish Dictionary quotes a couplet from Douglas's translation of Virgil, where Burnet is employed as the name of a brown colour.

"Behaldam thame so many divers hew,
Some peirs, some pale, some burnet, and some blew."

It is synonymous with the French brunette; and in Anglo-Saxon there is the Brun-wyrt, or Brown-wort. The leaves when bruised smell and taste like the paring of a Cucumber. Gerard says, "It is pleasant to be eaten in salads, in which it is thought to make the heart merry and glad; as also being put into wine, to which it yeeldeth a certain grace in the drinking." It is certain that the leaves and seeds are mildly astringent, and have in modern days been employed as a remedy in dysentery. It forms a herbage relished and beneficial to sheep and cattle." (*T. P.*)—We cannot undertake to name plants by leaves only.

POULTRY, BEE, AND PIGEON CHRONICLE.

CHICKENS FAILING IN AUTUMN.

SMALL marvel if, when human beings are bothered about their costume, when the thermometer falls 22° in twenty-four hours, that fowls, having no variety of wardrobe to go to, show the rapid change by unmistakable signs of having caught cold. For many years at this season we are inundated with letters telling us that chickens that have hitherto been lusty and growing, have all at once become dull, that their combs are dark, that they turn from their food and appear to give up. Writing in THE JOURNAL OF HORTICULTURE, we always shudder when we approach a subject akin to flowers, shrubs, trees, or even vegetables—we fear to commit ourselves. Nevertheless, it strikes us they feel the first change in the weather just as certain plants do, and as the first frost nips the Geraniums, Nasturtiums, Heliotropes, and all of that nature, so the chickens used to the glorious sun and the dry grass feel the absence of the one and the damp of the other. The simile may be continued: as we in the heat of summer sit with doors and windows open, but on the approach of winter, or at the first change of temperature, close first the door, then the windows, and at last light the fire, so the chickens require more shelter and better food. We breed many hundreds of chickens, and up to this time they always roost out. In past years, September has been a hot month, we have found the first fortnight in that month among the hottest times of the year. This year there is a change; half the human beings have caught colds, so have the chickens. We increase the quality and the quantity of the food. We catch them at night when at roost, and put them in the houses they are henceforth to inhabit. We are sorry to see a growing disposition to feed on rice and potatoes. Both are bad. The first induces poverty of blood and low condition; the second invariably produce disease of the liver, causing that which is known as a great delicacy, the "foie gras." However delicious it may be when it has passed through the hands of the "artists" at Strasburg, it is by no means a pleasant symptom among the inhabitants of a farmyard or a cottage poultry-yard.

The best food for poultry is ground oats; but that does not mean the ordinary oatmeal. It means the whole of the oat

ground with stones dressed for the purpose, so fine that the husk and corn form a smooth dour that will when wetted work into a paste or liquid. The ordinary ground oats when slaked with water mix as though they were made-up partly of chaff. Fowls will not eat this latter, but they are greedy for the former. They do better on it than on any other food. It makes the best morning and evening meal. The midday one may be Indian corn or whole barley; or, better still, the scraps from the house, pieces of fat, the meat from beef-tea or mutton broth; the dry skin of any joint, the knuckle of shoulder or leg of mutton chopped small and thrown down, are all excellent food. For small chickens these may be added to chopped egg, bread and milk, and such like. They will not grow so fast as their predecessors have done. The nights are getting longer, the days shorter, the sun has less power. The difference is not felt so much in the middle of the day, but the mornings and evenings are cold, they require to be fed at dawn and sunset, and these two meals should be the best of the day. All chickens that have not left the hen, or those that do not yet roost with the adults, should be got under cover every night. Exception may be made sometimes in favour of the hens under ribs, but they should be so placed that they are safe from cold winds and driving showers. It will likely be said, Thousands of chickens are reared without all this trouble; granted, but we only hear of the survivors, and know nothing of the unfortunates who die in the process. Our object is to give such advice as shall prevent disappointment. We feel sure we have done so, and we have endeavoured to carry out our unvarying rule of making all plain, and advising only that which we have ourselves tried.

PUBLISHING JUDGES' NAMES.

I AM also of Mr. Wright's opinion that Judges' names should be published before the closing day of the entries, and of late I have taken the determination not to show unless I know the gentlemen's names who are to officiate. My reason for so doing is simply because the opinions are so different. For instance, I have a pair of birds of a certain class which I have shown with great success under several good Judges—the same birds have been entirely passed over by other well-known gentlemen, whereas birds I do not like in certain points took the honours; and as I have birds of the same class to suit those gentlemen also, I can suit them all.

I do not mean to intimate that the latter Judges are not efficient gentlemen, only their opinion differs, and they prefer certain points the former reject, and *vice versa*.

In answer to several letters I wrote to secretaries of shows a few days before the entries closed, the schedules being published too long beforehand to mention the Judges' names, I always had for reply that the committee were not quite decided as to their selection, but that gentlemen of well-known character were sure to officiate; and the consequence was that they lost my entries. My opinion is, that if committees cannot publish the Judges' names with their schedules, they should do so through the Journal as soon as they decide.—A. A. VANDER MEERSCH, *Tooting*.

ALTHOUGH I never exhibit fowls I take great interest in them, and on perusing Mr. Wright's letter in your last week's Journal, it appeared to me that publishing the Judges' names at poultry shows would in no way assist breeders to attain the desired knowledge—viz., the proper standard to aim at in breeding for exhibition, but that whilst Judges held such diametrically opposite opinions as those mentioned in Mr. Wright's letter, it would simply tend to start two or more classes of the same breed, each said to be perfect specimens, according to whichever Judge they chose to follow. This I consider would undermine much already accomplished. In my opinion the remedy would be for all Judges to award by one recognised standard, then I should say that most of the in-and-out judging now complained of would be done away with.—SPECTATOR.

WITH reference to, and in connection with Mr. Wright's communication on page 181, I would direct the attention of poultry exhibitors and breeders to another matter which appears to me to be of paramount importance. Of my own knowledge, more dissatisfaction arises from the incompetence or peculiar fancy of the Judge than from the mistake of an admittedly good Judge, an accident which distresses the Judge fully as much as the losing exhibitor. But why should there be any difference of opinion between really good Judges? or why should any point be left to their fancy? To me it appears most anomalous, that such a number of persons should be found willing to submit their birds to competition and adjudication when there is no recognised standard of excellence to bind the Judge. It is not only very convenient for Judges that there is not such a standard, and that many points should be left to their taste or discretion, but it is eminently unsatisfactory to exhibitors, unless, perhaps, to those favoured few who know exactly what the Judge likes, and naturally take advantage of the knowledge; but it is equally

convenient to unconscientious persons who, when getting rid of their faulty birds, are ever ready to shield themselves under the pretence of "disputed points."

Judging at poultry shows will never give anything like general satisfaction until there is a recognised standard of excellence—a standard, too, in which the points will be much more numerous and with a higher figure set to each than in the old standard. Armed with such, amateurs would soon be sufficiently skilled to deal with experts, and any intelligent fancier after a year or two's experience might give satisfaction as a Judge. Besides, a recognised standard would have another merit—it would keep points from shifting, a matter which causes much annoyance at present. If what I have endeavoured to set out above is true, it surely would not be expecting too much of the gentlemen who are at present at the head of the list of Judges, to sink any differences of opinion that may exist between them, and unite in publishing a standard which, I have no doubt, would be hailed as a boon by every true poultry fancier.—O. P. H. Z.

DEALERS AS EXHIBITORS.

THE letter which appeared a few weeks ago from the pen of Mr. L. Wright was read with much interest and attention by all poultry exhibitors, and must have carried conviction to the minds of every disinterested and impartial observer of the controversy. Merit is the one thing needful, whether in the pen of the dealer or amateur, at our poultry exhibitions, and merit ought to and must bear off the palm of victory. By excluding dealers from exhibiting, in most cases if not in all we should be excluding merit also; but at the same time it is an incontrovertible fact that when they do exhibit they are sure to take almost all the prizes, "for what is the use of showing," as "OBSERVER" truly said, "when Mr. Fulton is sure to be there?" One way of moderating, if not removing the grievance, would be to confine each exhibitor, be he either dealer or amateur, to only one entry; for then amateurs, knowing that they would stand some chance of obtaining at least a second or third prize, would take courage and send their birds, and thus the number of entries would be largely increased. Although at first sight this plan would seem to injure the pocket of the dealer, yet in the long run he would be a gainer. He would be able to transact much more business than he does at present, and the increase in the returns of his business would amply compensate for the loss he would sustain by not being able to take more than one prize. The greatest amount of dissatisfaction and grumbling is caused, not by dealers exhibiting, but by their carrying all the prizes away.—A. T. W.

ALDBOROUGH AND BOROUGHBIDGE POULTRY SHOW.

THE pretty little town of Boroughbridge was *en fite* on August 22nd, when the Show was held, and the receipts at the gate were just double the amount taken last year. The poultry on the whole were very good, but the adult birds showed the effects of the season in their ragged plumage. *Dorking* chickens were a very good class. The first-prize pen had only the advantage of age to secure its position, the second being in many respects better, but much younger. *Spanish* were a treat to see. The first-prize cock was in splendid condition, his face being so white and smooth. In *Brahma* chickens a pen of very fine Lights secured the first honours against their darker brethren, and if they are kept growing will be difficult to beat. In the Variety class a splendid pen of Crève-Cœurs, very large and in good condition, were first, and Black Hamburgs second.

Turkeys and *Geese* were very large and good, and the Aylesbury *Duck* classes such as we seldom see at the largest shows. In the Variety class *Widgeons* were first, and *Muscovy* second.

Pigeons were very good, the most noteworthy being the Carriers, Trumpeters, and English Owls. The prize *Rabbits* were all Lops with good ears, which measured well.

We published the awards last week.

ALFORD POULTRY SHOW.

Few committees can boast of so successful a first attempt at carrying out a poultry show, every attention being paid to the most minute detail that could ensure popularity. Two very large tents were provided, the one being devoted exclusively to poultry, the other containing a well-arranged display of Parrots, Cage Birds, Rabbits, and domestic Cats. The latter portion of this collection was much improved in appearance by Mr. Billett providing with the pens a bright-coloured plush ottoman for each cat, which in every instance formed a favourite and very comfortable resting place for the animal exhibited. Unfortunately it proved very wet early in the morning of the 2nd, but as the day wore on the clouds broke, and a bright sun soon rendered everything as pleasant as possible. A general feature of the Show consisted in the majority of the old birds, from

moulting, being in woeful show trim, but the great bulk of the chickens were not only well grown, but also in admirable feather. For this simple reason we must confine our remarks more particularly to chickens.

Among these a grand pair of Brown Red *Game* claim especial mention; they were shown in the hardest feather, well matured, and the cockerel only very recently dubbed. Mr. Tickner, of Ipswich, was successful with a pen of Golden-pencilled *Hamburgs*, sent in exquisite condition. In the *Cochins*, both White and Partridge-feathered were very excellent, but the Buffs were as decided inferior. A very well-feathered pen of Brown *Lophorns* were much noted, as being so rarely met with; and a very strange-looking pen of White chickens, the product of a cross between the true Frizzled and Silky fowls, were decidedly a curiosity, though as yet barely ready for public exhibition. The show of Aylesbury *Ducks* contained many very large specimens, but faulty bills were the rule. The Rouen *Ducks* were a very fine class, but, strange to say, no fancy waterfowl were exhibited.

Pigeons were a fair collection, but not numerous; White Pouters, Black Carriers, Foreign Owls, and very superior Barbs, being among the most prominent varieties.

The finest breed of *Rabbits* shown were the Lop-eared ones, though some specially good Angoras and Silver-Greys were in general competition in a class open to all other breeds.

A very attractive portion of the Show consisted of Parrots of many rare varieties, singing birds both foreign and British, and a very interesting couple of Long-eared British Owls. These Owls were soon claimed, as, being shown in the most perfect feather, and from their rarity in confinement, they will doubtless be transferred to some public collection.

Poultry and Pigeons were judged by Mr. Edward Hewitt, of Birmingham; and Mr. J. W. Harrison, of Spalding, awarded the prizes in all the remaining portions of the Show.

HYDE POULTRY SHOW.

The great feature of the Hyde Show was its general excellence. Nearly the whole of the most noted prize pens were entered, but some were not by any means in perfect feather, as they were moulting heavily. A somewhat serious drawback caused some pens to arrive too late for competition. By the 7.55 A.M. train from Manchester a considerable number of entries were expected, both of dogs and poultry, and it was arranged for the Judges to arrive by the same train. At the Hyde Junction, however, an accident occurred; the engine, tender, and a portion of the wheels of a first-class carriage leaving the rails at what are called the "facing points;" and the engine embedded itself to the very axles, and entirely blocked both lines for about four hours. Except the fright consequent on a great noise and heavy jolting, the passengers, as well as the poultry and dogs, were none the worse for the mishap, and, under the circumstances, permission was granted to the Judges to walk down the line a mile and a

half to Hyde to fulfil their duties, whilst the Committee, with praiseworthy dispatch, sent conveyances by road for those unexpectedly delayed on the railway.

The birds were nicely penned around the walls of a mill, but the light being what is called a "back light"—that is, coming through the pens at intervals from the windows behind the pens, could not display the poultry to the best advantage. The *Cochins* and the *Erahmas* were admirable, and of *Hamburgs* very rarely has there been such display. The *Game* were few, but really good. *Bantams* were a fine collection, a pen of real Silver-faced ones being worthy of note. *Geese*, *Ducks*, and *Turkeys* were all that anyone could desire. The comfort of the whole of the poultry was well provided for.

DORKINGS.—1, J. Robinson, Garstang. 2, J. Walker, Rochdale.

COCHINS.—*Engl and Cinnamon*.—1 and 2, W. A. Taylor, Manchester. *Any other variety*.—1, W. A. Taylor (Partridge). 2, T. Aspdon, Church (Partridge).

TODMORDEN POULTRY SHOW.

The fourth annual meeting of the Vale of Todmorden Agricultural Society was held on the 6th inst. The entries, considering that it is so late in the season, were very good in all departments; in poultry and Pigeons they amounted to about 350. The management of all was exceedingly good, and the pens, which were on Turner's principle, placed in single tier looked exceedingly well, while the birds appeared quite comfortable.

Game were divided into five classes, and all were young birds, some of which were very good; among them were the first-prize single Brown Red cockerel and the pair of Brown Reds. In single pullets a grand Pilo was first, closely run by a capital Brown Red. The only other birds worthy of special notice were the first-prize Duckwings, which are, doubtless, one of the best pens that have been shown of late. The only exception in the age of the fowls was in *Brahmas*, of which there was one adult class containing some good old birds, and the young birds were also very good and forward. In *Cochins*, Buffs were first

and Partridge second. *Dorkings* were a good lot, but the oldest chickens were much out of condition, the first-prize pen being young, but very good in all particulars, and all were Dark Greys. The first-prize *Spanish* were forward and in good condition, but the rest very late. Golden-pencilled *Hamburgs* were very good, forward, and in brilliant plumage; but some of the best birds in this section were the Golden-spangled, especially the pullets, which may fairly be termed perfect. Silver-pencilled were not so numerous, but the two winning pens were very good and close in point of merit. The first-prize Blacks were *Hamburgs* in all points, and such as will be difficult to beat. Of *Bantams*, Game were a good lot, the first being Black-breasted Red, the second Pile, and a very handsome pair of Brown-breasted Reds were highly commended. In the next class were but two noteworthy pens, the first being pure white-ground Silver Sebrights, and the second Blacks. In *French* only the first-prize *Crève-Coeurs* were of any note, but these were forward and good. With the exception of the Malays, in the Variety class it was difficult to find a pen fit for the prize, but these were a grand pair.

Ducks in all classes were exceedingly good, the *Aylesburys* being of immense size and of the purest quality, and every pen was noticed, as also most of the *Rouens*. In the Variety class for Ducks the first were *Vidua* Whistlers, and the second *Brazilian*. *Geese* were a grand lot, Greys being first and Whites second; and the *Turkeys* were large, but sadly out of feather.

The poultry in the district competition was very good in some of the classes, the *Cochins* and *Game* being among these; and in Ducks three prizes were awarded, the first being for *Rouen*, the second for *Aylesburys*, and the third for *Black East Indian*.

The *Pigeon* classes were well patronised, but in some the birds were only of ordinary merit; this remark applies to the *Pouters*, with the exception of the first-prize Reds. In *Carriers* Duns were first and Blacks second, and the *Almond Tumblers* were pretty good. In the next class for *Tumblers* *Black Mottles* were first and *Blue Beards* second, both pairs being *Short-faces*. *Fantails* were only of ordinary merit, but the *Dragoons* were a fine class, the two winners being *Blues*, and embodying all the grand points of this variety. *Barbs* were good, Blacks being first and Duns second. There were three good pens of *Red Jacobins*, but the rest were very poor. *Antwerps* were a large but irregular class, both pairs of winners being Duns, the first *Short-faces* and the second large useful *Long-faces*, while there were many good pens faulty only in eye, which was of a sickly yellow. Of *Turbits*, only the winners good, and both pairs were *Blue*. *Trumpeters* were moderate. *English Owls* were a large class with few good pairs except the winners, the first being *Blue*, with capital heads, but somewhat small, while the second were *Silvers*, large, but not so good in head and gullet. *Foreign Owls* were good, *Blues* being first and Blacks second. Of the *Blue Rock* little can be said, except that they were all common dovecock birds, but the prizes were awarded. Of *Nuns* there were only three pairs, but good. In the Variety class *Black Brunswicks* and *Hyacinths* won the prizes.

The *Rabbits* were not numerous, the prizes, as in *Pigeons*, not being good, but some of the specimens were excellent. In *Lop-ears* the first was a *Grey-and-white*, 22 inches by 4½, the second being *Fawn-and-white*, 21 by 4½. *Angoras* were all good and well shown, and the *Himalayan* also a neat lot. The *Silver-Greys* were one of the best classes. The Variety class contained some grand Dutch, the first prize being awarded to a *Grey Rabbit* of that variety, and the second to a splendid *Belgian Hare Rabbit*; many of the others were highly commended.

GAME.—Any colour.—Cockerel.—1, W. Ormerod, jun., Todmorden. 2, W. Tillotson, Coates, Barnoldswick. Pullet.—1, C. W. Hetherley, Mablethorpe. 2, E. Dyson, Halifax. *he*, J. Mason, Worcester. *c*, W. Ormerod, jun.; W. Tillotson.

The Judges were Mr. E. Hutton, Padsey, and Mr. J. Dixon, Bradford.

KENT AND SURREY FANCY RABBIT SOCIETY.

The thirty-first half-yearly Show of the above Society was held at Mr. J. D. Allatt's, Montpellier Tavern, Walworth Road (near Walworth Road railway station), on the 8th inst., when some very fine specimens were exhibited. A handsome silver cup of the value of five guineas was given for the longest-eared Rabbit. The following are the awards:—

Prize.	Length	Width	Age	Weight
1st. Mr. Jennings. Black-and-white Doe (Silver Cup)	23	5½	4 21	5 10
2nd. Mr. Terry. Black-and-white Doe	23	5½	4 7	9 6
3rd. Mr. Hyatt. Black Buck	22	5½	3 12	9 0
4th. Mr. Staig. Black-and-white Doe	21	5½	5 10	6 0
5th. Mr. Woods. Yellow-and-white Buck	21	5	4 5	6 0
6th. Mr. Mihill. Tortoiseshell Buck	21	4	7 14	8 0
7th. Mr. Woods. Blue-and-white Doe	21	5	3 21	7 0
8th. Mr. Woods. Grey-and-white Doe	21	5	5 3	9 0
9th. Mr. Byford. Grey Doe (Self-colour)	21	5½	6 23	8 0
10th. Mr. Terry. Blue-and-white Doe (Weight)	21	5	7 0	9 10
11th. Mr. Inman. (Dutch) Blue-and-white Buck and Doe (Best Foreign of Any variety).				

JUDGES.—Messrs. Byford, Heath, and Hyatt. Supernumeraries, Messrs. Jennings and Clark.—W. H. Webb, Secretary, 115, Albany Road, Camberwell, S.E.

INGENUITY IN A PIGEON.—The following facts (having been witnessed by myself) may, perhaps, be considered worthy of insertion in your Journal, as bearing on the subject of "Perception and Instinct in the Lower Animals," which has lately been brought into such prominent notice. On the Richmond Road (Surrey), at about a mile from the town, stands an old roadside inn, except "The Black Horse," owned by one R. Ketley. Attached to the house are a number of domestic Pigeons of various breeds, chiefly Pouters. Having occasion to wait for my pony to be harnessed at this inn a few years since, my attention was directed by a gentleman, a resident of the neighbourhood, with whom I was acquainted, to the strange conduct of one of these birds. A number of them were feeding on a few oats that had been accidentally let fall while fixing the nose-bag on a horse standing at bait. Having finished all the grain at hand, a large Pouter rose, and flapping its wings furiously, flew directly at the horse's eyes, causing that animal to toss his head, and in doing so, of course shake out more corn. I saw this several times repeated; in fact, whenever the supply on hand had been exhausted. I leave it to your readers to consider the train of thought that must have passed through the

Pigeon's brain before it adopted the clever method above narrated, of stealing the horse's provender. Was not this, indeed, something more than mere instinct? — RICHARD H. NAPIER, *Upton Cottage, Bursledon, Southampton.*—(Nature.)

BEES AT MANCHESTER SHOW.

THE bees and honey at this great Show were for four days surrounded by an admiring and ever-changing crowd of people. Indeed, the masses of visitors were so great during the last two days of the Show that not one in six could come near the bees. Perhaps the most meritorious thing produced in the whole Exhibition, including fruit, vegetables, &c., was a Crystal Palace of honeycomb weighing 87 lbs., belonging to Mr. Breen, of Arwick, Manchester. It took the first prize offered for the best glass super. Mr. Pettigrew called it a Crystal Palace, and valued it at £10: and one of the Judges bought it on the spot at that price. Several excellent glass supers were exhibited, one weighing 40 lbs. took the second prize, it was owned by Mr. Bethell. The wooden supers were not quite filled. Mr. Withnell, of Burton-on-Trent, came to the front here, and Mr. Lee, of Bagshot, took the second place.

For the heaviest and best hive filled by a swarm of this year Mr. Breen, of Manchester, took the first prize with a Pettigrew hive weighing 84 lbs. and Mr. Withnell came second with a bar-frame hive. For the most ornamental hive Mr. Cooke, of Denton, near Manchester, took the first prize and Mr. Wrigley, of Rochdale, came second; and Mr. Young, of Burton, had the best observatory or unicomb hive.

Two medals were offered for the best collections of empty bee hives and supers and bee furniture. Mr. Lee, of Bagshot, with a very neat and unique collection carried off the highest medal; and Mr. Yates, of Manchester, took the second medal. Extra prizes were awarded to Mr. Wood for a collection of bee produce and bee furniture, sent from Denmark; and to Mr. Aston for drone traps, &c., which he brought from Shropshire.

Mr. Pettigrew, who did not compete, exhibited a live weighing 108 lbs. and a glass super weighing 28 lbs., both filled by a swarm obtained on the 21st of May; also a Crystal Palace of honeycomb 20 inches high, weighing 40 lbs. When Mr. Pettigrew suggested this bee and honey Show, he hoped to be able to place on the exhibition tables thirty or forty big supers with a view to give a stimulus and impulse to bee-keeping, but this season has been a most unfavourable one for honey-gathering in the neighbourhood of Manchester, indeed it is the worst for bees that has been there experienced for twelve years.

MOVING STOCKS, UNITING BEES, &c.

WE have had many inquiries of late in the pages of this Journal on the subjects indicated above, which leads me to offer a few hints as to the best mode of carrying out the several processes in question.

Let me begin with the moving of stocks, which not infrequently is a necessity at this time of year, as well as on or before Lady-day. To move bees without due precautions to more or less short distances is always a work of some peril, as the poor insects when not made acquainted with the change rarely find their way home again. They dart forth as usual—at least, all the older ones—without reconnoitering the new position of their hive, and after a day's, or a few hours', foraging, without suspicion of danger, they fly naturally to the old well-known stance, only to perish in their weariness, after a few flights hither and thither in the vain attempt to find their home again: therefore all care should be taken to give the bees some warning of the change before they leave the hive in the morning. This will reduce the risk of loss of their valuable lives; and the loss will be diminished in proportion to the care and pains taken. We think the following plan will be found to answer in every case and under all circumstances at whatever time of year the removal of hives takes place, and whatever be the distance to which they are carried. The principle can be adopted in the case of all hives of wood or straw. Prepare a shallow box, say 18 inches square and 2 or 3 inches deep. Let it have a bottom board with roomy entrance-way, and alighting-step in the usual place. Over it fix a large board if necessary, so as to be suitable for all your hives of whatever shape. Cut a sufficient hole in it towards one side in such a manner that the bees must pass down into the empty box below to get into the open air. The hole had better be so cut in the board as for its outer edge to fit with the side of the box over the passage into the outer air. In this way the bees will pass in and out with the least difficulty, and yet be arrested by the obvious change that has taken place in respect of their mode of exit. We should recommend the removal of each hive separately after an interval of a day or two.

As to uniting bees, one caution is of great importance. It is of no use attempting to unite hives in the same garden, save such as are side by side. You may very safely unite three or

four such stocks together, taking care to place the united stock in the centre of the lot. It is a good plan to approximate the hives that are to be united as near to each other as possible some days beforehand. The simplest method of union has been already given in replies to correspondents. It consists merely in driving the bees of two or more stocks into a common empty hive towards the close of the day, and then dashing them out on the ground in some open place close to and in front of the stock which has been chosen for their permanent dwelling. It must be borne in mind, however, that a valuable Italian queen must be hunted for (should such a queen preside over one of the stocks to be united), and given to the bees after their reunion. It is safest to give her to the bees in a queen cage, introduced from above among the combs. Of course the other queen or queens must be caught and destroyed after they have been driven into an empty hive. We are in the habit of dashing them out again and again upon the ground till we have secured the queen. We should not hesitate, however, to drive the hive with the Italian queen first, without catching her, and then, after driving and catching the other queens separately, unite them all by a final dash-out upon the ground. Some recommend, by way of further precaution, the sprinkling of scented syrup over the whole mass of united bees. This we think unnecessary, and at this time of year even dangerous, owing to the probability of its confounding the whole apiary by attracting robber bees from every quarter. All such operations should be done in the full daylight, although towards evening care is important, particularly when the bees are so poorly off for honey as they are now, for their scent and appetite for syrup of all kinds is at present unusually keen.

Feeding on a liberal scale, but always at night, should follow immediately after the union of hives has taken place; for as the consumption of honey is very rapid, at such times you might find your hive in a starving state before many days are over. But, indeed, no time is to be lost in feeding all weak hives that are designed to remain till spring, whether they be united stocks or otherwise. More than half the stock of bees in England will perish this autumn without immediate attention. Every effort should be made now to secure them effectually. Let there be no discouragement allowed. A series of lucky years may be drawing near, which will more than compensate for all losses and disappointments.—B. & W.

OUR FIRST "SWARMING."

NOT to experienced apiarians do I relate the story. I would humbly beseech rather that they please to not listen. But if among lady bee-keepers there be one who knows as little practically of "natural" swarming as did I on the morning of May 27th, 1873,

"To her my tale I tell."

The morning was cold, cloudy, breezy, and I said to my sister Nellie, as we rose from the breakfast table,

"We shall not be able to divide the bees to-day, I fear."

"Will it matter?" she asked.

"Oh no," I replied, serenely and confidently. "They will not think of emigrating under a week; their preparations are but just begun, and in cool weather they are better off as they are."

As the morning advanced the wind died away and the sky cleared. At noon it was bright, warm, and still. I noticed at this time that the bees at one hive were very quiet—scarcely a bee in sight—while at the other they were humming merrily. The first-mentioned being the strongest colony, I wondered a little at their inactivity; its real meaning was clearly apparent some hours later, especially after re-reading a forgotten passage from Langstroth—"If in the swarming season but few bees leave a strong hive when other colonies are busily at work, on a clear, calm, warm day, we may look with great confidence for a swarm, unless the weather proves unfavourable."

An hour or so after noon, thinking that the bees were making an unusual and unnecessary amount of noise, I stepped to the door to see that at this but recently so silent a hive, there was now quite a commotion. Many bees were whirling about and over the hive, while others were pouring forth in an unprecedented way as to numbers and hurry. Come forth in a very large stream they could not. The evening before having been cold and stormy I had shut the fly-holes and somewhat contracted the lower entrance; and as the morning had been cloudy and the bees quiet, no change had as yet been made. Now, as I stood gazing on them, spell-bound at my first surprise, there flashed across my mind the query, "Are they swarming?" But it was only to be at once dismissed. For didn't I know that they were not ready to swarm? Hadn't I looked into the hive but a day or two before, and found in the most advanced queen cell only an egg?

My second and accepted thought was this, that the sudden warm sunshine had given a general impetus to honey-gatherers and young bees to go forth, and that the unusually narrow doorway excited and troubled them.

Still there was no cessation to the steady outward flow, and in larger and yet larger circles around and about the hive. *Something* must be wrong!

"Nellie!" I cried piteously to sister in the next room, "I don't know what is the matter with my bees!"

She hurried to the door. "Why, they're swarming!" she exclaimed with decision.

That settled it. She spoke as one who knew, and my own rejected first impression came back with overwhelming conviction. They were swarming. What should I do?

I had no course of action marked out, because I had long before determined that my bees should not swarm. Most excellent care would I take to prevent that in these great woods, where, if they went beyond the clearing, it might be impossible to follow or to find them. I had a vision of them now, sailing off over the tree-tops beyond my reach, and I felt—I felt only that they must be stopped! now at once!

Suddenly I remembered to have somewhere read that the queen often does not come out before a third or half of the swarm has emerged. It was then possible, it might even be probable, that she was still in the hive. If so, she should either stay there or be captured at the entrance.

Seizing a pail of water I rushed forth hatless, veilless, and gloveless into the midst of the throng of runaways, and began sprinkling them as they emerged. But first, with curious and absurd inconsistency, seeing how much faster they wanted to come out than was possible, and pitying their crowded discomfort, I voluntarily bent down and opened a fly-hole, and so had two streams pouring forth instead of one. (Nellie will never forget, or cease to laugh at me for that performance, I fear.) They beat against my dress, they whizzed by my ears, brushed my hair, grazed my cheeks, but I stood my ground, trying to watch both openings at once for the queen, and sprinkling the water more and more copiously as I saw that it produced no effect. I was beginning to despair, for many bees were washed down, and I didn't care to drown them, much less did I wish to risk drowning my queen. Just then came a happy inspiration.

"Hand me that wide board, quick! quick!" I cried to Richard, who is a little afraid of bees. He cautiously shored it within my reach. Holding it so as to throw a shadow over the entrance I continued the sprinkling. The effect was magical.

"It is going to be something of a shower after all!" "The sun is under a cloud, and it rains faster than ever!" Telegrams of this import must have been sent through the hive in a twinkling, for all at once there was a sudden, an entire stop to the outward rush.

Then for the first I ventured to draw a long breath, and then, too, I began to question doubtfully, if it had not been a very foolish and useless, as well as an unsafe proceeding? Was the queen out or in? The bees that had been washed down were picking themselves up rapidly, and I soon became convinced she was not among them.

But over our heads quite an army of bees were whirling and swarming, now this way, now that. Once we accompanied them half way across the woods, then back to the vicinity of the hive. Suddenly they separated widely and came down to the ground, very evenly scattered over a large surface. I knew that they had missed and were looking for their queen, and I wondered if their anxiety could be half as great as mine. Rising again, they again seemed starting for the woods. But immediately returning, once more they sprinkled themselves far and near over the ground, somehow, Nellie suggested, giving one the ridiculous impression of "going down on their hands and knees" to make an effectual search. Evidently it was to them in some way a satisfying one, for all now rose as by one accord, and came hurrying back to the hive, pouring in as fast as possible, and covering the whole front with a black sheet.

So soon as all had settled, we lifted the hive from its stand, and placed an empty hive in its stead. Then, after arranging the frames and putting in two combs of brood and honey from the old hive, we (Nellie and I) began a careful search for her missing queenship. To our joyful surprise it was not a long search. We found her as composed and dignified in demeanour as though nothing had happened, and with very little trouble we transferred her to the new hive. We found several queen cells, the most advanced containing the tiniest of worms.

It was then, I think, that I for the first time discovered that I had forgotten my bee-veil. Of course I walked into the house for it at once.

The rest of the work, the appointment of the remaining bees—every bee was at home—was a somewhat perplexing business. However, I used all the judgment I had, and if the division was not made quite as well as the bees could have made it, everything has seemed to go exactly right with the new colony thus far. With the old colony, too, all was well until—but that belongs to another chapter.

Perhaps someone as inexperienced as myself may be interested to know that from first to last the bees were on their very best behaviour, nobody was stung.

We found a nucleus from the other hive the same afternoon;

and on the whole satisfactory as this experience had been to me, I felt no desire to repeat the same with another swarm, and in conclusion would say that I do not venture to take the responsibility of advising any lady bee-keeper to take the course of action above described.—(Correspondent, *American Bee Journal*.)

ROBBER BEES.

I SHALL be glad if you can inform me of any remedy to prevent robbers from entering my hives. I fed my bees last Saturday afternoon from the outside (not a good plan, as I have found out), and I think there must have been a stranger helping itself too, for a short time after they had taken it all in I saw them pulling one or two about on the floor-board, but I thought no more about it. On going to look at the bees the next morning I was surprised to find a great number outside guarding, and over a hundred that they had killed on the floor, and a few robbers trying to dart in through them. They have been trying to get in ever since. I have picked up the dead bees, and counted about 280. The robbers come from a person's apiary about a quarter of a mile off. I saw in last week's *Journal* about stocks dying in August of starvation, and I think his bees must be starving from the way they try to get in; they keep my bees from working, besides killing the others. I have made the holes smaller. Can anything else be done? What is the average weight to be allowed for a swarm with combs and stored pollen? To what age does a queen bee generally live?—P. RAINFORD.

[You have done right by contracting the entrances of your hives; but if the robbers still force their way in, you must make the holes so small that only one bee can get through at a time. If this do not prevent the attack of the assailants you had better remove your hives within doors for a few days, giving the bees plenty of ventilation, putting them back again on their old stands. Do not feed them while in confinement. It is very bad practice to feed in front of the hive, particularly at this season of the year. Are you sure that your own hives are strong in population? It is not always that starving bees are the worse robbers, but the strongest and best-provisioned colonies very often make war on their weaker neighbours. A stock should weigh from 15 lbs. to 20 lbs., exclusive of the hive, to make it safe for the winter, though it will sometimes do well with less. Queens may live four years, but probably three years is about the average duration of their lives.—EDS.]

METROPOLITAN RABBIT ASSOCIATION.—There is to be a grand show at the Montpellier on Monday, September 22nd, 1873, where all the metropolitan Rabbit societies have combined to show their best Rabbits against each other for a silver cup of the value of five guineas, besides several other money prizes. It is expected to be one of the best shows ever exhibited in London.

OUR LETTER BOX.

WINGS IRREGULAR (A. B.).—Many people suffer in the way you do. There is a twisted flight that is incurable, but we do not imagine yours to be one. We have several Brahma cock chickens, large well-grown birds, and after a run or any other exertion they drop their flights, but they always get them up again. The incurable case we mention above is hereditary. That of which you complain is often the result of weakness.

BRAHMAS WITH SWOLLEN FEET (H.).—Have the rough stones raked off the ground. The feet of fast-grown cocks are very tender, and their bodies are heavy. If you cannot rake the stones off choose some more favourable spot, and shut the cocks up by themselves. Anything is better than getting them humble-footed, which is sure to happen.

INFLUENCE OF PARENTS ON COMB AND LEO COLOUR (J. G. L.).—When two birds of different breeds are mated together, some of the produce generally present a mixture of both, while others are to all appearance pure specimens of the breeds to which their parents belong. You will, however, be able to choose chickens possessing the points you wish to perpetuate, and by mating them again to pure birds, you will probably succeed in breeding that which you want.

BANTAM WATERY-EYED (J. W.).—We hardly know what you mean by a watery eye. If there is any swelling with it, it is a cold, and should be seen to. The best plan is to wash it with vinegar and water, and to give a stimulant—some bread and strong ale, adding thereto a couple of pills of camphor, each the size of a garden pea. If it be only a watery eye we should still use vinegar and water.

EXHIBITING SILVER-GREY DORINGS (W. D.).—A class for "Coloured Dorings" comprises Silver-Greys, Cuckoos, and all but White. "Any other variety" should mean White. Where there is a class for Silver-Grey, the prize list generally states "Coloured Dorings other than Silver-Greys." As a rule, the Silver-Greys are not so heavy as the others, and the Whites may stand a good chance against them. Nine pounds is a good weight for a White Dorking cock, and 7 lbs. for a hen.

CHICKENS NOT FEATHERING (A Subscriber).—Your feeding is not good enough. If you have no grass run you must get some seeds of growing grass, like a lark's turf, only much larger; you must give them daily. Feed them on ground oats or barley-mead mixed with milk, some hard-boiled egg chopped fine, and bread crumbs soaked in milk. Leave off Indian corn, sharps, and rice.

COCKERELS AND CHICKENS FALLING (J. S.).—Boiled potatoes are had food, and have a tendency to cause disease of the liver. We advise you to give them some stimulant in the shape of bread and ale, and to feed on ground oats if you can get them; if not, on barley meal night and morning, with some whole corn in the middle of the day. From all falling ill at the same time, we should expect they picked-up something that disagreed with them. If you have reason to think we are right, give each bird a table-spoonful of castor oil. Rice is bad food, and has a tendency to cause very low condition, and, consequently, vermin. Alter your dietary. Give them some bread and milk in the morning, afterwards some chopped egg, also coarse cooked meat and pieces of fat cut small. Let the ribs be in a dry place, well open to the sun, and let the chickens have dust in which to dust themselves. The younger chickens if fed in the same way, are suffering from the same disorder. Give them strong camphor water to drink, and in bad cases give a pill of it to each chicken. We never hear of gapes, and if there is the slightest symptom of them, we have recourse to camphor, and have never known it fail.

FOWLS FOR EGGS AND CHICKENS (Bar).—We believe the Shanghaes will answer your purpose very well, but we prefer Brahmans. They are not better layers than the Shanghaes, but they are better table fowls. Both are very hardy.

BRAHMA-WEAK-LEGGED (A Subscriber, Wexford House).—Feed your fowls well, give them ground oats twice per day, any rough cooked meat you may have chopped up small. If you have no ground oats give them barley meal. They have somewhat outgrown their strength. Keep them in a dry place lest they should get cramped.

FOWLS FOR A THREE-ACRE GRASS RUN (Amateur).—Where fowls are kept on a comparatively small space, we always advise one breed. This saves much labour and painstaking, the fowls do better, and the produce is more valuable if at any time the stock is to be sold. Paradoxical as it may appear, fifty fowls will do half as well again if they have free run over three acres, as they would if they were divided into two twenty-fives, and confined to an acre and a half each. We do not think you can do better than keep Brahmans. They are very hardy, they are not large eaters, they are good layers, sitters, and mothers. To produce eggs profitably you must have them in the time of scarcity—that is, the winter. At that season few if any hens lay, but pullets do. Just as it has been said all that is not military is civil, so some people say all that are not cocks are pullets, only as distinctions of sex. Laying belongs to a certain age. As soon as the pullet has attained to hen's estate she begins to lay, whether it be November or May. Some allowance may be made for the time of year. Chickens grow faster and attain maturity earlier in the spring and summer than in winter. Thus it should be no great difficulty to arrange for a constant supply. Some breeds lay earlier than others. The earliest we know are Brahmans and Cochins. We have known these to begin at sixteen weeks. It is not desirable, as they always become in consequence stunted, and nature appears exhausted before she attains her prime. As a rule, you may look for eggs from these two breeds between twenty and twenty-four weeks old. Depending on these facts, you will easily see that to insure eggs at the scarce and therefore valuable time of year, you will have to arrange accordingly. February pullets lay in August; March pullets in September; April pullets in October; May pullets in November, and so on. The best food you can give is ground oats, if they are to be had, slaked with water; if not, barley meal. This supplies the morning and evening food. The mid-day repast should be of whole corn, barley, or maize, varied with such scraps as may be got together in a house. All stimulants and spiced food should be avoided. The difference between Light and Dark Brahmans exists only in colour.

MRS. F. CHESHIRE'S CHICKEN APPARATUS (Mrs. Hope).—We do not know where it can be purchased, nor any book in which it is described. Mrs. C. will, perhaps, send us information.

INSURING BIRDS (E. K., jun.).—We know of no insurance office that would insure either the life or safety of a bird for any sum either small or large.

CRENCESTER SHOW.—Mr. T. A. Dean had an extra second prize for Light Brahma chickens.
